Abstract

In this paper, a finite capacity Markovian single-server queuing system with discouraged arrivals, reneging, and retention of reneging customers is studied. The time-dependent probabilities of the queuing system are obtained by using a computational technique based on the 4th order Runge-Kutta method. With the help of the time-dependent probabilities, we develop some important measures of performance of the system, such as expected system size, expected reneging rate, and expected retention rate. The time-dependent behavior of the system size probabilities and the expected system size is also studied. Further, the variations in the expected system size, the expected reneging rate, and the expected retention rate with respect to the probability of retaining a reneging customer are also studied. Finally, the effect of discouragement in the same model is analyzed.

Keywords: time-dependent analysis, single server queuing system, discouraged arrivals, reneging, Runge-Kutta method, retention

Introduction

Queuing systems are used in the design and analysis of computer-communication networks, production systems, surface and air traffic systems, service systems etc. The study of queuing systems help to manage waiting lines and to construct an optimal system for balancing customer waiting time with the idle time of the server Gnedenko and Kovalenko (1989). The enormous literature in queuing theory is available where the customers always wait in the queue until their service is completed. But in many practical situations customers become impatient and leave the systems without getting service. Therefore, queuing systems with customers’ impatience have attracted a lot of attention. The study of customers’ impatience in queuing theory is started in the early 1950’s. Haight (1959) studies a single-server queue in steady-state with a Poisson input and exponential holding time, for various reneging distributions. Ancker and Gafarian [(1963a), (1963b)] analyze an $M/M/1/N$ queuing system with balking and reneging. In addition, the effect of reneging on an $M/M/1/N$ queue is investigated in the works of Abou El-Ata (1991), Zhang et al. (2006), Al Seddy et al. (2009), and Wang and Chang (2002). Kovalenko (1961) discusses some queuing systems with restrictions.

Queuing systems with discouraged arrivals are widely studied due to their significant role in managing daily queuing situations. In many practical situations, the service facility possesses

TIME DEPENDENT ANALYSIS OF A SINGLE_SERVER QUEUING MODEL

Volume 12, No 4 (47)
December 2017

1 Queuing Model Description

In this section, we describe the queuing model. The model is based on following assumptions:

1. We consider a single-server queueing system in which the customers arrive in a Poisson fashion with rate that depends on the number of customers present in the system at that time i.e. \( \lambda / (n+1) \).
2. There is single server and the service time distribution is negative exponential with parameter \( \mu \).
3. Arriving customers form a single waiting line based on the order of their arrivals and are served according to the first-come, first-served (FCFS) discipline.
4. The capacity of the system is finite (say \( N \)).
5. A queue gets developed when the number of customers exceeds the number of
servers, that is, when \( n > 1 \). After joining the queue each customer will wait for a certain length of time \( T \) (say) for his service to begin. If it has not begun by then he may get renege with probability \( p \) and may remain in the queue for his service with probability \( q \ (= 1 - p) \) if certain customer retention strategy is used. This time \( T \) is a random variable which follows negative exponential distribution with parameter \( \xi \). The reneging rate is given by

\[
\xi_n = \begin{cases} 
0, & 0 < n \leq 1 \\
(n-1)\xi, & n \geq 2 
\end{cases}
\]

2 Mathematical Model

Let \( \{X(t), t \geq 0\} \) be the number of customers present in the system at time \( t \). Let \( P_n(t) = P[X(t) = n], n = 0,1,... \) be the probability that there are \( n \) customers in the system at time \( t \). We assume that there is no customer in the system at \( t = 0 \).

The differential-difference equations of the model are:

\[
\frac{dP_0(t)}{dt} = -\lambda P_0(t) + \mu P_1(t) \tag{1}
\]

\[
\frac{dP_n(t)}{dt} = - \left[ \left( \frac{\lambda}{n+1} \right) + \mu + (n-1)\xi p \right] P_n(t) + \left( \frac{\lambda}{n} \right) P_{n-1}(t) + \left( \mu + n\xi p \right) P_{n+1}(t), 1 \leq n < N \tag{2}
\]

\[
\frac{dP_N(t)}{dt} = \left( \frac{\lambda}{N} \right) P_{N-1}(t) - (\mu + (N-1)\xi p) P_N(t) \tag{3}
\]

3 Transient analysis of the model

In this section, we perform the time-dependent analysis of a finite capacity single-server Markovian Queuing model with discouraged arrivals and retention of reneging customers using Runge-Kutta method of fourth order (R-K 4). The “ode45” function of MATLAB software is used to find the time-dependent numerical results corresponding to the differential-difference equations of the model.

We study the following performance measures in transient state:

1. Expected System Size (\( L_s(t) \))
   \[
   L_s(t) = \sum_{n=0}^{N} n P_n(t)
   \]

2. Average Reneging Rate (\( R_r(t) \))
   \[
   R_r(t) = \sum_{n=1}^{N} (n-1)\xi q P_n(t)
   \]

3. Average Retention Rate (\( R_p(t) \))
   \[
   R_p(t) = \sum_{n=1}^{N} (n-1)\xi p P_n(t)
   \]

Now, we perform the time-dependent numerical analysis of the model with the help of a numerical example. We take \( N = 10, \lambda = 2, \mu = 3, \xi = 0.1, \) and \( p = 0.4 \). The results are presented in the form of Figures 1-5. Following are the main observations:

In Figure 1, the probabilities of number of customers in the system at different time points are plotted. We observe that the probability values \( P_1(t), P_2(t), ..., P_{10}(t) \) increase gradually until they reach stable values except the probability curve \( P_0(t) \) which decreases rapidly in the beginning and then attains steady-state with the passage of time.

Figure 2 shows the effect of the probability of retaining a reneging customer on the expected system size in transient state. One can observe that as the probability of retaining a reneging customer increases, the expected system size also increases. This establishes the role of probability of retention associated with any customer retention strategy.

In Figure 3, the change in average reneging rate with the change in probability of retaining
a reneging customer is shown. One can observe that there is a proportional decrease in average reneging rate with the increase in probability of retention, $q$.

The variation in average retention rate with probability of retention is shown in Figure 4. We can see that there is a proportional increase in $R_R(t)$ with increase in $q$, which justifies the functioning of the model.

In figure 5, the impact of discouraged arrivals on the performance of the system is shown. We compare two single server finite capacity Markovian queuing systems having retention of reneging customers with and without discouraged arrivals. One can see from Figure 5 that the expected system size is always lower in case of discouraged arrivals as compare to the queuing model without discouragement.

4 Conclusions

The time-dependent analysis of a single-server queuing system with discouraged arrivals, reneging and retention of reneging customers is performed by using Runge Kutta method. The numerical results are computed with the help of MATLAB software. The effect of probability of retaining a reneging customer on various performance measures is studied. We also study the impact of discouraged arrivals on the system performance.
