Water steam content in the city center is reduced in comparison to its suburban areas that become especially noticeable in summer, since evaporation from asphalt and stone surface is low. Relative humidity is 10-15% less in summer in the central parts than in outskirts. Decrease of wind, increased cases of inversion, shift to the center of an air bringing admixtures from suburban areas, promotes admixture concentrations growth in the central part of the city. Extremely hazardous cases of air pollution in the city are observed during formation of fog and its variety – smog.

II. Methods

In order to evaluate atmospheric pollution in Tbilisi city, there have been used the materials of atmospheric air pollution monitoring of the National Environmental Agency, who carries out observation on air background pollution and measurements of aerosol and harmful substance concentrations in automatic mode. The work also makes use of indicatory measurement results for Tbilisi city.

The following polluting agent concentrations are measured citywide, namely: solid suspended particles PM10 and PM2,5, carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO2) and ozone (O_3).

Standard statistical, climatological and graphical analysis research methods are used for study. Data processing is based on the methods of multifactorial statistical analysis [16].

III. Results and Discussion

The research makes use of research results of the following polluting ingredients monitoring data (2022-2023, March) conducted at the atmospheric air observation automatic station located at Tsereteli Avenue, namely: solid suspended particles PM10 and PM2,5, carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO_2).

Tbilisi city environmental pollution degree was assessed based on atmospheric air observation and results of automatic station monitoring materials study. We made comparison and graphical analysis of materials of polluting ingredients ($PM_{2.5}$, PM_{10}, SO_2, O_3, NO_2 and CO) monitoring carried out in 2022-2023, March (Fig. 1, 2, 3, 4, 5); qualitative and quantitative comparison of anthropogenic sources of atmosphere pollution and identification of atmospheric air quality state.

We have established synoptical and meteorological conditions which caused smog registered in March 2023.

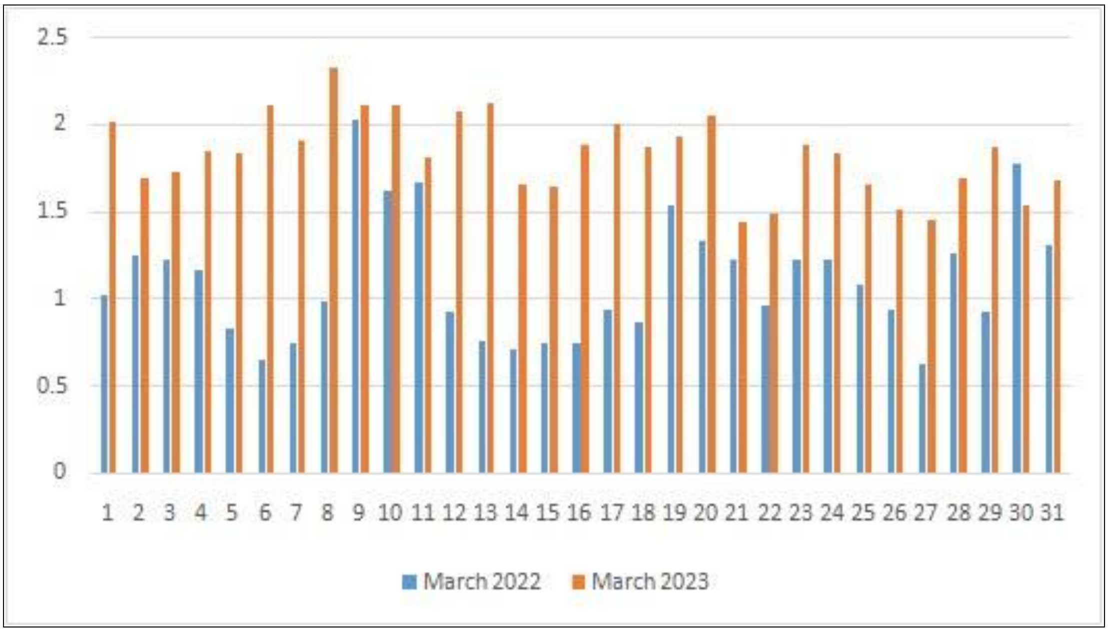

Figure 1: *Carbon Monoxide (CO) dynamics (March 2022 and March 2023)*

As is seen from the diagram, according to March 2023 data, carbon monoxide (CO) concentration over the course of a month surpassed the data of March 2022, though exceedance of the maximum permissible concentration was never recorded in any case. Main sources of CO entering into atmosphere are exactly vehicle emissions and natural gas consumption. Such concentration of carbon monoxide is presumably caused by city motor park upgrading and control over vehicles carried out by technical inspection. CO has a substantial impact on human health, in particular causes cardiovascular diseases, fetal development delay, while in case of inhalation in large amount a lethal outcome may come (Fig. 1).

Solid particles (PM10) dynamics is not stable. There are days, when March 2022 data prevail over March 2023 data and vice versa (Fig. 2). In both cases the situation is complicated enough. Taking into account that PM10 maximum permissible concentration is 40 mkg/m^3, it is clearly seen that in March 2022 concentration of solid particles (PM10) exceeded a limit. However, much more complicated situation was in March 2023, since concentration of solid particles was sharply increased and far exceeded the previous year level, in particular during 17 days. Especially should be noted the period from 8^{th} to 21^{st} of March, when solid particles concentration exceeded maximum permissible norms that was caused by frequent penetration of air masses from Kara-Kum desert to Georgia during the eastern process and as a consequence a smog was recorded in the period from $10^{th}$to 17^{th} of March. This is an emergency situation, since such a high content causes severe diseases in humans like eye irritation, asthma, bronchitis, tumors, intoxication etc.

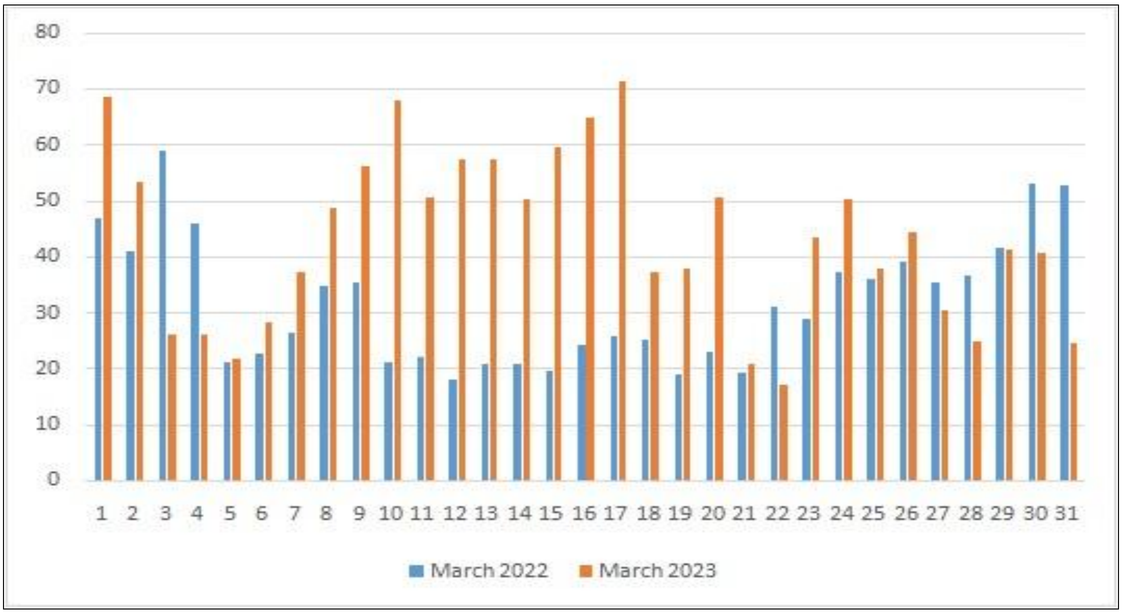

Figure 2: *Solid particles (PM10) dynamics (March 2022 and March 2023)*

Similar to PM10 particles, PM2.5 concentration exceeded MPC (Fig. 3). In both cases (2022-2023 March) the cases of exceedance of maximum permissible concentration were recorded. Maximum permissible concentration for PM2.5 is 25 mkg/m^3. In March 2022, PM2.5 concentration during 7 days surpassed the maximum permissible concentration (basically in the beginning of the month), while in 2023 – in the course of 22 days, mainly in the middle of month, from 10th to 20th March (that was caused by air mass entrance from Kara-Kum desert during the eastern process).

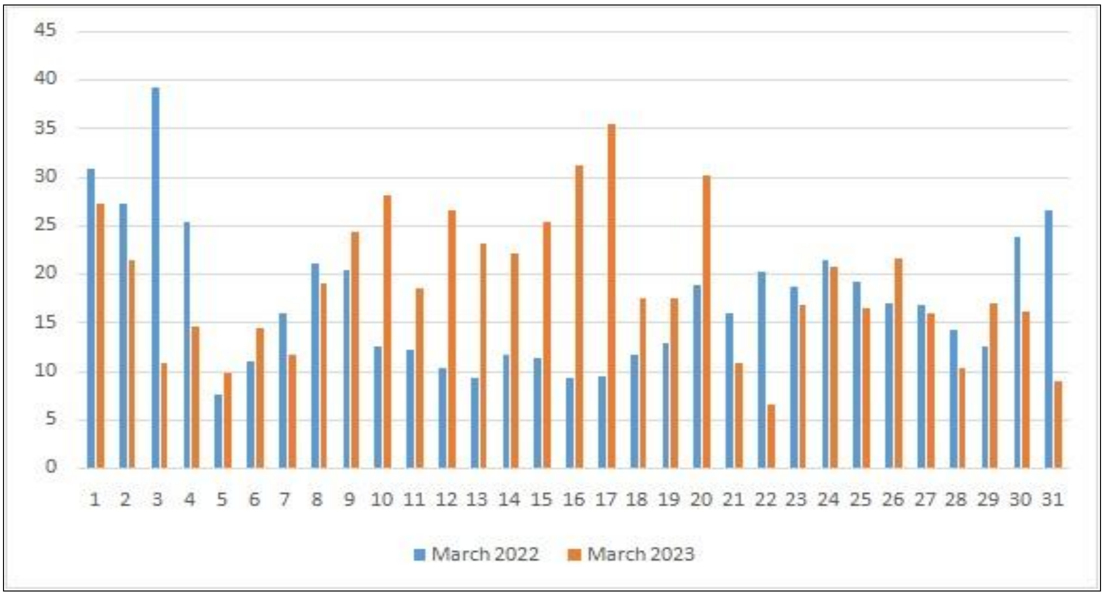

Figure 3: *Solid particles (PM2.5) dynamics (March 2022 and March 2023)*

Here one has to take into account the circumstance that PM2.5 particles are of very small size and respectively they are very light. As a consequence, they present in suspended state in the atmospheric air (due to very low sedimentation rate, since PM2.5 particle deposition rate is 10-time lower compared to PM10 particles). Small dispersive PM2.5 particles available in the air due to their small mass and size easily penetrate human lungs through respiratory passages; these particles are discovered even in the blood composition. Proceeding from this fact they can likely cause different types of diseases and, therefore, pose a threat to human health.

96% of urban population live in the environment of high concentrations of solid dust particles (PM2.5), which excesses WHO recommendations (5 mkg/m^3), while less than 1% - in the medium of such concentrations of PM2.5 particles, which surpass annual permissible level of 20 mkg/m^3 established by European Union.

The sulfur dioxide (SO_2) concentration decrease trend, not counting several days, is clearly seen from the diagram (Fig. 4). Maximum value 58.68 mkg/m^3 was recorded on 21st of March, 2022, while in 2023 the maximum was registered on 6th of March and was equal to 53.06 mkg/m^3. This state may be considered as satisfactory, since maximum concentration of sulfur dioxide according to these data approximately approaches (not exceeds) the maximum values. The mentioned circumstance is caused by the strict control over motor transport and by fuel quality check performed in recent years.

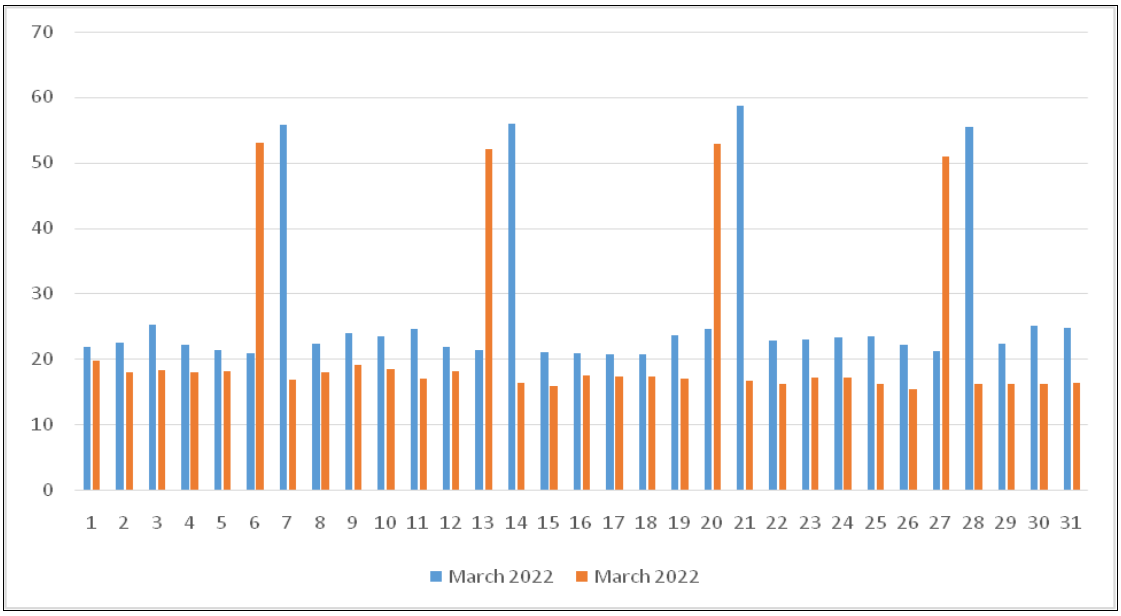

Figure 4: *The sulfur dioxide (SO_2) dynamics (March 2022 and March 2023)*

Nitrogen dioxide (NO_2) MPC equals to 40 mkg/m^3. It is well seen from the diagram (Fig. 5) that according to March data nitrogen dioxide concentration in both cases is more than 40 mkg/m^3 in the majority of days and approximately varies between 40 and 100 mkg/m^3, that 1.5-times exceeds maximum permissible concentration. The mentioned circumstance may be caused, as it was already mentioned, by features of circulation processes peculiar for the region and by frequent cases of inversion and isothermy. Pollution level in the surface layer increases under mentioned conditions. It is also important that aerosol concentrations growth under these conditions leads to ozone concentration increase and formation of photochemical smog, as a result.

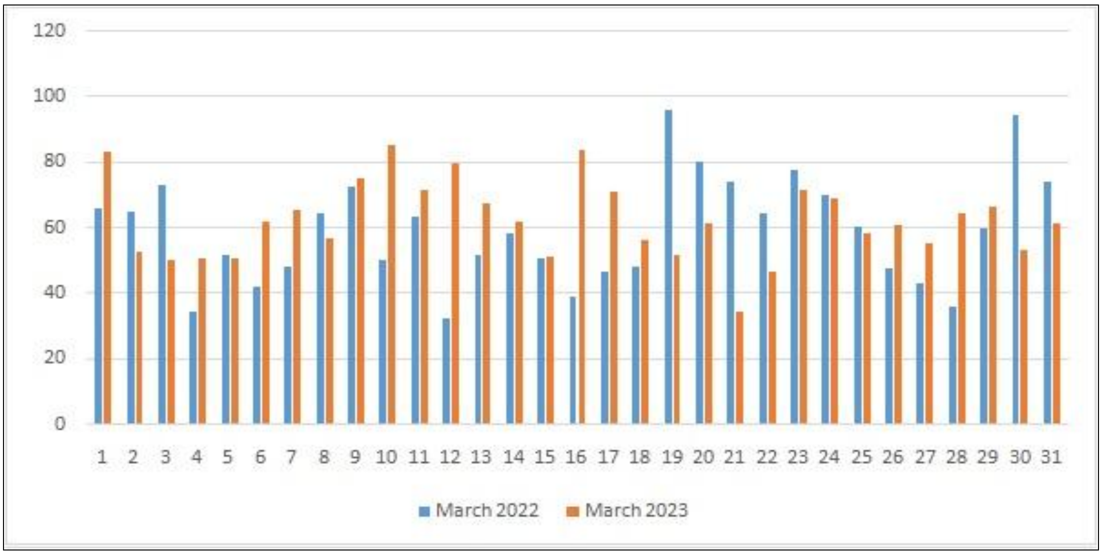

Figure 5: *Nitrogen dioxide (NO_2) dynamics (March 2022 and March 2023)*

IV. Conclusions

- Ecological state of the atmosphere depends on pollution source specificity and power, as well as on microclimatic, physical-geographical, and meteorological conditions peculiar for this place, and the most important, on the level of economic development and environmental awareness of the country.
- Maximum concentration (78%) of atmosphere polluting substances under Tbilisi conditions is caused by high intensity of motor transport use, and by physical-geographical, microclimatic and meteorological conditions.
- Solid particle concentrations were rapidly increased in March 2023 that was stipulated by the frequent penetration of air masses from Kara-Kum desert to Georgia, as a consequence of which a smog was recorded for several days.
- According to National Environmental Agency data, due to air masses (desert dust) invasion, a daily rate of PM10 particles at the Tsereteli Avenue was exceeded 47-times in 2022, and 78-times – in 2023.
- According to National Environmental Agency data, in some cases nitrogen dioxide (SO2) content at the Tsereteli Avenueis 10-times higher compared to other territories.
- Under conditions of Georgia, there is established a negative impact of atmosphere pollution on human health, and meteotropic diseases, malignant tumors, mutation etc are revealed.
- It was established by the studies that a synoptic situation the most peculiar for Tbilisi, during which a total pollution increases, is a high-pressure baric field (anticyclone), which is mainly associated with stationary cyclone of Kazakhstan, Western Siberia or Eastern Siberia. During the mentioned situations, concentrations of polluting agents in the atmosphere of Tbilisi increase almost in all cases. Wind velocity near the Earth surface is less than 5 m/sec; front and stream flow effect is not observed, and wind velocity is decreased at a height, as well; turbulent mixing is weak and equals to 1-3 m/sec; there are frequent cases of inversion and isothermy. Under the mentioned conditions, pollution level in the surface layer increases.
- Air quality deterioration in March, 2023 in Tbilisi was caused by increase in solid particles content. The World Health Organization considers that the smallest dust particles present in the air, concentration of which at this moment in Tbilisi exceeds maximum permissible level, more than other pollutants do damage to human health. Their inhalation heightens the risk of cardio-vascular and respiratory diseases, as well as lung cancer.

Abstract

This article is devoted to the study of the essence of environmental education, which plays a very important role in the formation of an individual's ecological culture, as well as a person's caring attitude towards nature and the environment. The main goals and tasks of the category under consideration are aimed at the development of environmental thinking, and a better understanding of the relationship between nature and man, which affects the formation of an individual's ecological behavior. In addition, to achieve these goals and tasks, the basic principles of ecological behavior come to the rescue, in particular, a practical orientation, a systematic approach and the conditions of the local environment.

Undoubtedly, the availability of qualified personnel to train both the younger and older generations plays a very important role in the formation of a cult of personality, responsible for his/her actions and benefiting nature. But, unfortunately, at the present stage of human development, environmental education faces a number of problems, in particular, the lack of an adequate level of funding, appropriate personnel, the absence of merging ecology with other sciences, etc., which require prompt intervention and solutions. In our opinion, in the near future it is necessary to make environmental education a priority in order to achieve sustainable development and protect natural resources for future generations.

Keywords: ecology, environmental education, environmental training, ecological culture, ecological thinking, environment, natural management

I. Introduction

The emergence of such a science as ecology dates usually back to 19th century, during which the considered category served as a certain component of such a broad concept as zoology and studied the relationships within the environment.

But, as practice shows, with the development of civilization, the main direction of ecology also changes, to a greater extent, flowing into the social aspect.

Now the role of ecology is being studied in the context of science that helps people survive under environmental conditions and make this environment as "comfortable" as possible for existence.

Unfortunately, human resources and the importance of clean ecology were realized only after an obvious conflict with the negative consequences of people's careless attitude towards nature, which, first of all, had a negative impact on people's health.

Accordingly, in modern conditions of development of society and the entire civilization, there is much concern about improving the quality of education, covering issues of the ecological environment, which is called environmental education.

In our opinion, before studying this term, it is important to focus our attention on the four well-known laws of ecology, which were put forward by the American scientist B. Commoner in the early 70s and became known under the slogan of the following aphorisms [1, 4].

So, let's consider the basic laws of ecology proposed by him:

1. "Everything is connected to everything else." The essence of the first law of ecology is interpreted in the context that all phenomena and processes in nature are closely interconnected. That is, this law "teaches" people to live without injudicious actions on individual parts of the ecological system, which can lead to global consequences.

2. "Everything must go somewhere." The second law states that any waste from economic activities must either be minimal or must go through a secondary usage cycle.

3. "Nature knows best." The third law of ecology focuses on the reasonable and conscious use of available natural resources. This law teaches people to cooperate with nature, instead of trying to completely transform it, and reminds us that we, humans, serve as an integral part of nature itself, but not its conqueror.

4. "There is no such thing as a free lunch." This is exactly what the latest Commoner Law says. After all, everything that we take from nature, we are obliged to compensate

For clarity, we would like to demonstrate the main 4 laws of ecology using by Barry Commoner 1917–2012, American biologist and ecologist:

1. Everything is connected to everything else.
2. Everything must go somewhere.
3. There is no such thing as a free lunch.
4. Nature knows best.

Undoubtedly, these laws play a key role in our life, although many of us are not even aware of it.

II. Materials and methods

We have to deal with environmental information almost every day in such areas as medicine, culture, education, etc.

But, unfortunately, the population usually doesn`t know how to correctly assess this or that emerging problem, due to the fact that it doesn`t have the proper qualifications and competence.

In this connection, the introduction of environmental education in people's lives is becoming highly relevant.

Thus, the main aim of environmental education is to create the most conscious, reasonable, positive attitude of a person towards nature and the environment, as well as the establishment of various interrelations between them.

The following tasks can be considered as the main tasks of environmental education [12, 15]:

- ✓ Extension of knowledge in the field of ecology for better understanding various environmental terms and concepts;
- ✓ Increasing the level of interest in environmental conservation among the population;
- ✓ The introduction of knowledge and skills for a proper attitude to nature;
- ✓ An increase in the level of environmental literacy among both the younger and older generations;
- ✓ Fostering a humane attitude towards nature;
- ✓ Increasing the level of competence in the study of various objects and phenomena;
- ✓ Upgrading the existing skills in helping the environment;

✓ Development of the qualities of competent analysis of all consequences of the environmental environment.

That is, for the formation of environmental education it is important to have environmental consciousness, because these terms are interrelated.

As for the methodology of environmental education, it is necessary to consider the complex of methods that are used to achieve the set goals and objectives.

The methods of environmental education are chosen depending on pedagogic and educational tasks, as well as the age criteria of students.

So, it is customary to distinguish the following methods of environmental education [5]:

✓ Visual methods, the essence of which is to study natural objects in real life or using images. Various types of observations, both live and with the help of illustrations, serve as vivid examples of this method. For example, observing the growth of plants or the behavior of animals;

✓ Verbal methods, including conversations, stories, reading information about ecology. Here, in our opinion, an important role is given to works of art, which clearly describe those processes of nature that become impossible to see;

✓ Practical methods covering various practical tasks and exercises. These methods usually include modeling, design, experiments, games, etc.

The terminology of environmental education was first discussed at a conference in the USA in the 70s of the XX century.

At that time, the following definition of this term was put forward: "Environmental education is the process of a person's awareness of the value of the environment and clarification of the basic regulations necessary to obtain the knowledge and skills necessary to understand and recognize the mutual dependence between man, his culture and his biophysical environment. Environmental education also includes the development of practical skills in solving problems related to interaction with the environment, developing behavior that contributes to improving the quality of the environment" [11].

According to Yu.L. Khotuntsev, the main goal of introducing environmental education in schools is to form in individuals the correct views and beliefs, covering the norms of moral responsibility of individuals for the state of the environment and for its improvement.

In other words, the main significance of environmental education is to teach people to make the most rational and effective decisions to protect the environment, based on moral norms and values [7].

A well-known expert in the environmental field I.D. Zverev offers a similar interpretation of this category, defining it as "... a continuous process of education, training, and personal development, aimed at forming a system of knowledge and skills, value orientations, moral, ethical and aesthetic relations, that ensure the environmental responsibility of an individual for the condition and improvement of socio-natural environment..." [9].

In his opinion, the main pedagogical tasks of environmental education include the following stages:

✓ Training is acquiring new knowledge about the environment;

✓ Education is introduction of moral qualities, guidelines, habits for environmental protection;

✓ Development is the ability to competently analyze the resulting environmental situation.

That is, as we see it, there is a fairly close relationship between environmental education and environmental training, which is a certain mechanism that ensures the presence of certain fundamentals of caring for nature and the environment in individuals, as well as the most rational use of natural resources.

Accordingly, in turn, the key component of environmental training is environmental consciousness, which is a complex phenomenon and evolves through the development of the intellect, emotions and desires of students.

So, as for environmental consciousness, the following factors take place [2]:

✓ Having an interest in problematic aspects of the environment

- ✓ Having a sense of responsibility towards nature;
- ✓ Willingness and readiness to participate in environmental activities;
- ✓ Concern about the environmental views of the population.

In turn, the structure of consciousness includes a number of environmental values that play a key role in the formation of certain norms of ecological behavior of people.

Accordingly, as we see it, ecological behavior is formed on the basis of various actions and views of a person on certain actions, which are directly related to the goals and motives of the individual [10].

We`d like to note that, according to A.A. Pavlov, the modern younger generation, unfortunately, does not particularly have environmental values in matters of careful natural management and preservation of the entire environment.

Thus, to sum up all the mentioned above, we can conclude that environmental education acts as an important tool in the pedagogical process for the formation of certain knowledge and skills that help to form in the individual the most important qualities necessary for a responsible and careful attitude towards nature.

In other words, an important task of environmental education and training is the creation of a developed ecological culture.

Some scientists identify these terms with each other. Others, on the contrary, believe that environmental education is formed only through the presence of ecological culture.

For example, V.A. Yasvin considers ecological culture in the context of people's abilities to use personal knowledge and skills in the field of ecology at a practical level.

After all, many people, even having a lot of knowledge, do not have the ability to use it competently due to the lack of the necessary level of ecological culture.

In this regard, environmental education of the population is becoming more relevant. It consists in disseminating knowledge about environmental safety, healthy lifestyle, the state of the environment, etc. [16].

III. Discussions

Thus, as we see it, the role of environmental education in the modern world is constantly increasing. But, unfortunately, in the process of development it faces a variety of problems that require prompt solutions to increase the effectiveness of the entire educational cycle.

We`d like to note several main problems of environmental education.

First of all, we`d like to start with the factor of insufficient awareness of existing environmental problems. Indeed, very often people do not realize the scale and seriousness of certain environmental situations, which undoubtedly have a direct or indirect impact on our lives.

In our opinion, this phenomenon may be connected with the fact that the population does not adequately own the entire information base and does not have a correct understanding of nature and the environment.

And the task of environmental education is to instill knowledge about careful attitude towards nature, as well as a sense of responsibility for its well-being, in people's minds.

As for education, in our opinion, the absence of merging ecology with other disciplines is also an important problem.

After all, environmental education is most often considered as a completely separate discipline, without showing the connection between it and other subjects, which is the wrong decision [13, 14].

Therefore, it is necessary to integrate the object of our research at all levels of education, in order to explain to students the close relationship between ecology and other sciences [8].

A negative factor is the absence of appropriate personnel who could teach the younger generation to environmental friendliness.

To do this, in our opinion, additional classes and trainings are needed to prepare the best specialists in environmental education.

And finally, another acute problem is the lack of funding, which is necessary for conducting excursions, purchasing equipment and materials, etc. [3].

In this regard, it is important to ensure the appropriate level of funding for the object of our research for its further development and prosperity [17].

IV. Results

Thus, having considered the main problems of environmental education, we would like to dwell on promising directions for its development.

First of all, we`d like to start with the formation of ecological thinking, the essence of which lies in the ability of students to see the connection between certain components of nature and understand their interrelation.

With the help of ecological thinking, an individual gets the opportunity to make the most effective management decisions and function in defense of the interests of the environment.

Also, as a perspective, we would like to note the formation of sustainable behavior skills, which consist in the most rational use of available natural resources, in particular, production waste sorting, reducing energy costs, etc.

These actions will serve as a certain incentive for students in matters of preserving the environment and increasing the level of responsibility for their actions.

Careful attitude to the conservation of various living organisms also serves as a perspective for the development of environmental education.

And finally, the development of environmental education is accompanied by the development of ecological culture among the population, which plays a key role in environmental protection due to various norms and values.

That is, there is an increase in the level and quality of people's knowledge about environmental ethics, a fair and careful attitude towards natural values.

V. Conclusions

Thus, based on the above-mentioned, we can conclude that environmental education has quite a serious development potential in order to solve various global environmental problems and ensure a decent future.

But, unfortunately, at the present stage of development of society and the economy, environmental education faces a number of problems in matters of training appropriate personnel, financing and absence of its merging with other disciplines that require prompt solutions.

After all, only by solving at least the basic problems of environmental education we will be able to see the potential of environmental education and its benefits for all humankind.

Abstract

The article presents a comparative analysis of attitudes towards environmental issues in real life and in the digital environment. The authors attempted to evaluate 10,000 statements regarding environmental issues by VK users not only from the point of view of content analysis, but also from the point of view of the psychological characteristics of this digital trace of individuality. On the other hand, when analyzing attitudes towards environmental issues in real life, we applied traditional methods of psychological personality diagnostics, which were taken by 80 VK users. To compare the results obtained, we used data from the diagnostics of emotional attitudes - positive, negative and neutral. The results obtained in this study allow us to evaluate and compare attitudes towards environmental issues in real life and the digital environment, which contributes to understanding and identifying ways to solve problems of the ecosystem as a whole.

Keywords: digital trace of individuality, environmental issues, digital environment, VK users, emotional attitude

I. Introduction

Currently, one of the most burning topics in public discussion is the topic of ecology. In some aspects, these problems sometimes act as triggers to draw attention to the risks and real threats to the entire ecosystem. However, there are also "excesses" in assessing problems. An example is the problem of global warming, which environmentalists talk about as a fact that has happened more than once in the history of the earth, and is practically not related to environmental pollution.

Psychologists are particularly interested in the attitude of society (both real and digital) to environmental issues. The relevance of studying attitudes to environmental aspects of life is that it is necessary to know and control the degree of an individual's emotional reaction to pressing issues related to changes in the living environment of a modern person. Starting with the problems of the thinning of the ozone layer and ending with people's dissatisfaction with the proximity of settlements to landfills or the fact that neighbors have too many pets and do not take care of them. The modern educational and upbringing system provides many courses to improve environmental literacy. However, in real life, and even more so in digital reality, society actively and emotionally reacts to problems on the one hand, and, on the other hand, shows its attitude to the world around it. At the same time, people's reactions can indicate both a healthy and constructive attitude, and a destructive and harmful attitude to the environment. In this paper, we examined the psychological characteristics of attitudes to environmental problems, both in the real world and in the digital environment.

II. Methods

The study was conducted in September 2024 at the Pyatigorsk State University. In our study, we used two different approaches, since it is impossible to apply the same diagnostic methods to the real world and the digital environment.

So, to assess the attitude towards environmental issues in the digital environment, we received an unload of 10,000 statements by VK users on this topic. We processed these statements on the Polyanalyst platform [1], which provides the technical ability to identify the tone of statements, determine keywords, terms and establish connections between them [2; 3]. Such a technique allows us to characterize the digital trace of individuality, to characterize it in the digital environment. [4] This opportunity was provided to us by the developer of the Polyanalyst platform - Data - Diving Academy , the University Consortium of Big Data Researchers at Tomsk State University.

To diagnose attitudes towards environmental issues in the real world, we used valid diagnostic methods – the Method of Diagnosing Motivation for Interacting with Nature "Alternative"; the Scale of Environmental Concern and the Method of "Differential Emotions Scale"[5]. VK users took this diagnostic. We used statistical data analysis to process the data obtained.

In the third stage of our research, we conducted a comparative analysis of the obtained data.

III. Results

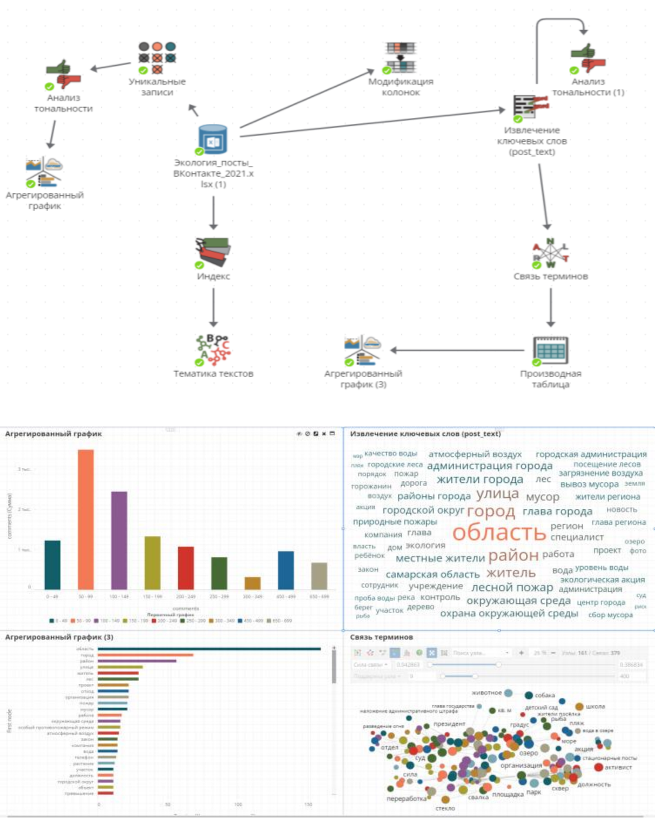

Figure 1: *Project and dashboard for analyzing environmental statements in VK*

Fig. 1 shows the results of the analysis of 10,000 statements by VK users. Working on the Polyanalyst platform and using the functionality of various nodes, we identified a number of features that can be interpreted from a psychological point of view. Thus, analyzing the data of the "Keyword Extraction" node, we define the following as the main keywords: "region", "mayor", "city", "district"; and secondary keywords - "garbage", "environmental protection", "forest fires", etc. This fact indicates that VK users, speaking out about environmental problems, more often define the priority for government representatives in responsibility for solving problems. These data are confirmed by the data of the "Aggregated Graph" node.

By defining the features of the connection of terms in the corresponding node, and relying on the indicators of the number of connections and the strength of connections, we identified the following priority connections - waste-landfill-site-plastic; atmospheric air-pollution-maximum permissible concentration; citizen-fine-waste incineration; recycling-processing-glass. These chains define the main topics in the discussion, they can be considered as the main triggers.

Particular attention should be paid to the data of the "Sentiment Analysis" node. For our study, it is necessary to determine the emotional background - positive or negative - of the statements of network users. The tonality of the statements was determined automatically and it turned out that there are 1.8 times more negative statements than positive ones.

In the second stage of our research, we present an analysis of a block of methods that were completed by 69 real respondents – VK users.

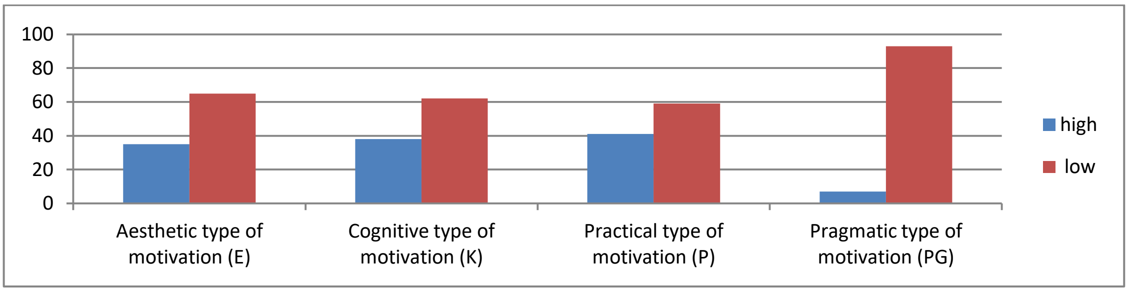

Figure 2: *Results of the Methodology for Diagnosing Motivation for Interaction with Nature "Alternative" (%)*

According to the data presented in Fig. 2, we see that the overwhelming majority of respondents showed a low level of motivation for their attitude towards the environment and its problems, which indicates that respondents are not inclined to be interested in nature, enjoy it, and try to solve environmental pollution problems. The overwhelming majority of respondents are more concerned with themselves and their concerns. In comparison with the results of the analysis of statements, we can trace the coincidence of attitudes towards the environment. VK users tend to consider the administration and officials to be the main ones responsible for the state of the environment. The users themselves are not inclined to admire or learn about the environment around us.

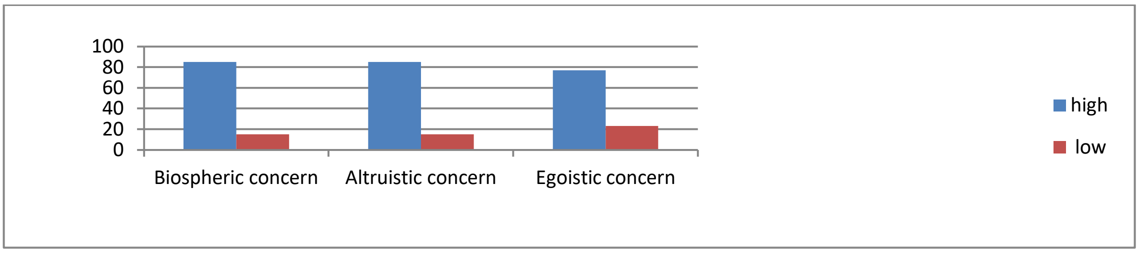

Figure 3: *Results for the Environmental Concern Scale Methodology (%)*

Fig. 3 shows the results of the "Scale of Environmental Concern" Methodology. It is obvious that high scores were obtained for all scales , which indicates concern about the fate of animals, birds and the ecosystem as a whole, as well as concern about the impact of environmental problems on children, people who live in the same region with me. A lower level is observed for the "Egoistic Concern" indicator - everything that concerns the consequences of environmental problems for one's own health, one's own lifestyle and future. Such scores indicate a high level of involvement in understanding the consequences of environmental problems in real life. In the digital environment, we can state an identical attitude and concern.

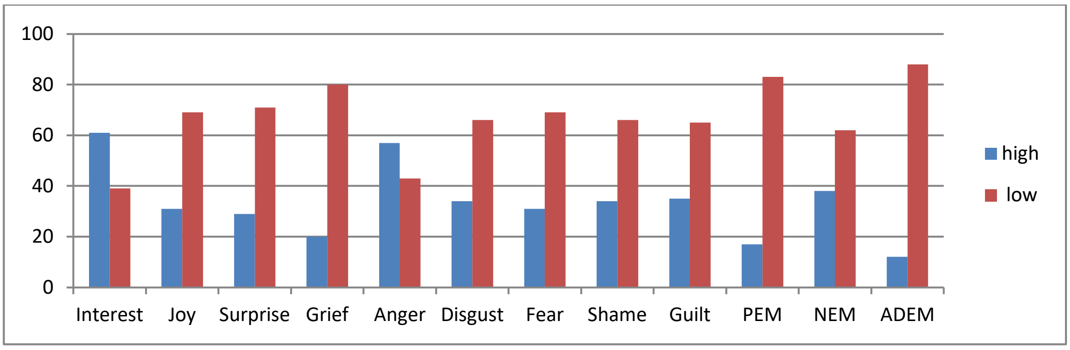

Figure 4: *Results for the "Differential Emotions Scale" method (%)*

Characterizing the data presented in Fig. 4, we determine the level of emotion that respondents showed regarding the current situation. In the block of positive emotions, "Interest" prevails, which is confirmed by the "Cognitive motivation" indicator regarding environmental problems. In the block of negative emotions, the data on the "Anger " indicator prevails, which is approximately half the results for the "Disgust" and "Fear" indicators. In general, the overall index of positive emotions is extremely low - about 19%, while the level of negative emotions is about 40%. This picture is also observed in the digital environment, where the level of positive tonality of statements is 1.8 times lower than the level of negative tonality of statements.

IV. Discussion

Modern studies of environmental problems affect various spheres of human activity and the whole society as a whole. In the work of E.A. Kharcheva the level of awareness of the population about the existence of various kinds of environmental problems is studied, and the level of environmental culture of the population of Russia and Europe is determined [6]. In the study of N.V. Kochetkov the components of the subjective attitude of young students to environmental problems are determined [7]. The scientist notes that if for the overwhelming majority of the population the determining component of the subjective attitude to environmental problems is the emotional component, then for students connected with environmental problems within the framework of their educational and cognitive activities, the components of a practical and cognitive nature act as key and decisive. In the study of O. Ogarkov the influence of environmental crises on the individual was revealed [8]. The study showed that the psychological consequences of environmental crises can be varied and include the following aspects: stress and anxiety, deterioration of physical and mental health, feelings of helplessness and fatigue, and changes in attitudes toward nature. The study shows that overcoming these negative psychological consequences of environmental crises is possible with the help of psychological, educational, personal strategies, and strategies to reduce the negative impact on the environment [8]. Social and psychological research abroad also raises the issue of the relationship and mutual influence of environmental and personal problems [9].

However, in modern research there has not yet been an attempt to study the digital trace of individuality in relation to the holistic structure of individuality in its relation to environmental issues. The authors of the article plan further research in the direction described in this study

Abstract

The development of new Arctic regions in the context of global and local thawing of permafrost soils caused by both local man-made and global natural thermal impacts on the ground necessitates the use of new engineering solutions for the timely prediction and prevention of dangerous uneven deformations in buildings. Uneven building deformations occur due to the reduced stiffness of the soil mass beneath the foundation, caused by the uneven thawing of the soil. It is proposed to assess the stiffness of the "soil-building" system using the dynamic-geophysical testing method.

Keywords: "soil-building" system, dynamic-geophysical testing, natural vibration frequencies of soils, vulnerability of the "soil-building" system, technical condition of the "soil-building" system

I. Introduction

In the Far North, modern multi-story construction has been employed for many years, and it is in no way different from construction in regions without permafrost. However, the use of modern engineering life support systems creates a significant thermal load on the soil mass beneath the buildings, which can lead to uneven thawing of permafrost soils, causing uneven settlement and deformation of the structural framework of buildings (see Figure 1). To prevent potential damage to buildings caused by uneven thawing of the soil, additional diagnostic and monitoring methods are required. These methods should allow for the timely identification of hazardous zones in the soil mass during the investigation, construction, and operational stages, which could lead to deformations in the "soil-building" system [1].

Due to the influence of possible heterogeneities in the soil mass, there is a loss of equilibrium and stability, leading to subsidence, landslides, disruption of hydrological regimes, suffosion, karst phenomena, increased deformation of the "soil-building" system, and a heightened risk of building and structure collapse. To detect potential geological hazards beneath the foundation of a building, investigative methods capable of assessing the soil mass up to depths of 50-100 meters are required [2].

Known geological and geophysical methods do not allow for the quick and reliable determination of the location and magnitude of geological heterogeneities (see Table 1). Geological drilling with soil sampling is a point-based investigation, and to obtain accurate data on the structure, physical and mechanical characteristics, and potential geological hazard zones, the number of boreholes must be maximized, which is impractical in reality. The use of geophysical methods, such as seismic exploration, improves the quality of geological surveys; however, these studies are limited to two-dimensional linear profiles of up to 50 meters in length and 20 meters in depth. The depth of research can be increased by extending the wave source, but this requires additional time and financial resources. The greatest challenge, however, lies in the interpretation of geophysical data and identifying potential geological hazards, which depend solely on the expertise of the geophysicist [3].

Figure 1: *deformation of a building in arctic conditions due to uneven settlement of the "soil-building" system*

Table 1: *comparison of geological and geophysical methods for investigating the physical-mechanical and dynamic parameters of the soil mass beneath buildings and identifying potential geological hazards.*

Criteria	Geological Methods (Drilling and Sampling)	Geophysical Methods (e.g., Seismic Exploration)
Depth of Investigation	Limited to specific borehole depth (can reach 50-100m)	Typically up to 20m, but can be extended with additional efforts
Data Accuracy	High at specific borehole locations	Moderate; relies on interpolation between points
Coverage	Point-based, requires multiple boreholes for broader coverage	Provides continuous profiles along a line, but limited in area
Physical-Mechanical Data	Direct sampling allows precise measurement of soil properties	Indirect; requires interpretation of wave propagation data
Dynamic Soil Properties	Limited, usually not assessed directly	Provides information on soil stiffness, natural frequencies
Geological Hazard Detection	High precision at the borehole location, but limited coverage	Identifies anomalies, but exact nature requires interpretation
Cost	Expensive (especially with a high number of boreholes)	More cost-effective for larger areas, but requires specialized equipment
Time Required	Time-consuming due to drilling and sample analysis	Faster than drilling for shallow studies, slower for deeper studies

Applicability in Complex Terrains	Limited by access for drilling equipment	More flexible; can cover larger and more difficult terrain
Interpretation Dependence	Minimal; results are based on direct soil properties	High; depends on the expertise of the geophysicist
Hazard Detection at Depth	High, but localized to borehole	Moderate, dependent on the depth capability of the equipment

It is proposed to use the dynamic-geophysical testing method for assessing the stiffness parameters of the "soil-building" system.

II. Methods

The experience of applying the dynamic-geophysical testing method shows that, by considering the soil mass as a vibrating body with specific dimensions and depth, one can roughly determine its structure and physical-mechanical characteristics depending on the predominant soil composition and the natural vibrations of the mass.

The technology of dynamic-geophysical monitoring of the "soil-building" system has been widely tested on various objects. This technology allows detecting possible changes in the system's condition. It has been successfully applied for diagnosing "soil-building" systems to identify the risk of building collapse in locations such as Novy Urengoy, Muravlenko, Nizhnevartovsk, the Bryansk region, Yakutia, Altai, the Kamchatka region, Sakhalin, the Ulyanovsk region, and others.[4]

The proposed comprehensive dynamic-geophysical monitoring technology is an integrated measurement and analytical system installed in areas with potential geological hazards. The system consists of a computer with specialized software that collects, analyzes, and processes digital data from sensors placed in the monitored zone according to specific criteria. The system includes a multi-channel analog-to-digital converter (ADC), three-component accelerometers, tilt sensors, water level and pore pressure sensors in the soil, temperature sensors, and others, along with a cable or radio data transmission system from the sensors to the ADC. The composition and number of necessary monitoring system elements are determined based on the monitoring goals.[5]

The criteria developed with the participation of the authors for assessing the stability of the soil mass using the results of dynamic-geophysical observations allow the early detection of unstable equilibrium states of the soil (within hours to days). A sensitive stiffness parameter of structural systems is vibrations. Vibrations of the soil mass, like those of structures, depend on their mass and stiffness. For the soil mass, the equation linking its vibrations to its geometrical and physical-mechanical parameters can be expressed as follows:

$$T_1 = 2{,}63 \times \mathrm{H}\sqrt{\frac{\rho}{G}}, \ (1)$$

where:

ρ is the density of the considered block of the soil mass,

G is the shear modulus of the soil mass,

H is the height of the block of the soil mass.

The most convenient parameter for measurements and calculations is the natural frequency of vibrations, which is the inverse of the vibration period. Each type of soil with uniform thickness is characterized by a certain level of weighted average period or frequency of vibrations. The values of fsv vary depending on the thickness, size of the soil mass, and type of soil. For example, for soil with a thickness of 8-10 meters,Tpr = 4H/vs Table 2 provides the physical-mechanical and dynamic parameters of soils.

Thus, by monitoring the period (frequency) of vibrations of the object or the soil mass, it is possible to control their stiffness, including the degree of soil saturation. The stiffness of the soil mass and the building is directly proportional to the squares of the frequencies in the monitored directions.

Table 2: *physical-mechanical and dynamic parameters of soils.*

Soil Type	Density (ϱ), t/m³	Shear Modulus (G), MPa	Elastic Modulus (E), MPa	P-Wave Velocity (Vp), m/s	S-Wave Velocity (Vs), m/s	Natural Frequency of the Soil Mass (f), Hz
Sand	1.6	33.54	15.9	200-500	150-300	2.86
Sandy Loam	1.6	60.38		250-550	120-280	0.7
Loam	1.7-1.75	26.71	5.06	300-600	100-250	1.25
Clay	1.8-2.05	48.16	7.1	1400-2500	400-600	2.1
Wet Clays	Less than 1.5	3-6	1.5	1400	100	1

Thus, to assess the stiffness of the "soil-building" system, it is necessary to:

1. Select locations for sensor placement and perform tests on the "soil-building" system.
2. Obtain the natural frequencies of the "soil-building" system.
3. Calculate the normative values of the natural frequencies of the soil mass beneath the building and the building itself.
4. Calculate the normative values of the natural frequencies of the monitored load-bearing structures.
5. Compare the squares of the natural frequencies of the soil mass and the building, and determine the stiffness deficits by direction.
6. Using the criteria, evaluate the technical condition of the soil mass and the building.

III. Results

In a kindergarten building constructed with a precast reinforced concrete frame and located in Arctic conditions, structural deformations began to appear during its operation due to soil weakening in the foundation caused by thermal exposure. To assess the stiffness of the "soil-building" system, the dynamic-geophysical testing method was applied. For soil assessment, three-component accelerometers of type A1638 were used. By sequentially placing the sensors on the pile cap foundations in the building's basement, as well as on the floors and roof of the building, the natural vibration frequencies of the "soil-building" system were obtained. [5]

Figure 2: *Kindergarten Building Tested Using the Dynamic-Geophysical Method.*

To assess the technical condition category of the building, a comparison was made between the normative values of the building's natural vibration frequencies and the experimentally obtained values.

The potential reduction in the building's stiffness is determined by comparing the normative and experimentally obtained natural vibration frequencies.

Stiffness deficiency is assessed using the following dependencies [4–8]:

$$\Delta fx = ([fx]^2 - fx^2) \times 100 / [fx]^2, \quad (1)$$

$$\Delta fy = ([fy]^2 - fy^2) \times 100 / [fy]^2, \quad (2)$$

$$\Delta fz = ([fz]^2 - fz^2) \times 100 / [fz]^2, \quad (3)$$

where fx, fy, fz are the values of the building's natural vibration frequencies obtained from dynamic tests.
[fx], [fy], [fz] are the standard natural vibration frequencies obtained from the design or calculated values.
Δfx, Δfy, Δfz are the stiffness deficiencies in percentages along the X, Y, Z axes (see Table 2).

Table 3: *Percentage of stiffness reduction (square of the building's natural vibration frequency), depending on the category of technical condition.*

Type of Structure	Percentage of Relative Stiffness Reduction of a Structure in Various Conditions				
	Very good	good	fair	poor	very poor
Reinforced Concrete Frame	0–25	25–43	43–57	57–71,4	71,4–100
Steel Frame	0–16,7	16,7–33	33–50	50–67	67–100
Brick	0–16,7	16,7–33	33–50	50–75	75–100
Wooden	0–20	20–27	27–40	40–67	67–100
For Other Types of Buildings and Structures, Soil Masses Beneath Buildings	0-10	11-30	31-60	61-90	

Based on the test results, the following conclusions were made: The building is in operational condition; however, resonance frequencies between the soil and the building were detected, which may lead to increased vibration amplitudes and the development of structural damage.

To assess possible heterogeneities, loosened areas, and likely zones with reduced soil stiffness, dynamic-geophysical testing was conducted in the building's basement. In Figure 3, the zoning of the soil mass beneath the building is shown. In red zones, stiffness reduction can reach up to 50%, while in yellow zones, it can reach up to 30%. At least two high-frequency anomalies are recorded in the red zones along the axes, while one anomaly is recorded in the yellow zone.

The example considered demonstrates that timely detection of potential zones of stiffness reduction in the soil can be ensured by:[6]

1. Monitoring the soil mass condition to promptly determine its dynamic-geophysical parameters and prevent resonance phenomena from dynamic impacts;
2. Comprehensive monitoring of the "soil-structure" system (parallel control of water levels in boreholes, monitoring the building's geometry and soil surface, etc.);
3. Timely implementation of protective engineering measures, such as installing drainage and stormwater systems to effectively divert groundwater, strengthening the soil, and other measures to enhance the stiffness of the soil mass.

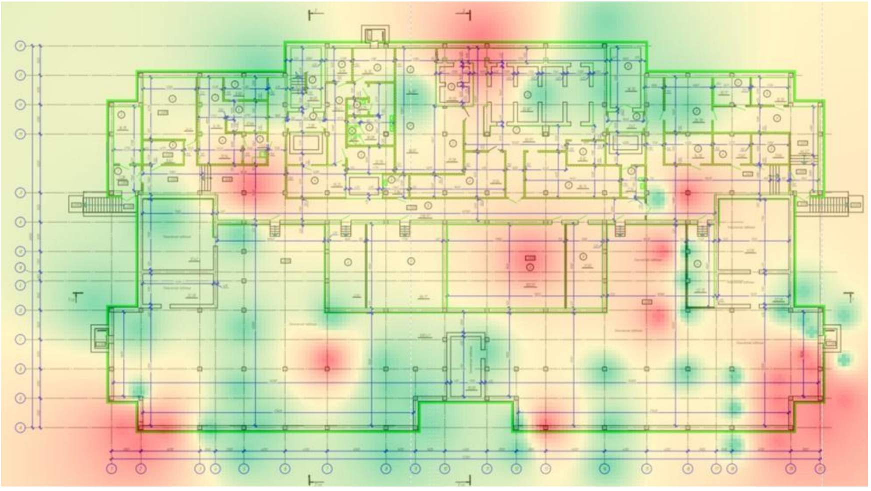

Figure 3: *Zoning of the Soil Mass Beneath the Building Based on Bearing Capacity. In Red Zones, Soil Stiffness Reduction Can Reach Up to 50%*

IV. Discussion

The dynamic-geophysical comprehensive monitoring technology for the "soil-structure" system can ensure the timely detection of geological hazards and assess the potential probability of catastrophic building and structure failures. At the investigation and design stages, it enables the selection of rational engineering measures to enhance the stability of "soil-structure" systems, and during the operational stage, it allows for the control of the effectiveness of these measures.[7]

Abstract

Taking into account the importance of quick detection of oil leaks from submarine pipelines in sea conditions, and the importance of eliminating their consequences, the issues of diagnostics for the determination of leaks and oil losses are discussed in the article. The possibility of determining the location of the leak depending on the degree of leakage is shown. Since the diameter of the pipeline and the physico-chemical properties of oil are assumed in the calculations, the development and application of the mentioned method for the purpose of detecting leaks in specific subsea oil pipelines operated in practice does not require additional costs, as it is based on a known software set and field data.

Keywords: Caspian Sea, subsea pipelines, leak, flow rate, pressure

I. Introduction

One of the factors affecting the ecological environment of the Caspian Sea is the occurrence of oil leaks into the sea as a result of accidents during the operation of offshore pipelines.

Since the products are mainly supplied under wellhead pressure to the subsea pipelines used for the collection and transportation of well products from offshore fields, it is inevitable that new wells start up, stop working, and change their operating modes due to operational challenges. On the other hand, since these pipelines are laid along the bottom of the sea, they are under different hydrostatic pressure depending on the water depth. In deep water basins, it is also possible that this pressure exceeds the working pressure of the pipelines. In such cases, if the subsea pipeline is damaged or punctured, oil will not leak into the sea, but seawater will be absorbed into the pipeline. Once leaks are confirmed, an important issue that arises is the location of leaks and the assessment of oil losses. Detection of small oil spills in marine conditions is associated with many challenges. For the accurate detection and identification of a leak, it is necessary to know the behavior of the fluids inside the pipeline, which allows to determine the pressure drop along the pipeline and the total amount of fluid released, to stop the pumps and control valves to prevent or minimize the damage to the environment [1-4].

II. Methods

Methodology. If we assume that the pipeline is laid along the bottom of the sea with a depth Hd and the internal pressure Px at the point of leakage, the amount of oil flowing into the environment (q) and the condition of oil flowing into the sea can be determined according to the following expressions:

$$q = c_0 \cdot a\sqrt{\frac{2(P_x - P_e}{\rho_n}} \quad (1)$$

$$X_{l.l} < \frac{\left(\frac{P_1}{P_e}-1\right)H_d}{\frac{\rho_o}{\rho_w}\cdot K\cdot Q_1^{2-m}} \quad (2)$$

where: $P_e = \rho_w g H_d$ - hydrostatic pressure exerted by seawater; c0-flowrate factor for the stream (for calculation c0=0.61 can be accepted); a-area of the leakage location (m2); ϱo - oil density (kq/m3); Xl.l - distance to the location of the oil spill; P1 - pressure at the beginning of the pipeline; Q1 - flowrate of oil in the pipeline after the occurrence of a leak; m və k - are indicators that characterize the oil flow regimes in the pipeline.

As can be seen from statement 1, in order to determine the amount of leaking oil, the pressure inside the pipe at the location of the leak must be known.

The pressure inside the pipe at the point of leakage can be determined as follows, depending on the inlet pressure of the pipeline:

$$P_{\tilde{o}} = P_1 - K\cdot\rho_o g Q_1^{2-m}\cdot X_{l.l} \quad (3)$$

If we consider expression 3 in 1, we get:

$$q = c_0\cdot a\sqrt{\frac{2}{\rho_o}\left(P_1 - K\cdot\rho_o\cdot gQ_1^{2-m}\cdot X - P_e\right)} \quad (4)$$

Since the difference between the oil flow rate at the inlet and the outlet of pipeline is taken equal to the oil loss due to leakage, it can be assumed that the leakage amount (q) is known. Then from expression 4 we obtain the following expression to determine the location of the oil leak:

$$X_{l.l} = \frac{\left(\frac{P_1}{P_e}-1\right)H_d}{\frac{\rho_o}{\rho_w}\cdot K\cdot Q_1^{2-m}} - \frac{q^2}{2c_0 a^2 K\cdot gQ_1^{2-m}} \quad (5)$$

Thus, as it can be seen from the statement (5), if a leak has occurred in the subsea oil pipeline, the location of the leak can be determined based on the parameters q, P1/Pe and Q1, taking into account the flow regime and the depth of the sea.

In order to diagnose various cases of oil leakage in submarine oil pipelines, calculations were made for oil with density kg/m3 and viscosity ν = 5*10-6 m2/s in different flow regimes based on expression (5). In order to correspond to real situations, the calculations are based on the depths of the sea Hd = 10, 30, 50, 100, 150, 200, 250 m, the initial pressure in the pipelines P1=1.0-6.0 MPa, and the flow rate Q=0.1-0.8 m3/s. performed for pipelines. The location of leakage (Xl.l) was determined for values of q=1,2,3,4,5,6,7% of different leakage cases. Based on the results of the calculations, the dependences between the Xl.l, Q1 and P1/Pe parameters in 3-dimensional space were graphically depicted in the Delphi environment using a special program for Windows. Those images are shown in Fig. 1 and 2, respectively, for values of q=1 and 7% of leakage cases in Xl.l - Q - P1/Pe coordinate system.

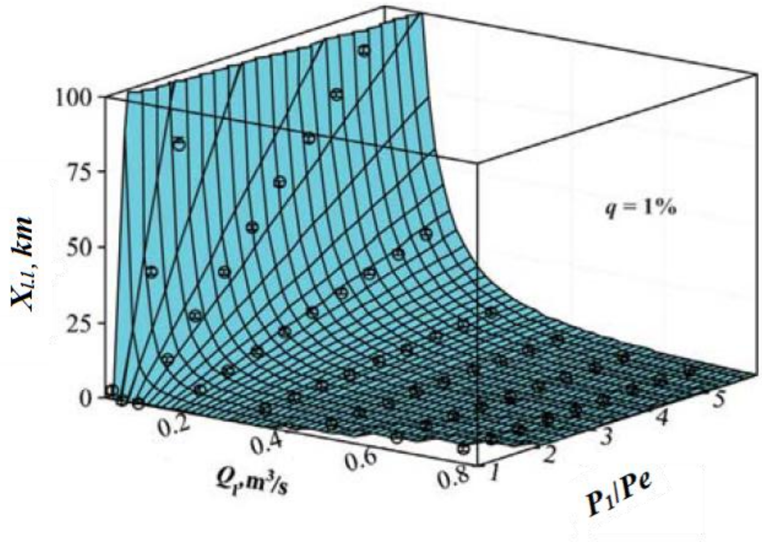

Figure 1: *Dependence of the distance to the leak point in subsea pipelines on the flowrate and pressure ratio (q=1%)*

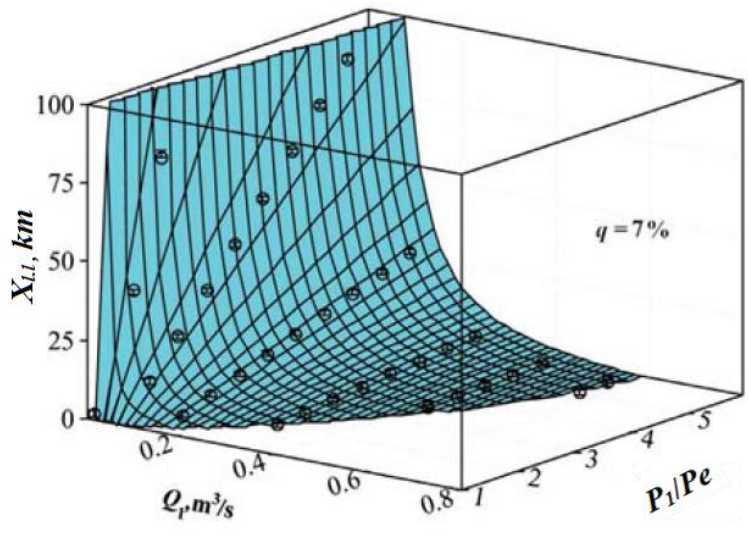

Figure 2: *Dependence of the distance to the leak point in subsea pipelines on the flowrate and pressure ratio (q=7%)*

It was determined that the location of the leak can be indirectly determined with an accuracy of up to 1%, depending on the Q1 and P1/Pe parameters, based on the following regression equation-empirical expression with a very high correlation coefficient (R2=0.999):

$$X_{1.1} = a + \frac{b}{Q_1} + c\frac{P_1}{P_e} + \frac{d}{Q_1^2} + e\left(\frac{P_1}{P_e}\right)^2 + f\frac{P_1}{Q_1 P_e} + \frac{g}{Q_1^3} + h\left(\frac{P_1}{P_e}\right)^3 + \frac{i}{Q_1}\left(\frac{P_1}{P_e}\right)^2 + \frac{j}{Q_1^2}\left(\frac{P_1}{P_e}\right) \quad (6)$$

Here, a, b, c, d, e, f, g, h, i, j are coefficients and are determined by the depth of the sea, the amount of leaks and the flow regimes of oil (Table 1).

IV. Discussion

According to expression 6, in order to determine the locations of oil leaks from subsea pipelines based on the values of Q1 and parameters as soon as the fact of leakage is confirmed, the coefficients included in that expression should be selected according to the known depth of the sea and the accepted leakage rate, and then appropriate calculations should be made. It should be noted that the proposed diagnostic method is not universal and should not be applied to all pipelines. Since the diameter of the pipeline and the physico-chemical properties of oil are assumed in the calculations, the development and application of the mentioned method for the purpose of detecting leaks in specific subsea oil pipelines operated in practice does not require additional costs, as it is based on a known software set and field data.

Abstract

The aim of the work is to obtain composite materials on the basis of pine needles and investigation the properties of composite materials: water absorption, physical-mechanical investigations: (hardness, flexural and stretching and thermal properties, Vicat, FTIR, SEM, energy dispersive X-ray microanalysis and optical microscopic studies. Study of resistance of composites to microorganisms. The pine is one of the more extensively used types of wood used as lumber. The composites were prepared by hot pressing of highly dispersed (20-30 μm) dry pine needles sawdust with triethoxysilylated styrene (in the presence of 1% benzoyl peroxide).Fourier transform infrared spectroscopy (FTIR) confirmed the composition of composites. Optical microscopic examinations showed amorphous clusters on the micrographs, and concentration heterogeneity is also observed. Mostly obtained composites are anisotropic and are characterized by the fibrous structure of supramolecular structures.The surface morphology of the composites was studied by scanning electron microscopy (SEM).

I. Introduction

Agro-industrial waste removal is a serious issue of concerning in developing countries. Cellulose is a polysaccharide polymer. This present review [1] explores cellulose history, structure, worldwide production, and extraction of cellulose from agro-waste. A wide spectrum of researches in the arena of properties of cellulose, hemicellulose and lignin; their degradation; sources and composition of cellulosic and its derivatives from agro-industrial wastes; present status of converting them into value-added products of food and pharmaceutical applications. Cellulose is a tremendous product due to its abundance and characteristic structural properties. The major industrial source of cellulose is vascular plants. The lignocellulosic materials, especially agro-industrial residues, are important as reinforcement products for building construction material industry, in terms of environmental preferences of the modern society. Most paper products generate from wood pulp, while textile fibers are commonly not isolated from woody fibers. The materials based on cellulose and its derivatives have been used for a wide variety of applications, such as food additives, paper manufacturing, pharmaceuticals, or other chemical engineering uses, such as chromatography, paints, and explosives.

Waste is defined as any material, which has not yet been fully utilized, i.e., the leftovers from production and utilization. The waste contains three main constituents: Cellulose, hemicellulose, and lignin, and it can contain various compounds [2]. Cellulose and hemicellulose are carbohydrates that can be broken down by enzymes and acids and then fermented to produce ethanol renewable electricity, fuels, and biomass-based products [3, 4]. However, waste is an expensive and generally unavoidable result of human activity. It includes plant materials, agricultural, industrial and municipal wastes, and residues [5]. Food processing wastes food in spillage, spoilage, discarding substandard edible materials, or removing edible food parts in inefficient processing [6]. Waste significantly impacts environmental, economic, and community health [7]. Plants produce about 180 billion tons of cellulose manufacture annually, and it is the largest reservoir of organic carbon on the earth. Cellulose constitutes the most abundant, renewable polymer resource available today worldwide. It has been expected that by photosynthesis, 10^{12} tons are synthesized annually in a rather pure form, for example, in the seed hairs of the cotton plant but mostly are common with lignin and other polysaccharides in the cell wall of woody plants. Cellulose is the structural part of the primary cell wall of green plants, many forms of algae, and the oomycetes. Cellulose is the most common organic compound on the earth. About 33% of all plant material is cellulose (cotton is 90% and wood is 40–50%). For industrial use, cellulose is mainly obtained from wood pulp and cotton. It is mainly used to manufacture paperboard and paper [8] and it is transformed into a wide variety of derivative products such as cellophane and rayon. Converting cellulose from energy crops into biofuels such as cellulosic ethanol is under exploration as an alternative fuel source.

In recent years great interest in the development of new composites is derived from thermoplastic polymer matrices reinforced with wood filler, because of their environmental and economic benefits [1, 2]. Their renewability, biodegradability, low density, high stiffness and relatively low price are established [3]. Among of these various thermoplastic matrices mainly used in the manufacture of plastic / wood composites was polystyrene [4], which is very popular because of its inapparency, fluidity and good electrical insulating properties [5].

The use of lignocellulosic fibers has certain disadvantages such as degradation at low temperatures with poor compatibility between the polar lignocellulose filler and the non-polar polymer matrix [6]. Due to the strong intermolecular hydrogen bonding between the lignocellulose fibbers, which tend to agglomerate during mixing with the polymer matrix in the compounding process, resulting composites with low mechanical and thermal properties [7].

The improving of the interface compatibility between thermoplastic polymers and lignocellulosic filler has attracted much attention from researchers [8]. Several modifications of the fiber surface such as reaction with acid compounds [9, 10], alkali treatment [11, 12] and the incorporation of compatibilizer, such as malleated polymer [13, 14] or treatment with coupling agents [15, 16] are reported in the literature.

Among the different coupling agents, functional organosilanes [$RSi(OR')_3$)] are often used. These bifunctional molecules with their alkoxylsilane groups are used to modify the surfaces of natural fibers. After hydrolysis reactions of the fibers, surfaces rich in OH groups can be created. Chemical bonds on the surfaces of the fibers through a siloxane bridges, organofunctional groups bond to the polymer matrix. These groups improve the compatibilization between the fibers and the polymer matrix by formation of covalent bonds. The silane coupling agents provide bridges between the fibers and the matrix [17-19].

II. Experimental part

Processing. The composites were prepared by hot pressing of highly dispersed (50 μm) components under pressures up to 15 MPa and temperatures up to 100^0C in molds for 15 min. We have created two types of samples: cylindrical (for investigation of water absorption) and rectangular (for mechanical testing).

Fourier transform infrared spectra were determined with a Varian 660-IR FT-IR Spectrometer. The KBr pellets of samples were prepared by mixing (1.5–2.0) mg of samples, finely grounded, with 200 mg KBr (FTIR grade) in a vibratory ball mixer for 20 s.

Microstructure of the samples was studied by NMM-800RF/TRF type of optical microscope SEM and EDS observations were conducted. Measurements were performed under a microscope - Tescan Vega 3, LMU, LaB 6 cathode. Maximum accelerating voltage was 30 kV, resolution 2.0 nm. The microscope was also equipped with an energy dispersive spectrometer of X-ray-induced electron beam specimens (EDS, Oxford Systems). EDS was used to analyze the sample compositions.

Bending testing also known as flexural testing, was performed on parallelepipeds with the length of 10 cm and the vertical square cross-section of 1 cm^2. Each specimen was placed on two prisms, with the distance of 8.0 cm between the prisms. The indenter was a metal cylinder with the diameter of 10 mm applied from above to the midpoint of the specimen. Bending strength (or flexural strength) is defined as the stress needed to create a breaking point (a crack) in the outer surface of the test specimen .

Impact viscosity determination, also called *shock viscosity* determination, is a technique applied to soft solids and is essentially a drop impact test. The drop height h is the vertical distance between the upper surface of the tested material (h_1) and the bottom surface of the drop hammer at the end of the impact event (h_2). With the sample mass m and the acceleration g, the work performed by the falling hammer is mg ($h_1 – h_2$), anormalized with respect to the horizontal cross-section of the specimen.

Vicat softening depth consists in the determination of the depth of the indentation with respect to the top surface caused by a flat ended indenter with the cross-section of 1 mm^2. The load applied is 10 or 50 N and the cross-section of the indenter end is circular. The term *Vicat hardness* is also in use – really confusing since larger values correspond to lower hardness.

Water absorption is determined simply as the percentage weight change of the sample after submersion in water. We have performed such measurements after 3 hours and 24 hours exposition to water.

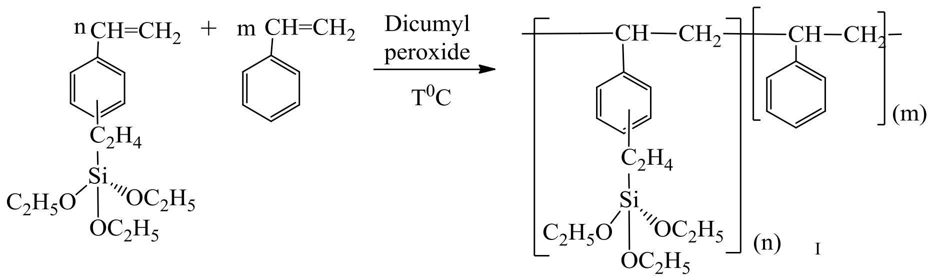
III. Results and discussions

Wood has been an essential material for human survival since the primitive state, for its wide abundance, renewable and environmentally benign nature, relative ease of working it, and outstanding mechanical properties. With the development of technology, wood came to be used for shelter, fuel, tools, boats, vehicles, bridges, furniture, engineering materials, weapons, and even raw materials for energy. Now, wood is widely used in various corners of human life. The wood-polymer composites (WPC) are materials of relatively new generation, in which the role of the binder performs such thermo-plastics polymers as polyethylene, polypropylene, polyvinyl chloride, polystyrene and others. These materials sometimes are called as liquid wood. There are known rather wide assortment of the products made from WPC. Using such methods as extrusion, hot pressing, rotation formatting one obtained such goods as terraces, floor desks, wall panels, roofs coatings, pipes and so on. WPC are distinguished from analogs by high stability to atmospheric influences, mechanical and chemical sustainability, water proofing, which allows to use these materials as coatings of washing rooms, sauna, terraces, and docks and so on. Wood-polymer composites (WPC) are substances or items made up of one or more natural materials or flours but one or a mixture of polymers, such as polyamide, rayon, or latex. Their cheap and superior efficiency, as well as their elevated sustainable development, low moisture absorption, sturdiness against ecological impact such as insects and fungi when compared to timber, high-dimensional data stability over their entire life, and high relative stiffness, have attracted the attention of manufacturers and researchers in recent decades [5].Introduction inorganic nanoparticles have found numerous applications in fields such as medicine, design of electronic devices, catalysis, and polymers reinforcement. Grafting polymer chains endow them with unique functional properties and allow tailoring of their surface characteristics to obtain materials with novel properties and applications. The wood polymer composite on the basis of triethoxy (vinylphenethyl) silane and sawdust via in-situ polymerization has been obtained earlier. The aim of the work was to obtain and research new environmentally safe wood polymer composites (WPC) - based on a new environmentally safe binder and reinforcing agent triethoxy- (vinylphenethyl) silane and styrene and in the presence of antioxidant aluminum hydroxide, study physical-mechanical, thermal properties, and water absorption.

Composites based on dry sawdust on the basis of pine with triethoxy (vinylphenethyl) silane and styrene as a binder and reinforcement agent which was obtained via hydrosilylation reaction of divinylbenzene with triethoxyvinylsilane according to the have been created.The pine is one of the more extensively used types of wood used as lumber**.** The composites were prepared by hot pressing of highly dispersed (20-30 μm) dry sawdust on the basis of pine with agent. The composites have been created under pressures up to 15 MPa and in the temperature range 140-220^{0}C in samples for 5 min. Two types of samples have been created: cylindrical (for investigation of water absorption) and rectangular (for mechanical testing).

It is known that the wood sawdust contains cellulose, hemicellulose derivatives, and lignin structural rings with hydroxyl groups. In our binder triethoxy(vinylphenylethyl) silane we also have ethoxyl groups as well as a vinyl group. Those groups were expected to participate in the etherification reaction with a binder through inter-molecular and intra-molecular reactions and the vinyl group may polymerize. So, used a coupling agent.

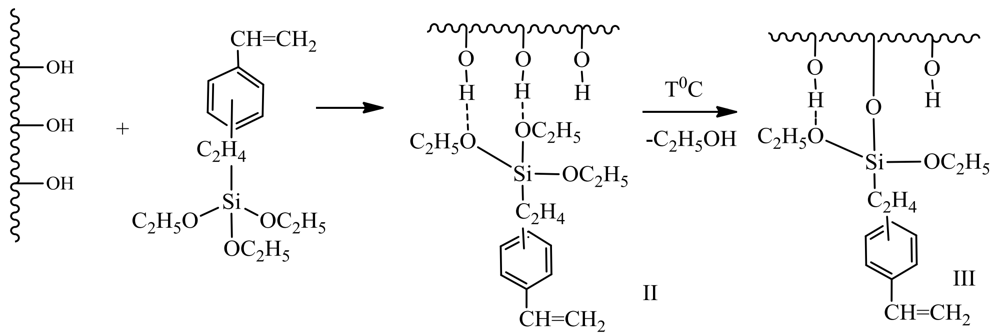
Composites were prepared in the following ratio: 3% triethoxy(vinylphenylthyl)silane, 27% styrene, and dicumyl peroxide, 60% pine sawdust. As filler two types of wood sawdust have been obtained sifted sawdust medium size particle 0.614 mm and unsifted sawdust particle size 1.615 mm The triethoxy(vinylphenethyl)silane (TEVPES) and styrene were stirred with dicumyl peroxide (DP) (1% by weight) and this homogeneous mixture (3-5% (TEVPES) - 27-25 %) was added to a predefined weight ratio of pine sawdust. Then the mixture was stirred for 5 minutes until it became homogeneous, placed in a press form, and pressed at several temperatures. During hot-pressing, the initiator existing in the mixture may initiate the polymerization reaction of vinyl groups of TEVPES and styrene. Wood sawdust impregnated with TEVPES and styrene, at the moment of hot pressing, forms chemical bonds with the hydroxyl groups of a wood surface. Active filler is likely formed, then etherification and in-situ polymerization reactions take place. In the case of dicumyl peroxide during hot pressing, in situ polymerization and copolymerization by the formation of different ring polymers (Structure I) is possible according to the following Scheme 1:



Scheme 1: *Co-polymerization of triethoxy(vinylphenethyl)silane and styrene*

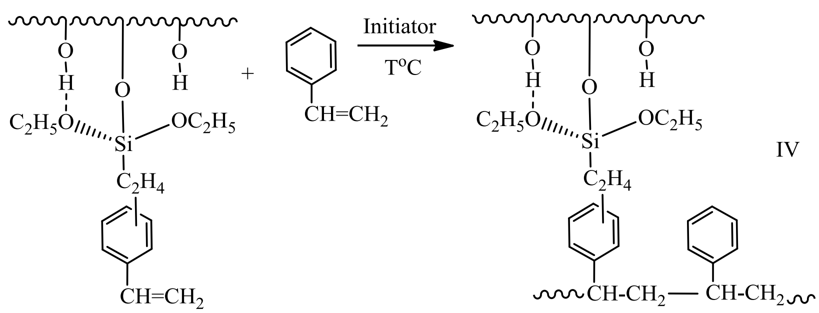
It is not excluded that triethoxy(vinylphenethyl)silane can form hydrogen bonds with or after the polymerization reaction with silane sawdust (Structure II) by etherification at high temperatures to form a chemical bond (Structure III) according to Scheme 2:

In particular, one expects the formation of hydrogen bonds before the onset of the etherification reaction with triethoxysilylated styrene and also the formation of ethyl alcohol.



Scheme 2: *Formation hydrogen bonds and etherification reactions of triethoxy(vinylphenethyl)silane with sawdust surface.*

It is possible that the product of the interaction of triethoxy(vinylphenethyl)silane with cellulose will undergo a polymerization reaction with styrene (Structure IV) according to Scheme 3:



Scheme 3: *Co-polymerization reaction of TEVPES and cellulose interaction product II with* styrene

For obtaining composite materials were performed Fourier transform infrared spectra investigation, likewise, optical microscopic examinations, scanning electron microscopy and energy dispersive X-ray spectral analysis.

In the FTIR spectra of composite materials, one can see the adsorption bands for the asymmetric valence oscillations characteristic of the ≡Si-O-Si≡ bond, up to a maximum of 1026 cm^{-1}, corresponding to siloxane bonds. The absorption band at 1150 cm^{-1} area corresponds to the asymmetric absorption bands characteristic of the Si-O-C and C-O-C bonds, where the absorption bands overlap. Absorption bands at 1262, 1370, 1419, 1507, 1600-1650, 1720, 2800-2950, and 3346 cm^{-1} correspond to the methyl groups, CH bond absorption in (-C / C- /CH_3), CH_2 cellulose - lignin, C=C aromatic, C=C alkene, (C=O ester bonds), phenyl groups and -OH groups.

Mostly obtained composites are anisotropic with different sizes of particles. Cracks and dividing lines are also observed. Whose dimensions can be easily determined using the scale bar.

The surface morphology of the composites was studied by scanning electron microscopy (SEM). In Fig. 1 one can observe indicate pores, indentations, and inserts with the sizes in the range of 0.01-0.5 mm.

For composites, physical-mechanical investigations have been performed. In particular, the determination of the bending strength and impact viscosity with respect to temperature and triethoxy(vinylphenethyl)slane and styrene concentrations has been studied.

As have shown investigation results, with increasing temperature from 140 to 220^{o} C, at 20-degree intervals, the values of bending strength decrease from 10.6 up to 20.9 MPa. With an increase in the TEVPES concentration the values of bending strength increase from 23.6 up to 29.6 MPa. With an increase in temperature, the impact viscosity slightly increases.

The thermal properties of composites have been studied via the Vicat method. The Vicat softening temperature is the temperature at which a flat-ended needle penetrates the specimen to the depth of 1 mm under a specific load. The temperature reflects the point of softening to be expected when a material is used in an elevated temperature application.

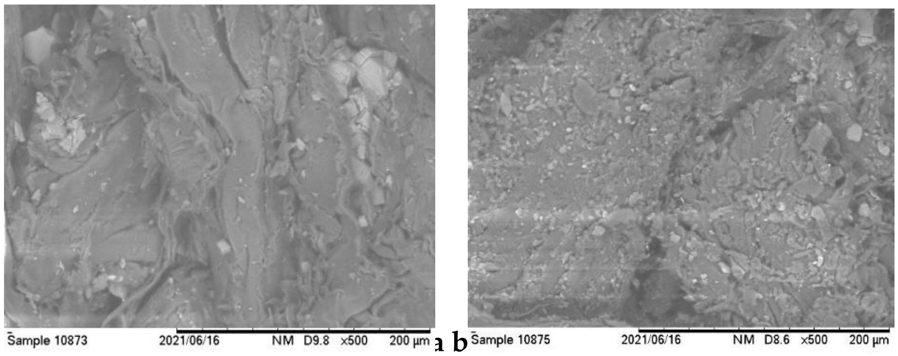


Figure 1: *Scanning electron microscope micrograph of a composites: Sawdust (sifted)-60%+TEVPES -5%+ St -25% +Al(OH)₃ -10%, 160 ⁰C (a), Sawdust (sifted) 60%+TEVPES-5%+ St -25% +Al(OH)₃ -10% (220⁰C) (b).*

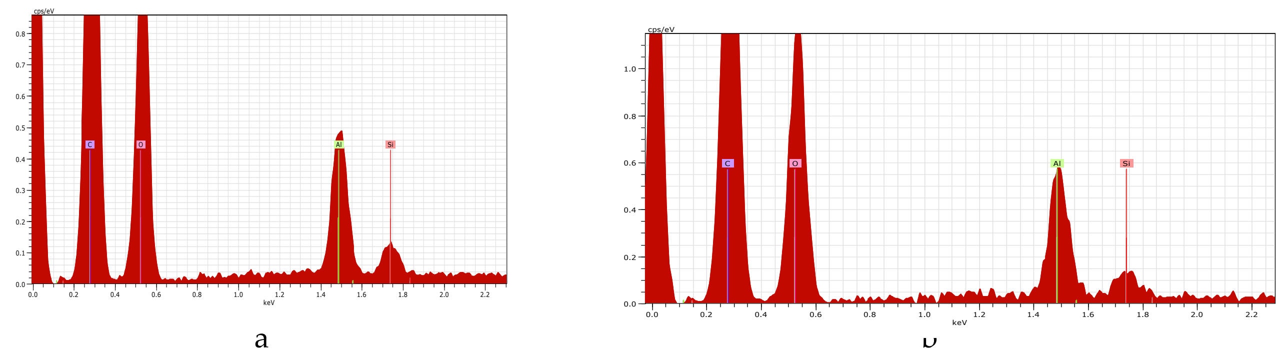

Figure 2: *Energy dispersive X-ray microanalysis of composites: Sawdust (sifted)-60%+TEVPES -5%+ St -25% +Al(OH)₃ -10%, 160 ⁰C (a), Sawdust (sifted) 60%+TEVPES-5%+ St -25% +Al(OH)₃ -10% (220⁰C) (b).*

The composites based on TEVPES, styrene, and Al $(OH)_3$ with sawdust are characterized by improved thermal stability with increasing temperature. This result is expected for two reasons. The total volume of connected empty micro spaces distributed randomly in the composite has been reduced by the pressure application. Consequently, the rigidity and thermal stability of the WPC material increase, and the density of micro-structure increases again TEVPES creates new heterogeneous chemical bonds in the composites via etherification reaction at high temperatures not only with sawdust surface but with used antioxidant Al $(OH)_3$. In parallel, TEVPES reinforce composite materials, by in–situ copolymerization reactions with styrene. The higher this pressure, the higher is thermal stability compositions.

Water-absorption test is a test to determine the moisture content of the soil as a percentage of its dry weight Water absorption is one of the significant magnitudes used to determine the amount of water absorbed under specified conditions.

The results of investigations were shown, that with an increase in pressing temperature from 140^o up to 220^{o}C the water absorption decreases from 54-60% up to 0.95-1.07 %. It must be noted that the WPC obtained from sifted sawdust is characterized by less water absorption. WPC prepared from unsifted sawdust is characterized by increased density compared with sifted sawdust. Both phenomena may be explained with relatively low values in the last column show low volumes of the empty intermolecular spaces.

During the current study composition of composite materials, as well of composition plant materials, used for the preparation of these materials were determined. Specifically, content of Calcium, Magnesium, Sulfur and Silicon were determined. Quantitative analysis were performed using ISO methods. Experimental results comply with theoretically expected results.

SUSTAINABLE DEVELOPMENT OF RURAL AREAS IN SIBERIA IN THE CONTEXT OF GLOBAL CLIMATE CHANGE

Marina Petukhova
•
Novosibirsk State Agricultural University, RUSSIA
petuhova_ms@nsau.edu.ru

Abstract

The article is devoted to determining the prospects for long-term development of rural areas of the Siberian Federal District in the context of global climate change. The study is based on the predicted calculation of changes in hydrothermal conditions within the boundaries of natural and climatic zones of Siberia. It was revealed that by 2050 the predicted shift of natural and climatic zones will be on average 50-100 km depending on the region in the direction from south to north. In some regions (Krasnoyarsk Krai, Novosibirsk, Tomsk and Kemerovo Oblasts) by 2050 there will be a significant improvement in natural and climatic conditions that have a favorable effect on agriculture. Scenarios for the long-term development of rural areas of the Siberian Federal District in the context of global climate change have been developed: "Climate Adaptation", "Climate Mitigation" and "Climate Crisis". Sustainable development of rural areas in Siberia is possible within the framework of the "Climate Mitigation" scenario, which implies mitigating the risks of global climate change through the development of fallow lands, agroforestry, crop rotation, organic farming, etc.

Keywords: rural areas, global climate change, scenarios, climate adaptation, climate mitigation, climate crisis

I. Introduction

Modern challenges affecting the issues of global climate change and its predicted impact both on the agro-industrial complex (hereinafter referred to as the AIC) and on the rural areas that provide it, require the formation of an adequate technological, social and economic response now. That is, this problem can be considered exclusively in the context of the paradigm of sustainable development, which combines these three areas. It is a comprehensive response, implying the development and implementation of innovative AIC technologies adapted to climate change, the creation of new types of organizational forms of rural settlements, the emergence of new types of rural employment, and ultimately the likely expansion of the geography of settlement of the rural population to the north of Russia, that will reduce the risks of global climate change for the AIC and rural areas. This issue is especially relevant for the rural areas of the Siberian Federal District, which are located above the 55th parallel, where, according to climatologists, the greatest consequences of climate change will be observed.

The purpose of this study is to identify promising areas for the sustainable development of rural areas of the Siberian Federal District in the context of global climate change.

II. Methods

The following methods were used as the methodological basis for the study: methods of analysis and synthesis, scenario forecasting, calculation and design and cartographic methods.

The territory of the study is the Siberian Federal District (SFD), which includes 10 subjects (the Altai Republic, the Republic of Tyva, the Republic of Khakassia, Altai Krai, Krasnoyarsk Krai, Irkutsk, Kemerovo, Novosibirsk, Omsk and Tomsk regions). As part of the study, a predicted change in the boundaries of natural and climatic zones in the SFD by 2050 was constructed based on the calculation of hydrothermal conditions. To assess the change in hydrothermal conditions in the SFD, the Selyaninov hydrothermal coefficient, HTC [1], was used, which is currently widely used in the practice of Roshydromet as the main quantitative indicator of the ratio of heat and moisture. The distribution of HTC is in good agreement with geobotanical zones and, in fact, reflects the differentiation of landscapes. To construct the climate projections of the Selyaninov GTC up to 2050, climate projections of air temperature and precipitation amounts obtained from CMIP6 data (scenarios SSP1-2.6 and SSP5-8.5) and adjusted similarly to [2] were used. Previously developed software modules [3] were used to calculate values for individual years and average long-term values in the reanalysis grid nodes and CMIP6. The result of the modules' work is files in the netCDF format.

III. Results

Previous studies [2,4,5] have shown that there is already a shift in the boundaries of natural and climatic zones in the Siberian Federal District, mainly from south to north. It is less noticeable in the steppe zone of the district and quite obvious in other natural and climatic zones. Depending on the generally accepted socio-economic scenarios of the Intergovernmental Panel on Climate Change (IPCC) - SSP1-2.6 and SSP5-8.5, the shift in boundaries can be from 50 to 150 km by 2050 [6]. It should be taken into account that in this study, the shift in zones is understood as a change in the boundaries of zones with a certain heat and moisture supply (certain values of the HTC). That is, in the next 30 years, favorable climatic conditions will be created for changing the areas of vegetation corresponding to certain natural zones. It is also worth noting that the SSP1-2.6 scenario is a sustainable development scenario, i.e. the most optimistic option (shift by 50-70 km), and the SSP5-8.5 scenario is an unfavorable option, assuming further development of the country's economy on fossil fuels (shift by 100-150 km). Within the framework of the second scenario, according to the Sixth Assessment Report, very high greenhouse gas emissions are predicted: by 2075, CO_2 emissions will triple threefold. Each of the listed SSPs provides a future forecast of greenhouse gas emissions and land use changes in accordance with its baseline. In most cases, development according to the SSP5-8.5 scenario will lead to more rapid changes and the advancement of zone boundaries will occur at a distance twice as large as in the SSP1-2.6 scenario [7, 8].

Figure 1 shows a cartographic representation of the predicted change in the boundaries of natural and climatic zones in the territory of the Siberian Federal District subjects. By 2050, the predicted shift of natural and climatic zones will average 50-100 km, depending on the region. During this period, a statistically significant increase in the duration of periods with average air temperatures above 0, +5, +10 °C is predicted, which will have a positive effect on extending the growing season in most of the district.

In addition, there will be an increase in areas with hydrothermal conditions that characterize steppe and forest-steppe landscapes suitable for agricultural production.

Thus, the shift in natural and climatic zones in the Siberian Federal District will become a key factor in the possible change in the structure and directions of economic activity in rural areas. In some regions (Krasnoyarsk Region, Novosibirsk, Tomsk and Kemerovo Region), by 2050 there will be a significant improvement in natural and climatic conditions that have a favorable effect on agriculture. Here it will be possible to expand the area of crops, including by introducing fallow lands into agricultural circulation and growing new types of crops. At the same time, in the republics of Altai, Khakassia and Tyva, in the Irkutsk Region, an increase in aridity of the territory is predicted, which will lead to a decrease in the share of agriculture in the gross municipal product.

Novosibirsk Region (expansion of the northern boundaries of the zones of provided and excessive moisture up to 100 km, the arid zone in the south of the region - up to 75 km) - expansion of the area under grain and leguminous crops, oilseeds by reducing the area of swamps. Involvement of fallow lands in agricultural circulation, development of organic agriculture. Creation of new eco-settlements.

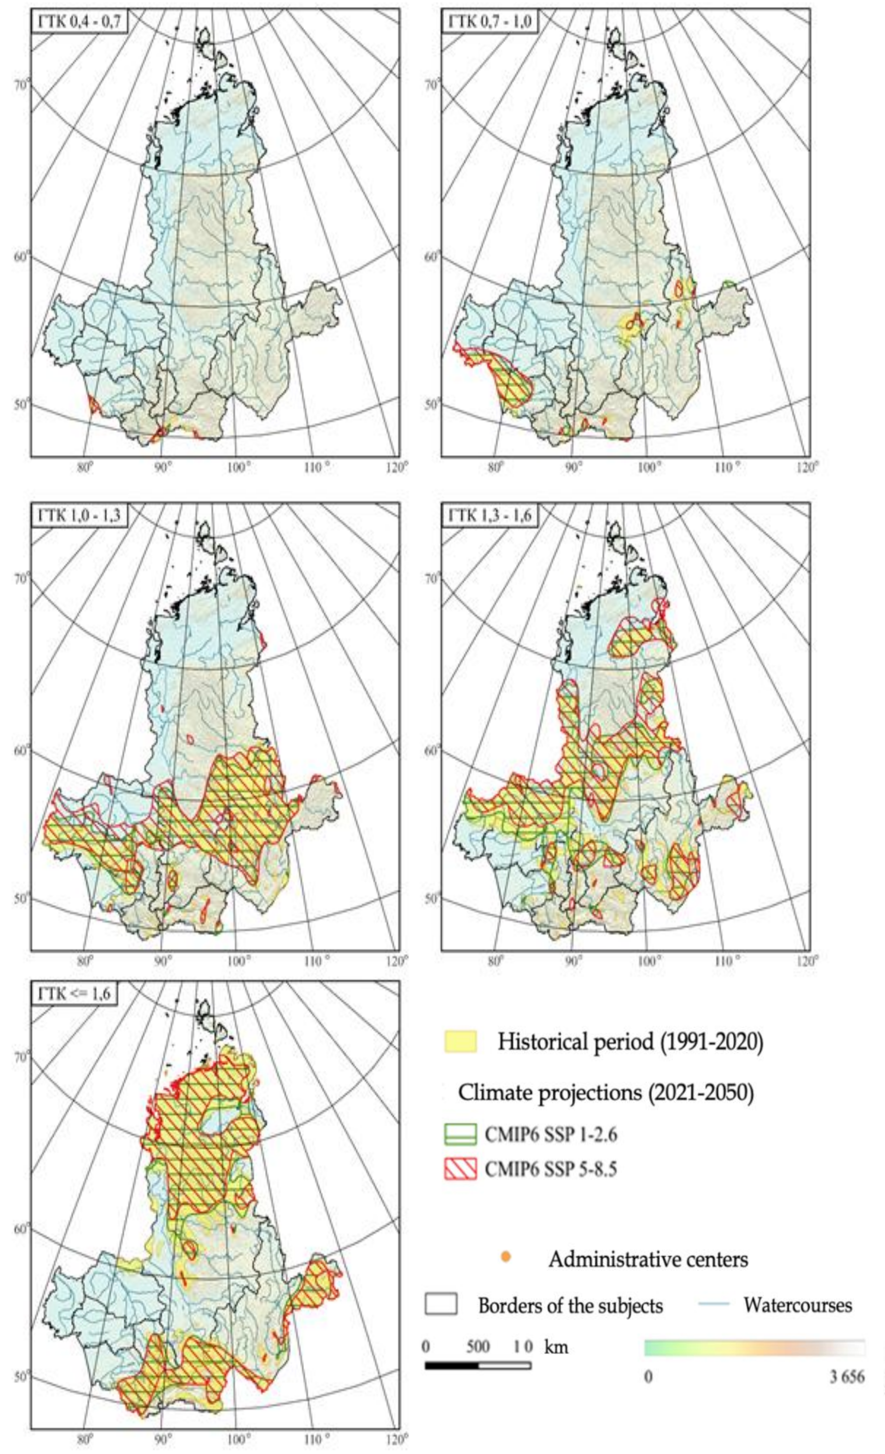

Figure 1: *Forecast zones of humidification by the values of hydrothermal coefficient. Siberian Federal District*

Altai Republic (southeast - semi-desert, shift of the moisture zone to the north) - reduction of sown areas and pastures. Diversification of the rural economy, moving away from agriculture. Development of rural tourism, cultivation of medicinal plants. Development of organic livestock farming. Creation of new eco-settlements.

Krasnoyarsk Region (reduction of the area of excess moisture zones, expansion of the zone of provided moisture. In the east - the appearance of forest-steppe landscapes) - expansion of spring wheat, oilseeds and legumes. Growing winter crops. Possibility of using late-ripening varieties in the south of the region. Creation of new rural settlements and shift camps to provide food for oil production facilities.

Republic of Tyva (predominant zone of excessive waterlogging. Southwest – semi-desert. In the central regions, the zones shift up to 200 km) – strong negative impact of climate change on the rural economy will lead to a reduction in agricultural production.

Republic of Khakassia (no significant natural and climatic changes are observed) – introduction of new areas into agricultural circulation, including fallow lands for organic farming. However, the use of drought-resistant varieties is required due to the increasing aridity of the climate.

Altai Region (expansion of the steppe zone, reduction of the forest-steppe. Shift of zones up to 150 km to the northeast) – cultivation of drought-resistant crops, reduction in grain production. Development of rural tourism.

Omsk Region (decrease in humidity of the territory, with the advancement of zone boundaries to the north) – adverse impact of global warming on the rural economy, reduction in agricultural production. Tomsk Region (shift of excess moisture zone to the north – up to 150 km. The entire territory of the region is an excess moisture zone) – possible increase in crop production due to reduction of swamp areas. Creation of shift camps to provide food for oil production facilities.

Irkutsk Region (increase in the area of arid zones by 40-60 km to the south. In the central regions – over-moistening) – adverse impact of global climate change on crop production. Development of rural tourism.

Kemerovo Region (predominant zones of provided and excess moisture) – diversification of crop production, cultivation of oil crops, development of organic agriculture.

It has been revealed that the natural and climatic zones of Eastern Siberia are "moving north" faster than those of Western Siberia. This is especially true for Krasnoyarsk Region, where as a result of such changes, more and more zones are emerging that are favorable for agricultural production. In this region, the zone of provided moisture is expanding, and new forest-steppe landscapes are appearing. In the Irkutsk Region, opposite trends will be observed: an increase in the area of arid zones in the south and over-moistening in the central part of the region.

IV. Discussion

The study revealed that in the southern regions of the Siberian Federal District (the Republics of Tyva, Khakassia and Altai, Altai Krai), an increase in the average annual temperature leads to a decrease in the yield of grain and leguminous crops, while in more northern regions (Krasnoyarsk Krai, Tomsk and Novosibirsk Oblasts) - on the contrary, to an increase, which is confirmed by the correlation coefficients. The contribution of temperature growth to the change in yield is on average 10-20% [2]. That is, it can be concluded that global warming will have the most favorable effect on the subjects of the Siberian Federal District located in the north of the macroregion. Global warming here will be accompanied by an increase in the growing season, a longer frost-free period, etc. It will be possible to grow new varieties of crops, including late-ripening ones. Improved natural and climatic conditions will allow the introduction of fallow lands into agricultural circulation, which can be used, among other things, for growing organic agricultural products. In the southern regions, the increase in climate aridity will lead to an increase in the number of droughts and, accordingly, a reduction in crop yields. In these regions, it is necessary to use drought-resistant varieties of agricultural crops, introduce pre-sowing seed treatment technologies and apply mineral fertilizers.

The author proposes three scenarios for the long-term development of rural areas in the Siberian Federal District in the context of global climate change: "Climate Adaptation", "Climate Mitigation" and "Climate Crisis". The basic scenario condition for all three scenarios is the shift of natural and climatic zones from the south to the north of the macroregion.

Within the framework of the "Climate Adaptation" scenario, the rural economy will adapt to the predicted natural and climatic changes. It is necessary to use drought-resistant plant varieties, change the timing of agro-technological work, increase the use of mineral fertilizers and chemical plant protection products, and irrigation systems to preserve crops. The main measures to adapt to climate change will be the implementation of hydromelioration and other reclamation measures, coastal protection and clearing of river beds, and the restoration of degraded lands [9].

As a result of the implementation of these measures, the impact of climate change on agricultural production will be minimized (reduction of losses from natural disasters - droughts and floods) [10]. An example of adaptation measures in Russia is the restoration of 7 km of the historical Ural River bed in the Orenburg Region as part of the national project "Ecology".

In regions where the efficiency of agricultural production continues to decline, the rural economy will be reoriented to new sources of growth, as mentioned above. "Climate adaptation" is a basic scenario for the long-term development of rural areas in Siberia, which assumes the extrapolation of existing trends.

The "Climate mitigation" scenario involves the development of measures aimed at eliminating or reducing the long-term risks of climate change. This scenario should be based on sustainable development of agriculture and rural areas, integrating economic growth, social well-being and ecological balance. This is an optimistic option for long-term rural development, implying a reduction in greenhouse gas emissions from agricultural production.

The following natural climate solutions should be implemented within the framework of the "Climate Mitigation" scenario:

1) agroforestry, sanitary felling, optimization of logging operations;

2) accumulation of organic matter in the soil and reduction of soil carbon losses in arable land and meadows;

3) crop rotations;

4) reclamation of degraded lands and reduction of nitrogen losses when applying mineral and organic fertilizers;

5) agrotechnical measures to prevent salinization and soil degradation;

6) cultivation of perennial plants;

7) pasture management.

In addition, "Climate Mitigation" requires the development of measures to significantly reduce forest fires, which is extremely important for the territory of Siberia.

Thus, the condition of this scenario should be the introduction of resource-saving technologies both in agriculture and in land use.

The result of this scenario will be the introduction of new areas of agricultural land into circulation, diversification of agricultural crops, growth in crop yields and animal productivity, and the creation of new rural settlements. For example, in the Altai Territory, the ANO "Center for Environmental Innovations" leased agricultural land in the Zalesovsky District with an area of 10 thousand hectares for 49 years. Where forests were planted to absorb greenhouse gases.

The "Climate Crisis" scenario assumes the absence of any measures on the part of local, regional and federal authorities and the population to adapt and/or mitigate economic activity to natural and climatic changes. This will lead to the extinction of villages and an increased outflow of the rural population to the city. Agriculture, as one of the main sources of income for the rural population, will be exposed to increasingly frequent extreme natural and climatic conditions, which will lead to the loss of sustainability of rural households. The absence of measures to prevent the consequences of global climate change will further accelerate the warming process due to increasing greenhouse gas emissions. "Climate Crisis" is a negative scenario for the long-term future of rural areas of Siberia, threatening Russia's food security. According to the authors, the most optimal direction for long-term development of rural areas of the Siberian Federal District in the context of climate change will be the integration of two scenarios: "Climate Adaptation" and "Climate Mitigation", within the framework of which adaptation measures will be jointly implemented, as well as the prevention and mitigation of the risks of global climate change.

The authors identified the following as key technologies for mitigating rural development to climate change:

1. Agricultural land management, which consists of improving agricultural technologies in terms of increasing crop resistance to unfavorable natural and climatic conditions and pests (biotechnology), precise application of fertilizers and plant protection products, organizing optimal crop rotations, agro-improvement, and introducing methods of minimum crop cultivation (No-Till, Mini-Till).

2. Livestock management as one of the main sources of methane emissions - improving the feed base for farm animals and improving their well-being (keeping conditions and selection). Here, it is necessary to find a balance between reducing the number of animals and increasing their productivity.

3. Management of organic fertilizers/solid biological waste, which is the basis of closed-loop agricultural production, when livestock waste is used as organic fertilizer in crop production.

4. Bioenergy – production of solid, liquid and gaseous fuels for energy supply of agricultural production from grown biomass. Corn, soybeans, sorghum, crop residues, millet, etc. can be used as raw materials for processing.

5. Organic agriculture is a concept that can make the industry carbon neutral. According to estimates, greenhouse gas emissions from the use of mineral fertilizers annually worldwide amount to about 1000 million tons. With organic farming, their use is completely excluded.

The following can be attributed to the technological areas of adaptation of the rural economy to climate change:

1. Development of new technologies and plant varieties resistant to climate change, adapted to the conditions of areas with a difficult climatic situation.

2. Increasing the efficiency of the irrigation and moistening system of crops, including through the rational use of alternative water sources.

3. Intensification of the use of organic methods of raising livestock and poultry, increasing the importance of practices to ensure the welfare of farm animals (better feeding and housing conditions).

4. Expanding and improving measures for the prudent use of natural resources, including measures to preserve highly fertile soils, reduce the amount of degrading land, and eliminate ineffective forest management practices.

5. Training and supporting the rural population in the field of sustainable agriculture and environmental practices, including consultations, trainings, and public educational events.

At the same time, a mandatory condition for the introduction of adaptation technologies should be taking into account the risks to the country's food security; a balance is needed between economic efficiency and the impact on surrounding ecosystems.

Sustainable development of rural areas in Siberia is possible within the framework of the "Climate Mitigation" scenario, which implies mitigating the risks of global climate change through the development of fallow lands, agroforestry, crop rotation, organic agriculture, etc. [11] The implementation of this scenario will create the preconditions for the emergence of new organizational forms of rural settlements in Siberia:

1) eco-settlements - rural settlements whose main activity is organic production of agricultural products;

2) tourist settlements - concentration of various types of rural tourism within one rural settlement;

3) rotational settlements, the purpose of which is to manage remote robotic agricultural production in new territories;

4) water and forest protection settlements - specialized rural settlements implementing mitigation measures for agroforestry and hydromelioration;

5) agrotowns - low-rise settlements of landscape-estate type in places of concentration of agricultural production;

6) smart villages - comfortable settlements with highly developed digital infrastructure.

As the conducted studies have shown, the most favorable region for the creation of new rural settlements may be Krasnoyarsk Krai, where the most rapid change in natural zones is predicted towards an increase in the area of more favorable conditions for agriculture and rural population (steppe and forest-steppe landscapes). In addition, increasing the duration of periods with average air temperatures above 0, +5, +10 °C will create comfortable conditions for the development of various types of tourism in the region.

Abstract

The current study built and characterized modified sorbents and then tested their ability to absorb the waste products in a lab setting. This work investigated the physicochemical properties and structure of enhanced environmentally friendly sorbents based on alginates, bentonite, and nanoparticles using spectroscopic techniques (SEM, FTIR, X-ray diffraction, and XRD analytical methods). Because the alginate core contains active COOH and OH groups, it may be chemically and physically changed and used in a range of phosphate anion adsorption techniques. We determined the sorption efficiency of a modified Fe3O4NPs@AlgBT. Using biofilters to lessen nutrient loading is an easy substitute for this. Thus, in a lab setting, the capacity of the Fe3O4NPs@AlgBT (biosorbent) to absorb nutrients and heavy metals at various starting concentrations and contact times was examined. It has also undergone testing for uses of nutrients other than growth in wastewater. Fe3O4NPs@AlgBT conducted a nutrient uptake experiment that revealed substantial nutrient uptake in all time intervals (7, 13, 19, and 25 hours) sustained at various pH levels (3–11). From all of these, the maximum amount of nutrients removed was demonstrated by 25-hour biosorption at pH 7,5. A pH of 7,5 and 25 hours later showed the maximum zinc absorption, with an ideal in vitro seaweed content of 0.5 g. The enhanced capacity of Fe3O4NPs@AlgBT to absorb nutrients and consequently stimulate development was demonstrated in an experimental investigation conducted using wastewater.

Keywords: alginate, bentonite, nanoparticles, adsorbents, waste products

I. Introduction

The excessive rise in nutrient content in water bodies, particularly in nitrogen and phosphorus, is a result of aquaculture's quick expansion. The standard method for obtaining these nutrients is to fertilize the pond with food and animal metabolic waste from raised animals. Thus, creating ecologically friendly plans that reduce these activities' detrimental effects has been the major problem [1-4]. The most pragmatic and economical method of lowering aquaculture nutrient concentrations is to treat wastewater before to its discharge into the ocean. Biological wastewater treatment with macroalgae for nutrient removal is a possibly workable substitute. It has been stated that heavy metals including Fe, Zn, Ca, and Mg have biological importance in humans and can be taken on a regular basis for medical purposes [5-7]

Even for those of biological importance, food intake must be maintained within regulatory limits, as excess will result in poisoning or toxicity, as evidenced by some reported drug symptoms that are clinically pronounced. Methods for removing metal ions from aqueous solutions mainly consist of physical, chemical and biological technologies. The advantages and disadvantages of traditional metal removal technologies are summarized. In recent years, the application of biotechnology for the control and removal of metal pollution has received much attention and is gradually becoming a hot topic in the world. Areas of metal pollution control due to its potential applications [8-12].

An alternative process is biosorption, which uses various natural materials of biological origin, including bacteria, fungi, yeast, algae, etc. These biosorbents have the property of binding metals and can be used to reduce the concentration of heavy metal ions in solution. It can effectively and quickly isolate dissolved metal ions from dilute complex solutions, so it is an ideal candidate for treating complex wastewaters of large volume and low concentration [13-15].

II. Methods

Preparation of biosorbent - Laminariaceae algae samples from several locations in the Caspian Sea were gathered in order to prepare alginates. The alginate extraction method includes numerous phases. Alginate that is water-soluble is created by first converting the alginic acid ions in the algae into pure alginic acid, which is subsequently reduced by sodium carbonate/hydroxide. In order to recover the soluble alginate, calcium chloride precipitation is used to create calcium alginate, which is then processed with sodium carbonate to create sodium alginate. Bentonite – is obtained from a clay deposit located in the village of Dash Salakhly, Gazakh region of the Republic of Azerbaijan (AzRosPromInvest LLC). This deposit is one of the highest quality natural deposits in the world. Nanoparticles of iron oxide Fe_3O_4 with superparamagnetic properties were obtained by chemical coprecipitation from aqueous solutions of ferrous and ferric salts in an alkaline medium created with NH_4OH in a nitrogen gas atmosphere. Following separation using a permanent NdFeB magnet, the resultant Fe_3O_4 nanoparticles (NPs) were periodically rinsed with distilled water before being disseminated in ethanol. An ethanolic solution of Fe_3O_4 nanoparticles was added to an ethanolic solution of the macro heterocycle taken in excess with vigorous stirring. After stirring for 8 hours at ambient temperature, the resulting nanostructures were isolated by applying a constant magnetic field and washed repeatedly with distilled water [16].

A particular amount of bentonite was dissolved in 30 mL of a 2% (v/v) acetic acid solution for 50 minutes. Addition of 0.03 g of Fe_3O_4 to the bentonite solution and three hours of stirring produced the same mixture. After adding a certain quantity of bentonite clay to the homogenous mixture, the combination was stirred for 60 minutes at 65 °C before alginate was added. The Fe_3O_4@AlBT mixture was, in the end, washed with 100% ethanol and dried at 50 °C in a furnace.

XRD - Using a Rigaku Mini Flex 600 XRD diffractometer at room temperature, XRD (X-ray diffraction) examination was carried out. Cu K α radiation from a Cu X-ray tube operating at 15 mA and 30 kV was utilized in each example. The samples underwent scanning within the 20–70 ° Bragg angle 2 h range.

FT-IR - (FTIR) spectroscopy, were investigated. Using a Varian 3600 FTIR spectrophotometer, FTIR spectra were captured in KBr tablets. At room temperature, the spectra was recorded in the 4000-400 cm^{-1} range.

Analysis using the Energy-Dispersive Spectrum (EDS) and a scanning electron microscope (SEM)- Prepared samples were subjected to SEM and EDS examination using a Field Emission Scanning Electron Microscope (JEOL JSM-7600F) operating in the SEI domain at an accelerating voltage of 15.0 kV [18].

III. Results

Using spectroscopic techniques (SEM, FTIR, X-ray diffraction, and XRD analytical methods), researchers examined the physicochemical characteristics and structure of enhanced ecologically friendly sorbents based on alginates, bentonite, and nanoparticles [17].

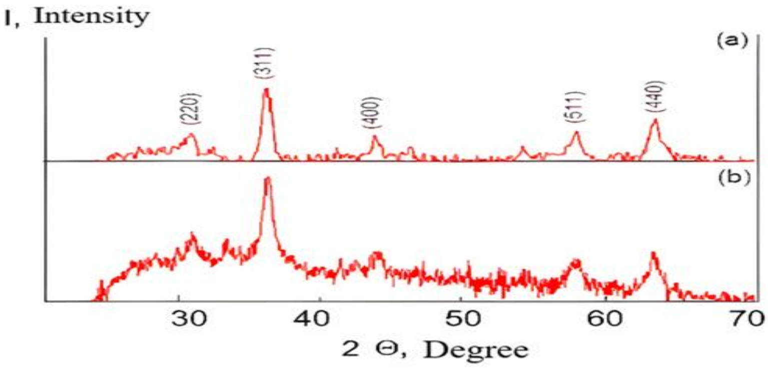

Figure 1: *XRD-Pattern of the obtained nanosized samples*

Data from the X-ray examination of samples of MC@Fe_3O_4 NPs are shown. Visualization of all the diffraction peaks of the acquired samples indicates that they are cubic-shaped Fe_3O_4 nanoparticles.

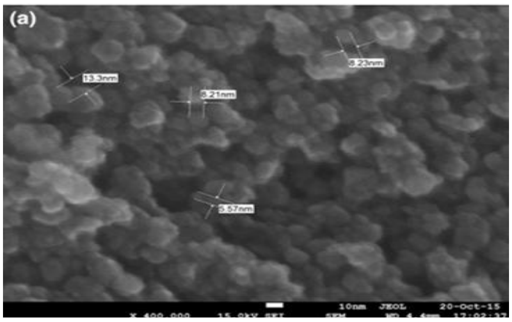

Figure 2: *Scanning electron microscope image of Fe_3O_4 NPs sample*

According to the SEM analysis it was investigated that the resulting nanostructures have a homogeneous structure and they are nanosized.

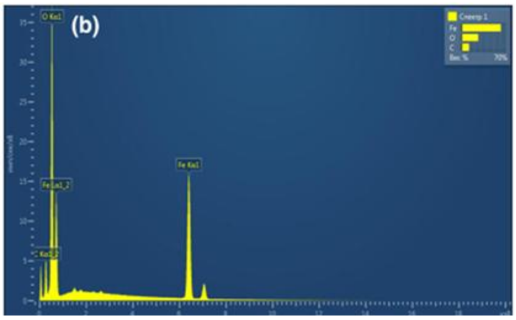

Figure 3: *Electron dispersion spectrum of the Fe_3O_4 NPs sample*

The samples indicate EDS analysis verifies the synthesis of magnetite nanoparticles by identifying Fe and O as the primary components present in the sample composition of the produced nanostructures.

Effect of pH and Time on Nutrient Absorption

In this study, maximum phosphate removal was achieved at pH 7,5, with an initial phosphate concentration of 0.5 μmol/L eventually decreasing to 0.05 μmol/L over 25 hours and a final value of 0.08 μmol/L at pH 7 was the second best (Figure 4).), pH 6 had the lowest phosphate removal at 25 hours at 0.18 μmol/L. Ammonia concentration decreased significantly in the pH range 3-11. The lowest ammonia removal (88.83 μmol/L) was recorded at pH 4 after 12 hours; the highest removal was recorded (67.55 μmol/L) at pH 7,5 and duration 25 h. Nitrate concentrations decreased significantly at pH 3 and 13. The lowest nitrate removal occurred at pH 6 - 0.07 µmol/L, and at pH 11 - 0.06 µmol/L. The greatest nitrate removal was recorded at pH 7,5, where it decreased from 0.07 µmol/L to 0.05 µmol/L. Nitrite concentration decreased markedly at pH 3 and pH 11. A gradual decrease in nitrite concentration was observed at all pH values. The maximum nitrite removal was 4.88 µmol/L at pH 7,5, while the lowest nitrite removal of 28.30 µmol/L was observed at pH 5. From the results presented, it is clear that pH has a significant effect on the reduction of nutrient concentrations . A pH of 7,5 was found to be at which nutrient concentrations were significantly reduced, although significant nutrient removal was also observed at both acidic and basic pH concentrations. Stirring the nutrient solution also improved nutrient adsorption by the seaweed. Similarly, increasing the duration of the experiment was found to enhance the adsorption process. This is evident from the fact that maximum nutrient removal was achieved after 24 hours.

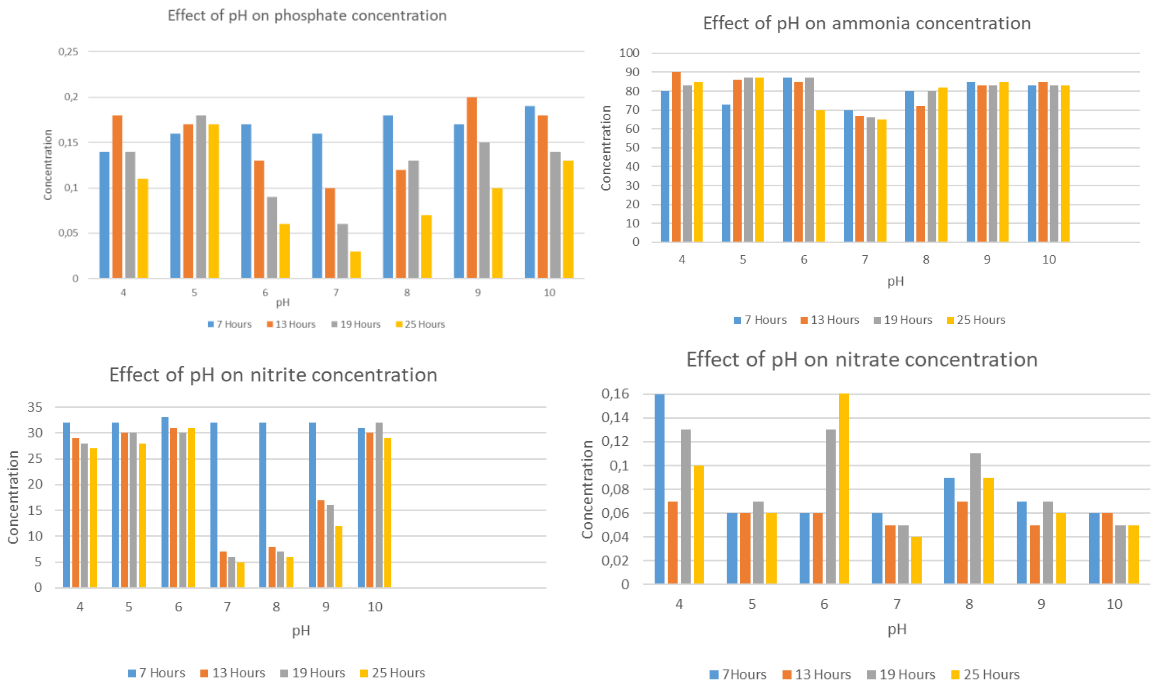

Figure 4: *Effect of pH and time on nutrient removal*

The effect of pH of aqueous solution is a key controlling parameter for the biosorption of heavy metals. pH levels ranging from 3 to 11 have been tested for the uptake of heavy metals by seaweed. The results showed that the removal of heavy metals was directly proportional to pH (Fig. 4). This experiment was carried out at three different concentrations at two different time intervals. The maximum removal (17.4 µg/L) of zinc was observed at a concentration of 0.1 g of seaweed at pH 10 in 24 hours, and the minimum removal (87 µg/L) at pH 6 in 13 hours. At pH 11, maximum zinc removal was achieved at a seaweed concentration of 0.5 g in 24 hours, the zinc concentration was 0.4 µg/L. 0.5 µg/L was the second best maximum zinc removal rate at the same seaweed concentration observed after 13 hours. 1 g concentration of seaweed significantly reduces zinc content. Minimal zinc removal was observed after 13 hours at pH 3 (73.66 µg/L). Maximum zinc removal was observed at pH 11 at 24 hours (3.4 µg/L). Metal uptake increased with increasing pH. A gradual increase in the biosorption of heavy metals was observed as the pH transitioned from acidic to basic. Although heavy metal biosorption was recorded at both acidic and basic pH, heavy metal removal was unsatisfactory under acidic conditions. Thus, it is clear from the present study that pH above neutral conditions is capable of improving the removal of heavy metals. This may be due to the presence of more free binding sites on the biomass that absorb heavy metals from solution at these pH concentrations. In the phenomenon of biosorption, the pH value affects two aspects: the solubility of metal ions and the overall charge of the biosorbent, since protons can be adsorbed or released. This behavior will depend on the functional groups present on the algal cell wall, which in turn determine the acidity constant.

The increase in the level of biosorption with increasing pH can be explained by the influence of the number of negative charges, which depends on the dissociation of functional groups. At low pH values, the concentration of hydrogen protons in the solution significantly exceeds the concentration of zinc ions and, therefore, the protons compete with metal ions to form bonds with active sites (functional groups) on the surface of the algae, leaving metal ions free in the solution. These bound active sites subsequently become saturated and inaccessible to other cations. As pH increased, the competing influence of hydrogen protons decreased.

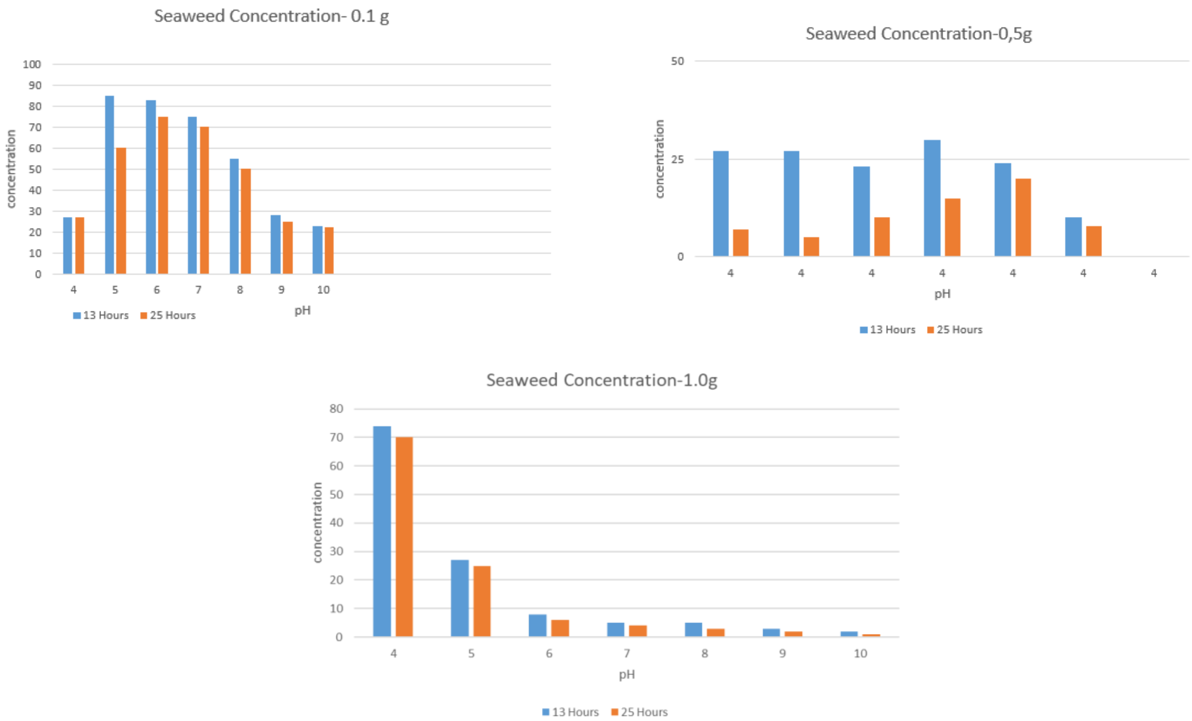

Figure 5: *Effect of pH, time and concentration of seaweed on the adsorption of heavy metals*

Therefore, an increase in sorption capacity or removal efficiency can be observed. Contact time is also rated as one of the most important factors affecting biosorption efficiency. The efficiency of biosorption increases with increasing contact time. As a result of these experiments, it was found that the efficiency of biomass biosorption reaches a maximum after 24 hours.

Biomass concentration is another important variable during metal uptake. The effect of biomass concentration on the biosorption of zinc ions was studied using different dosage ranges (0.1, 0.5 and 1 g), respectively. High concentrations of biomass can have a sheathing effect, protecting active sites from metal occupation. But the uptake of metals can also decrease with increasing biosorbent dosage, which may be due to the complex interaction of several factors. This may be due to partial cell aggregation, which occurs at high biosorbent concentrations and leads to a decrease in the number of active sites; we also observed this trend in our biosorption experiments. It has been suggested that electrostatic interactions between cells may be a significant factor in the relationship between biomass concentration and metal sorption. Because of this, for a given metal concentration, the lower the biomass concentration in the suspension, the higher will be the metal/biosorbent ratio and the metal retained by the sorbent unit until the biomass reaches saturation.

Concentrations of the four nutrients tested

The concentrations of the four nutrients tested (NO_2-N, PO_4-P, NO_3-N, and NH_3-N) decreased significantly during the experimental period indicating that adsorbents have a strong ability to remove nutrients (Figure 6) . PO_4^{3-} concentrations decreased from 0.038 μmol/L to 0.003 μmol/L, corresponding to approximately 95.6% of the nutrients being eliminated over the five days of the study. A significant reduction in NO_3 concentration was observed in the present study. The greatest reduction occurred from the fourth (20.585 μmol/L) to the fifth days (13.392 μmol/L), corresponding to the removal of approximately 49% of nutrients.

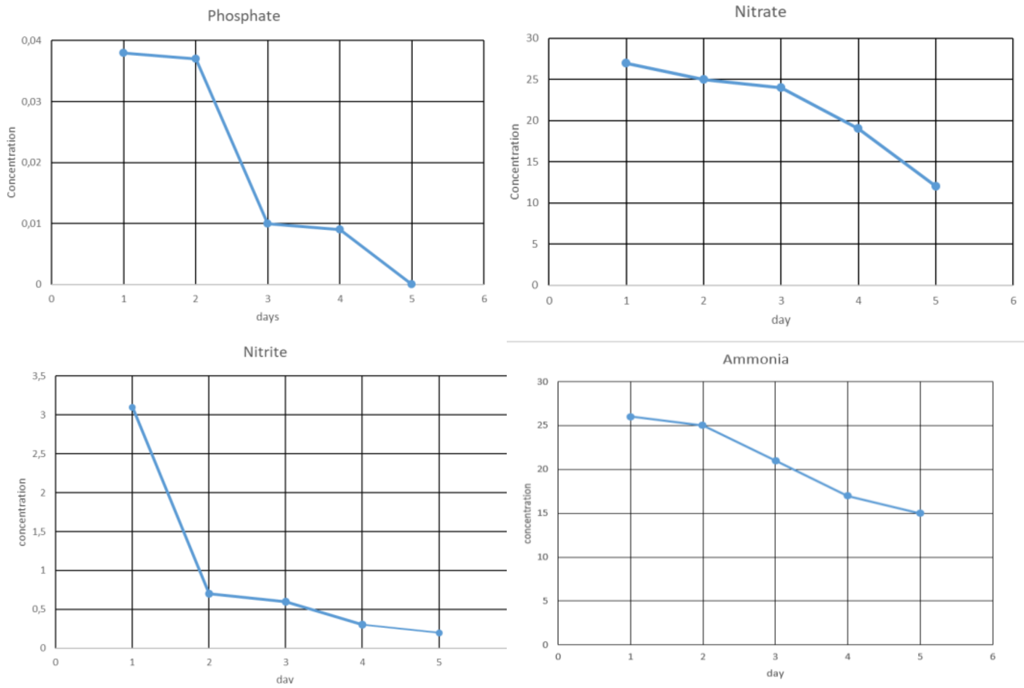

Figure 6: *Rate of removal of nutrients from wastewater*

The nutrient removal capacity for the entire period was approximately 55.55%. At the end of the experiment (fifth day), most of the NO_2 was absorbed, which is consistent. Removal efficiency 93.4%. There was also significant. Removal of NH_3^+ (43%) during the experiment. Significant decrease in NO_3 (13.392 μmol/L) during the culture period. This decrease may be due to the mineralization of organic matter. Previous studies have also shown that seaweed is capable of removing high concentrations of PO_4^{3-}. However, only the studies carried out found higher than in our present study. Removal of NH_4^+ from wastewater by seaweed occurred gradually between the beginning and end of the experiment (27.123–15.976 μmol/L). The biofiltration capacity of NO_3 obtained in this experiment was significantly higher. Because nitrate has a secondary source in nitrification processes. In addition, all other aspects must be taken into account changes in seaweed removal efficiency.

IV. Conclusion

In conclusion, ecologically friendly Fe_3O_4NPs@AlgBT sorbents have been obtained and has huge adsorption capacity in the incorporation of layered double hydroxides and the alginate matrix significantly improved the adsorption capacity of the developed toward water treatment.

The study showed that Fe_3O_4@AlgBT showed significant removal of nutrients and heavy metals. Therefore, it is considered for bioremediation of domestic and industrial wastewater that may cause environmental pollution.

It was concluded that Fe_3O_4@AlgBT can be used as a bioremediant in wastewater treatment plants to preserve nature and natural resources.

In addition, waste from cultivated seaweed can be used as feedstock to produce biofuels, biofertilizers and animal feed additives, reducing the cost of the wastewater treatment process.

Abstract

Adjara is located in a mountainous, exceptionally small region, noted for its diverse and unique natural landscapes. In this area, intense land exploitation disrupts the already delicate balance of the geological environment, leading to the active advancement of natural geological processes. Consequently, the natural regeneration of forest ecosystems following a disaster is understood to be a complex successional process. Over35 years, the regenerated forest ecosystems on the landslide-affected slopes of the valley have been extensively studied. For this research, the systematic arrangement of the flora was analyzed, phytocoenology surveys were conducted, and assessments of soil fertility were completed. The flora of the naturally regenerated vegetation comprises 101 species, which are organized into 32 families and 84 genera. Species-rich families such as Asteraceae, Borraginaceae, Lamiaceae, Poaceae, Brassicaceae, Umbelliferae, Scrophulariaceae, Caryophyllaceae, and Leguminosae are identified. In the research site, as woody plants developed, cenotic relationships gradually emerged among species within the phytocenoses of the pine forest (Pineta; Pinus sosnovskyi), including Pinetum Ramnosum, Alnetum Pinetozum, Alnetum Ramnosum, and Alnetum Salixsosum. Consequently, tiered differentiation occurred, a tree canopy was established, and a specific system for natural regeneration was formed. The chestnut, oak, mixed (polydominant), and beech sub-zones within broad-leaved forests are primarily characterized by typical forest soils. It has been demonstrated through studies that the pH (KCl) of soil samples obtained from regenerated forests is 5.8, indicating a weakly acidic soil reaction. The strong buffering properties of the soil absorption complex are indicated by its high calcium content (336 mg/100g) and magnesium content (43.8 mg/100g). Low levels of total humus and nitrogen content are observed in the soil. The natural forest soil, with a neutral reaction (pH 7.1), is characterized by richness in calcium (378.7 mg/100g) and magnesium (50 mg/100g). Both soils possess a significant reserve of mobile phosphorus and potassium content. In comparison to the regenerated forest soil, the natural forest soil contains 1.65% more humus and 0.132% more total nitrogen. In the vicinity of the surveyed slopes, amid the presence of the derivative-type cascade Skhalta hydroelectric power station, an investigation was conducted on the soil's multi-elemental composition to evaluate the current ecological conditions and identify any toxic elements. Nickel (Ni), mercury (Hg), lithium (Li), antimony (Sb), selenium (Se), thallium (Tl), and vanadium (V) were detected below the detection limit in the 0–40 cm layer of soils. The concentrations of manganese (Mn), cadmium (Cd), lead (Pb), and molybdenum (Mo) in both soil samples exceed the permissible limits. This could be attributed to the proximity of the Skhalta Hydroelectric Power Plant (HPP) to the slopes, where its reservoir is fed by water from the Chirukhi River discharged through the derivation tunnel. Crushed rocks were deposited and spread on the surrounding slopes during the construction of the tunnel, potentially increasing the levels of heavy metals in the soil.

Keywords: secondary ecosystems, forest, variety, soil fertility, multi-element analysis

I. Introduction

Adjara is situated in the Caucasus, a region renowned for its biodiversity and recognized by the International Union for Conservation of Nature (IUCN) as one of the world's 36 biodiversity hotspots. This designation highlights regions with the highest biological diversity and a significant number of endangered terrestrial ecosystems. Additionally, the Adjara floristic region is part of the list of 200 ecoregions globally recognized, located in the southwestern corridor of the Lesser Caucasus. This area is notable for its species richness, high endemism, taxonomic uniqueness, distinctive origins, and rare habitats. Our region is also among the 25 regions worldwide with a uniquely high level of biological diversity, emphasizing the urgent need for its protection.

Adjara, with its diverse natural landscapes, stands out as one of the unique regions in Georgia. This uniqueness arises from its varied natural conditions and the complex history of its flora and vegetation development. According to numerous researchers, Adjara boasts the richest relict flora of Kolkheti in Georgia. Within this relatively small area, a wide range of ecosystems has evolved, from the wetland habitats of the Kolkheti plain to the distinctive ecosystems of the high mountains, where relict and endemic species still thrive. During the Ice Age, South Kolkheti, including Adjara, served as a refugium for ancient plant species (relicts).

The diversity and distinctiveness of Adjara's vegetation are evident in the Acharistskali River valley and its surrounding areas. The natural ecosystems here exhibit regular variation based on vertical zonation, slope exposure and steepness. Forest ecosystems are systematically distributed throughout the area, each occupying its unique eco-topological zone characterized by distinct ecological conditions.

Active human intervention in nature has triggered natural processes everywhere, and the mountain region of Adjara is no exception. Adjara is situated in a vulnerable zone and is considered one of the most challenging regions in the country in terms of natural processes. Unplanned and excessive consumption of local natural resources has led to landslides, destroying forests around villages, causing slope deformation, and resulting in the fragmentation, degradation, and destruction of vegetation. The natural renewal of ecosystems in these areas is a long and difficult process.

The most critical factor for slope stability and landslide development in mountainous Adjara is the saturation of slope rocks with excess atmospheric precipitation. This wetting disturbs the already weak static balance and triggers gravity processes [4]. There is limited information on the natural renewal of ecosystems in Adjara that have been damaged by these natural processes [5,6]. Therefore, studying the naturally regenerated forest phytocenoses on the slopes of mountainous Adjara, as well as the natural forests on adjacent slopes, is essential. This is especially relevant in the context of the derivation-type hydro power plant being constructed in the valley. Such studies are crucial for assessing the current ecological situation and for timely and competently determining preventive measures to address existing and anticipated ecological problems [12].

The purpose of the research was to examine the current ecological condition of natural and regenerated phytocenoses, determine the systematic structure of the flora, and conduct a geobotanical diagnosis of the phytocenoses. Additionally, the research aimed to evaluate soil fertility at the study locations and analyze it using multi-element analysis.

The study focused on the renewed forest ecosystems following the natural disaster in the Skhalta River valley (Khulo municipality), the natural forests on the surrounding slopes, and the soils developed under them. The Skhalta River, a left tributary of the Acharistskali, originates on the western slope of the Arsiani ridge at an altitude of 2220 meters above sea level. It has a length of 29 kilometers and a basin area of 223 m^2, and is fed by snow, rain, and underground water.

II. Methods

The main research method was traditional route expeditions. We conducted numerous floristic and geobotanical descriptions and performed a reconnaissance survey of the study area to understand the vegetation background. Using phytocenological diagnostics, we identified xenotypes through the Relevé method. Traditional method sofphytocenological research were employed for geobotanical descriptions [8, 10, 11].

We determined some agrochemical indicators of natural and regenerated forests oils that would allo wus to judge the level of soil fertility. Agrochemical analysis of soils were carried using classic, widely tested methods: Soil Ph was determined potentiometrically with a laboratory pH meter (Metter Toledo) in both aqueousand salt (KCl) extracts; Mobile P_2O_5 and K_2O were measured photometrically by Oniani's method in a single extract obtained by adding 0.1N H_2SO_4 to the soil; exchangeable CaO and MgO were analyzed titrimetrically using the trilonometric method; total Humus was determined by the Turin method, which involves oxidizing soil organic matter (containing carbon) with 0.4N $K_2Cr_2O_7$ in H_2SO_4, followed by titrationof the remaining bichromate with 0.1N Mori'ssalt $(NH_4)_2Fe(SO_4)\cdot 6H_2O$ using diphenylamine - $C_{12}H_{11}$ Nasan indicator; total Nitrogen was measured by the Kjeldahl method, which involves oxidizing humus carbon to carbon dioxide and converting amine (NH_2) nitrogen to anammoniacal form during soil digestionin concentrated H_2SO_4. To completely separate ammonia, the solution is made alkaline with 40% NaOH, causing the formed NH_3 to be transferred to 0.1N H_2SO_4 under boiling conditions. At this point, NH_3 combines with H_2SO_4 toform $(NH_4)_2SO_4$. The remaining free H_2SO_4 is then titrated with a 0.1N NaOH solution using Congo redasan indicator until a weak pink coloris achieved [1, 2].

Multi-element analysis of the soil was conducted using the modern method of instrumental research known as plasma atomic emission spectrometry (on instrument ICPE-9820). For this analysis, we prepared comparison (standard) solutions in advance, including on esolution that represented the internal standard, ytrium (Y):

I – ytrium standard solution - concentration 0,1ppm;

II standard solution - concentrations 5ppb and 25ppb;

III standard solution - concentrations - 2ppm ans 5 ppm.

The multi element standard solutions include: $Al, Sb, Ba, Pb, B, Ca, Cd, Cr, Co, Fe, K, Cu, Mg, Li, Mn, Mo, Na, Ni, P, Si, Ti, V, Zn, As, Be, Se, Tl$

Inductively coupled plasma spectrometryis a method of atomic emission spectrometry that uses inductively coupled argon plasmaas a source of atomic excitation. The method works by causing excitationan dionization, where each element emits a quantum of light at a specific wave length. Quantitative analysis involves measuring the amount of electromagnetic radiation, while qualitative analysis is based on the wavelength of the radiation. This method allows for simultaneous qualitative and quantitative analysis. Currently, it is the most widely used high-sensitivity method for element alanalysis of liquid and solid substances, with a correlation coefficient of at least 0.99 [9, 14].

III. Results

The wild flora of the regenerated forest comprises 105 species, grouped into 36 familie sand 88 genera [7]. In contrast, the wild flora of the boreal forests developed on the slopes suffered from landslide consists of 202 species, organized into 61 families and 152 genera.

The distribution of species into major taxonomic units is clearly illustrated in the diagrams.

The species diversity of the regenerated forest flora is significantly lower compared to the natural forests on the surrounding slopes (Table 1). In natural forests, the families distinguished by species richness are:*Asteraceae* - 32; *Lamiaceae*- 15; *Brassicaceae* - 9; *Rosaceae* - 9; *Dryopteridaceae* - 9;

Borraginaceae - 8; *Caryophyllaceae* - 8; *Scrophulariaceae* - 7; *Apiaceae*– 7. In regenerated forests, the families distinguished by species richness are: *Asteraceae*- 23; *Lamiaceae* - 8; Borraginaceae - 8; Brassicaceae - 7; Poaceae - 7; Scrophulariaceae - 4; Leguminosae - 4; Caryophyllaceae – 3. A significant portion of the wild flora consists of perennial herbaceous species, accounting for 69.5%, while annual herbaceous species make up 16%. Woody plants comprise 9.5% of the total.

The natural forests of the valley are polydominant and broad-leaved, with chestnut, oak, and beech as the dominant species. Typical phytocenoses include beech-larch-chestnut-leafy forests Fageto-Carpineto-Castanetumlaurocerasosum (Castanea sativa + Fagus orientalis + Carpinus caucasica – Laurocerasusofficinalis), hornbeam-chestnut-Cherry-laurel, Castaneto - Carpinetumlaurocerasosum (Castanea sativa + Carpinus caucasica - Laurocerasus officinalis), chestnut rhododendron, Castanetumrhododendronosum (Castanea sativa – Rhododendron ponticum), oak forest with rhododendron-Cherry-laurel, Quercetumrhododendronoso - laurocerasosum (Quercus hartwissiana + Rhododendron ponticum - Laurocerasus officinalis), beech forest with rhododendron, Fagetumrhododendrosum (Fagus orientalis – Rhododendron ponticum), chestnut-hornbeam-beech forest with blackberry, Castaneto-Carpineto-Fagetumrubosum (Fagus orientalis + Carpinus caucasica + Castanea sativa – Rubus caucasicus), Alder-grove with blackberry, Alnetumrubosum (Alnus barbata– Rubus caucasicus), Alder-grove braken blackberry, Alnetummatteuccioso-rubosum (Alnus barbata, Matteucciastruthiopteris, Rubus caucasicus). Natural regeneration of dominant species in forests is satisfactory in low-frequency groves (0,5-0,6), but weak in high-frequency groves (0,7-0,8).

Figure 1: *Natural vegetation of the valley*

Figure 2: *Naturally regenerated vegetation of the valley*

Naturally regenerated forests are pine forests (Pineta; Pinus sosnovskyi). Coenoses featuring alder grove on well-moistened soils in *the relatively leveled areas of the slope.* In pine groves, individual occurrences of Spruce, Silver-fir, hornbeam and Yew-tree can be found. We have described typical phytocenoses: *the pine grove with buckthorn sub forest Pinetum Ramnosum (Pinus Sosnovski-Ramnusimeretina); Alder-grove-pine forest, Alnetum Pinetozum (Pinus Sosnovski+Alnusbarbata); Alder-grove with buckthorn sub forest Alnetumramnosum (Alnus barbata+Ramnusimeretika); Alder-willow grove Alnetumsalixsosum* (Alnus barbata+Salix alba); In pine forests with low regeneration frequency, the natural regeneration of pine is satisfactory. However, the following species exhibit weak natural regeneration: *Piceaorientalis, Abies mordmaniana, Taxus bacatta, Alnus barbata, Ramnusimeretina.*

The soils of broad-leaved forests, including chestnut, oak, mixed (polydominant), and beech forests, represented by typical fulvous forests oils. In contrast, regenerated forest soils are characterized by being loamy, stony, and low inhumus.

Soil samples were collected from the surface at a depth of 0-20 cm for agrochemical analysis and to assess fertility levels. Upon arrival at the laboratory, the samples were spread on dense paper and allowed to air dry for 3-5 days. The soil was then cleaned of impurities, ground, sieved through a 1 mm diameter sieve, and stored in a hermetically sealed labeled container for analysis. The agrochemical indicators of the soils are detailed in Table 2. It is evident from these indicators that the main quality parameters of the regenerated forest soil (sample No. 1) are inferior to those of the natural forest soil. This includes its active reaction and the quality of basic nutrients, humus and nitrogen. The regenerated forest soil has average or below-average concentrations of essential plant nutrients, including phosphorus, potassium, calcium, and magnesium.

Table 2: *Some agrochemical indicators of natural and regenerated forest soils*

№	Samplinglocation	sampling depth, cm	pH		mobileformsofnutrients, mg/100 ginthesoil				Total, %	
			H_2O	KCl	P_2O_5	K_2O	CaO	MgO	humus	nitrogen
1	soilfromtheregeneratedforest	0–20	4.85	3.47	59.10	29.4	21.56	11.90	3.68	0.13
2	naturalforestsoil	0–20	6.58	5.69	72,30	44.6	78.47	46.21	5.62	1.90

To perform the multi-element alanalysis, an aqueous extract of the soils was prepared with a soil-to-water ratio of 1:25. The analysis results were compared with the maximum allow able concentrations of heavy metals established by the environmental quality standards approved by the Republic of Georgia. This comparison was made to prevent adverse effects on the environment and human health due to environmental and anthropogenic factors [3].

The conducted studies allowed us to judge the content of microelements and some heavymetals in the research soils in relationt to their maximum permissible concentrations (MPC)

(Table 3). The content of copper and lead in the natural forest soil exceeded the permissible concentration. As for the soil of the regenerated forest, there was an excess of concentration of several elements in relation to MPC. The seelements are: copper; manganese; zinc; plumbum.

Table 3: *Multi-element analysis of aqueous extracts from soil Concentration of microelements, mg/kg*

IV. Discussion

I. Floristic and Coenological Analysis of Natural and Regenerated Forest Ecosystems

Forest phytocenoses on the slopes affected by landslides develop primarily in zones at an altitude of 750–1000 meters, mostly on slopes with an eastern exposure, where they in habit slightly moistened areas. The natural form at ion of secondary phytocenosesis quite dynamic, influenced by local climatic and soil conditions. Over the years, as woody plants grow on the baresubstrate, a tiered structure of phytocenosis gradually forms (see Fig. 3 and Fig. 4). The primary layer of secondary natural forest phytocenoses is predominantly composed of pine (Pinus Sosnovski), within dividual representations in some places of alder (Alnusbarbata), spruce (Piceaorientalis), sochi (Abiesnordmaniana), willow (Salixalba), and horn beam (Carpinus caucasica). Depending on the intensity of plant growth influenced by local climatic and soil conditions, the sub-tiersoft hemainlayer have naturally formed. The over all density of the groves in most phytocenoses ranges from 0,5 to 0,6. Typically, the main forest exhibits unevendensity, which significantly impacts the floristic composition and structure of the understory and herbaceous cover in the lower levels. The understory is unevenly developed, featuring species such as Ramnusimeretina, Ilexcolchica, Rhuscoriaria, and Swidaaustralis. The herbaceous cover is primarily composed of perennial species, with relatively high projected coverage in open areas and gaps: Athyriumfilix-femina, Crepisfaetida, C. foetida, Hieraciumpilosella, Echiumvulgare, Fragariavesca, Brachypodiumsilvatica, Trifoliumcampestra,T. pratese, T. arvense, Poaannua, Mycelismuralis, Sambucusebulus, Plantagolanceolata, Tunicasaxifraga,Circiumimeretina, Teucriumnuchense, Clematisvitalba, Hipericumperforiatum, Eupatoriumcannabinum and other.

The natural regeneration of pine on the slopes of the renewed forest is progressing satisfactorily. However, species such as Piceaorientalis, Abiesnordmaniana, Taxusbaccata, Alnusbarbata, and Ramnusimeret in a exhibit weak natural regeneration. This indicates that while a system of natural renewal existsin secondary natural phytocenoses, the development of monoclimax ecosystems in the near future seems unlikely.

Figure 3: *Slopes affected by landslides 1989 affectedbylandslides*

Figure 4: *Secondary natural forests on the places*

II. Agrochemical Indicators of Soil.

The experimental study of the soils revealed that the natural forest soil has significantly higher fertility compared to there generated forest soil. Specifically, the pH in KCl suspensionis 3.47, indicating a moderately acidic reaction. The levels of mobile phosphorus and potassium are average (59.10 and 29.4 mg/100g of soil respectively). However, the concentrations of mobile Caand Mg which are important for the soil's buffering capacity, are below average (21.56 and 11.90 mg/100g). Additionally, the soils are deficient in total humus (3.68%) and total nitrogen (0.13%), which are crucial indicators of soil quality and fertility (Table 2).

In the natural forest sample (sample №2), the pH in KCl suspension is 5.69, placing it in the weakly acidic range. The soil is well-supplied with essential nutrients, including calcium (78.47 mg/100g) and magnesium (46.21 mg/100g). The content of mobile phosphorus in the natural forest soil is higher by 13.2 mg, and the mobile potassium content is higher by 15.2 mg compared to the regenerated forest soil. Consequently, the natural forest soil is adequately provided with these nutrients. A similar pattern is observed for total humus and nitrogen content, with these indicators being 1.94% and 1.77% higher, respectively, in the 1st sample compared to the 2nd sample.

III. Multi-element Analysis of Soil.

The content of mercury, lithium, antimony, selenium, titanium, thallium, and vanadium is below the detection limitin both regenerated and natural forest soil samples. Additionally, the levels of arsenic, boron, barium, cobalt, molybdenum, chromium, and cadmium do not exceed the permissible concentration in any of the samples.

The content of Cu (3.850 mg/kg) and Pb (2.537 mg/kg) in natural forest soil was higher than maximal permissible concentration (MPC). As for the soil of the regenerated forest, there was an excess of concentration of several elements at the same time, in relation to MPC. These elements are: Cu-4.465mg/kg; Mn-1.348mg/kg; Zn-5.983mg/kg; Pb-2.866 mg/kg.

The elevated concentrations of the mentioned metals are likely attributed to the proximity of the Skhalta HPP to the slopes. The water reservoir of the HPP is fedby the Chirukhi River, whichdischargeswaterfromthederivationtunnel. During the tunnel's construction, crushed rocks were placed and spread over the surrounding slopes, potentially leading to increased levels of these heavy metals in the soil.

The current situation under scores the need for systematic research and monitoring of soil chemical composition. This will help assess the current state of the soil and enable timely preventive measures to improve soil quality.

PROBLEMS IN ASSESSING THE VULNERABILITY OF BUILDINGS AND STRUCTURES IN THE CONTEXT OF CLIMATE CHANGE

Gennady Nigmetov

•

All-Russian Research Institute for Civil Defense and Emergency Situations, RUSSIA
tagirmaks@mail.ru

Abstract

Already, we are increasingly encountering the consequences of dangerous climate impacts on buildings and structures. These effects are particularly evident in the thawing of permafrost, geological hazards, floods, mudflows, as well as forest and landscape fires. Of course, climate change also influences seismic and tsunami risks.
To plan protective measures for populations in hazardous zones in a timely manner, it is necessary to be able to predict the parameters of these dangers, assess the vulnerability of buildings and structures, and evaluate the risks to the population. By understanding the hazards, vulnerabilities, and risks, appropriate measures to reduce risks can be developed.

Keywords: technical condition of buildings, vulnerability of buildings, vulnerability of soils beneath buildings, individual risk for the population, risk reduction

I. Introduction

The most effective way to protect buildings from hazards associated with climate change and the reduced bearing capacity of soils is a reliable structural design of buildings and structures that provides protection against dangerous changes. However, it is not always possible to design and build buildings that are immune to vulnerabilities. Therefore, in order to prevent possible accidents, it is important to be able to quickly and reliably assess the technical condition and vulnerability of the "soil-building" system.

If we analyze what is more dangerous for the "soil-building" system, it is obvious that the most hazardous aspect is the emergency technical condition of both the building and the soil mass, as elements of an interconnected system [2].

Unfortunately, traditional methods of design, construction, and operation do not account for the possibility of errors at these critical stages. At the investigation stage, errors arise due to the limited capabilities of point-based drilling, as soil properties between boreholes are interpolated. Soil samples sent to laboratories for testing often lose their natural physical and mechanical properties during transport. During the design stage, errors are amplified due to inaccuracies related to soil conditions, which can be further exacerbated by the lack of consideration for climate change. Fast-paced competitive construction leads to underestimation of the importance of adhering to all design conditions, such as incomplete driving of foundation piles, poor quality of expansion joints, and inadequate implementation of soil paving and drainage around the building [3].

Figure 1: *A new framed residential building that has undergone significant deformation due to the thawing of soils in permafrost conditions*

II. Methods

For timely diagnostics of the technical condition of the soil mass and its suitability for construction, effective and accurate methods are needed that provide three-dimensional data about the structure of the soil mass and potential hazard zones within it. Such three-dimensional data on the stiffness of the soil mass can be obtained through its natural vibration frequencies. Heterogeneous hazard zones within the soil mass emit high-frequency acoustic noise. When building vulnerability decreases, the frequency of its natural vibrations also decreases.

A technology is required that can capture the frequency characteristics of the "soil-building" system and determine its stiffness, potential hazards, technical condition, and vulnerability based on frequency data. By identifying hazards and vulnerabilities, it is possible to determine potential consequences and the individual risk to the population using the geographic information system (GIS) "Extremum" [3, 4].

III. Results

The calculation of potential consequences from repeated strong impacts must take into account the possible decline in the technical condition and vulnerability of buildings. Currently, such a procedure is not provided in the GIS "Extremum." For the prompt assessment of the technical condition and seismic resistance of buildings, it is proposed to use the method of dynamic testing [11,13]. Based on the results of dynamic tests, the building database in the GIS "Extremum" can be updated.

In the GIS "Extremum," the current classification system for building databases is based on the MSK-64 seismic scale, and buildings are categorized into type A (constructed from local materials), type B (stone and block structures), and type C (seismically resistant, categories C7, C8, and C9). The proportion of building types in the database used for assessing the consequences of major earthquakes in certain areas is represented as percentages (see Table 3.2). [5]

Figure 2: *An example of mixed, dense development in the city of Istanbul on hilly terrain*

Table 1: *Example of database entry for buildings classified by type (based on data from 1999-2000, from the GIS "Extremum" database).*

City name	A/ Height, m	B/ Height, m	C6/ Height, m	C7/ Height, m	C8/ Height, m	C9/ Height, m
Nalchik	0,2/3	0,21/6	0,2/15	0,39/3	0	0

As seen from the example (see Table 1), in the examined city, according to data from 1999-2000, there are no buildings with seismic resistance of categories C8 and C9. This example makes it clear that the seismic resistance database requires constant updating. The seismic resistance data are tied to the seismic scale and provide only discrete values of seismic resistance without considering operational wear, meaning they do not reflect the actual seismic performance of buildings. The GIS "Extremum" database needs adjustments, and it can be used for preliminary analysis. The database can be updated either by decreasing or increasing the share of buildings in categories A, B, C6, C7, C8, C9, or by dividing the city's territory into separate areas with predominant seismic resistance values.

To assess the technical condition, stiffness, and seismic resistance of buildings and structures, it is proposed to use the "Struna" technology [11]. The essence of the method is based on the fact that through oscillations, the stiffness of the structure can be evaluated, and through stiffness, the technical condition and seismic resistance of the buildings can be assessed.

For evaluating possible resonance between the ground and the building, sensors are installed on both the ground and the building.

Stiffness deficiency is assessed using the following dependencies [4–8]:

$$\Delta fx = ([fx]2-fx2)\times 100/ [fx]2, (1)$$

$$\Delta fy = ([fy]2-fy2)\times 100/ [fy]2 , (2)$$

$$\Delta fz = ([fz]2-fz2)\times 100/ [fz]2, (3)$$

where fx, fy, fz are the values of the building's natural vibration frequencies obtained from dynamic tests.

[fx], [fy], [fz] are the standard natural vibration frequencies obtained from the design or calculated values.

Δfx, Δfy, Δfz are the stiffness deficiencies in percentages along the X, Y, Z axes (see Table 2).

Based on the obtained data on stiffness deficiency, the technical condition and seismic resistance of the buildings are determined [6].

Table 2: *Percentage of stiffness reduction (square of the building's natural vibration frequency), depending on the category of technical condition*

Type of Structure	Percentage of Relative Stiffness Reduction of a Structure in Various Conditions				
	Very good	good	fair	poor	very poor
Reinforced Concrete Frame	0–25	25–43	43–57	57–71,4	71,4–100
Steel Frame	0–16,7	16,7–33	33–50	50–67	67–100
Brick	0–16,7	16,7–33	33–50	50–75	75–100
Wooden	0–20	20–27	27–40	40–67	67–100
For Other Types of Buildings and Structures, Soil Masses Beneath Buildings	0-10	11-30	31-60	61-90	

Dynamic testing is proposed to be conducted on characteristic typical elements of settlements with uniform building types. Data on seismic resistance (see Table 3) for each building element should be entered into the GIS database. The seismic resistance of buildings is proposed to be determined by the following formula:

$$A = \frac{4*\pi^2*\Delta d}{k_0*k_1*k_\varphi*\beta(T)*T^2} \quad (4)$$

where

Δd – the maximum allowable displacement of the building;

k_0 – coefficient accounting for the structural design features and its importance, K_0 [4];

k_1 – coefficient accounting for allowable damage, k_1;

$k\varphi$ – coefficient accounting for the dissipative properties of the structure, $k\varphi$;

$\beta(T)$ – coefficient of the building's dynamic response;

T – period of the building's natural vibrations.

Based on the results of dynamic testing, knowing the category of technical condition, the probability of human injury can be determined

The individual risk of people being in damaged buildings in the considered hazardous area over the projected time interval, taking into account possible repeated impacts, is proposed to be calculated using the following formula:

$$Re_i(t)=P_z\times\sum_i^n m_i/(N_i\times T) \leq [Re_i] \quad (5)$$

where

P_z - probability of the primary (or repeated) strong impact on the building;

m_i – estimated human losses in the event of failure of the "soil-building" system's bearing capacity in the considered i-th element of the area (building) after the impact [4, 10, 11];

N_i – number of people in the i-th element who fall into the danger zone leading to building damage;

T – the period during which the primary (or repeated) impact leading to building damage will occur;

$[Re_i]$ - risk norm of 10^{-5} .

The mathematical expectation of population losses is calculated using the "Extremum" geographic information system (GIS) [7].

Let us consider an example of assessing karst hazard for the soil mass in the area of a two-story building made of silicate brick. The building is two stories high.

Based on the results of dynamic-geophysical tests, the natural vibration frequencies of the soil and the building, as well as accelerations and damping decrements in the spatial coordinate system X, Y, Z, were obtained. Examples of measurements taken at the site in 2022-2023 are shown in Figures 3-4.

To assess the karst hazard of the construction site, the data on soil mass vibration frequencies in the low-frequency range (up to 20 Hz) and high-frequency range (from 0.1 to 400 Hz) were converted into a hazard parameter ranging from 0 to 10 points. The technical condition of the building blocks was evaluated by comparing the normative values and the squares of the natural vibration frequencies of the blocks obtained from the tests.

In Figures 3-4, the formation of karst hazards is visible in the form of high-frequency noises at frequencies of 60-120 Hz and periodic pulses, repeating every 0.5-1 second, with amplitudes exceeding the background microseismic vibrations by more than 10 times. To create maps of karst hazard for the site, dynamic-geophysical measurement data, depending on the values of the parameters and their level of "noise," were rated (Fig. 5).

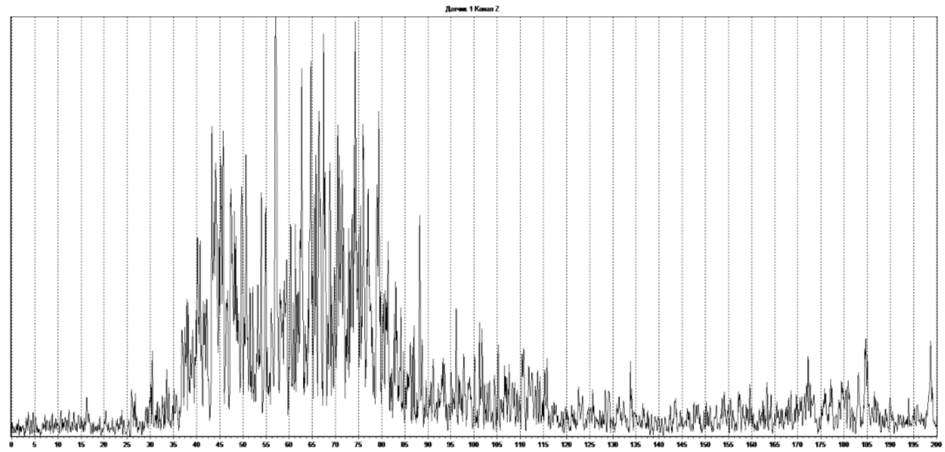

Figure 3: *Vibration spectrum of the "soil-building" system along the Z-axis, data from 2022*.

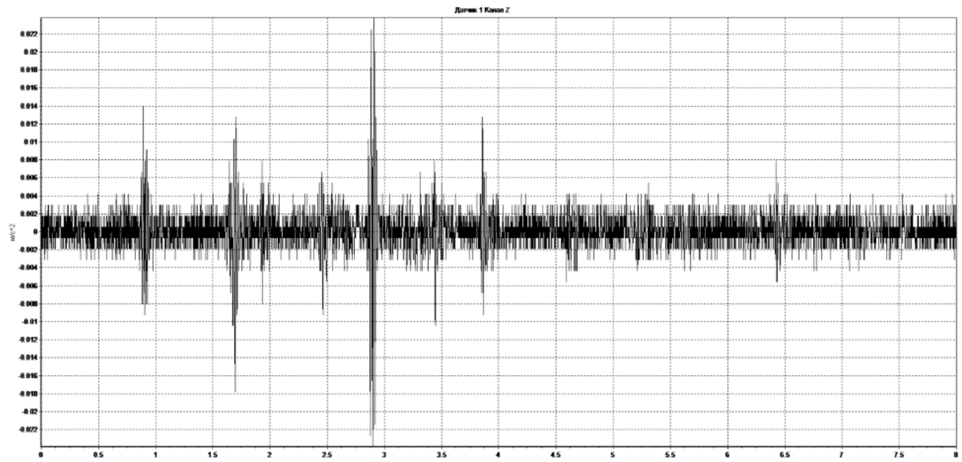

Figure 4: *Vibrations of the "soil-building" system along the Z-axis, data from 2022.*

Figure 5: *Zones of increased karst hazard (marked in red).*

IV. Discussion

The use of the dynamic-geophysical testing method allows for the rapid identification of stiffness deficiencies in the "soil-building" system and the assessment of building vulnerability. By knowing the vulnerability or technical condition of buildings, it is possible to determine the probability and expected losses, as well as calculate individual risk.

With the value of individual risk for the forecasted area, it becomes possible to plan risk reduction measures in a timely manner.

Abstract

The article proposes a method for calculating the solar energy potential for the Republic of Azerbaijan and presents the obtained results. The annual amount of sunlight falling on the territory of the Republic of Azerbaijan has been scientifically analyzed. The results obtained on a sample solar collector on the use of solar thermal energy are presented. The experiments were carried out in the summer months and the results show that the highest temperature in the solar collector during the day is obtained in the second half of the day. Here, as a result of the experiments, the dependence of the temperature on the hours of the day is graphed.

Keywords: Solar energy, solar collector, solar energy potential, thermal energy, technical potential

I. Introduction

The development of green energy and the access of green energy to world markets are currently the priority of Azerbaijan's energy policy. Expanding the use of renewable energy sources in the field of energy in our country has been put forward as a priority task by our state, and the goal of increasing the share of renewable energy in the installed capacity of electricity to 30 percent by 2030 has been determined. Also, the 29th session of the Conference of the Parties to the UN Framework Convention on Climate Change (COP29), which will be held in our country, will create new approaches to climate change and promote cooperation between various stakeholders. Everyone in the world will once again see that our agenda is about green energy. To combat climate change, significantly reduce greenhouse gas emissions to reduce risks in this area, achieve technology transfer to achieve low-carbon development worldwide, finance renewable energy, as well as find other innovative solutions to reduce emissions and adapt to climate impacts, it is important to expand policies promoting the use of renewable energy, grid integration and energy efficiency measures. Expanding the use of solar energy is one of the important tasks in the direction of reducing greenhouse gases in our country. Huge projects are being implemented in our country in the direction of purchasing electricity from solar energy, but the production of thermal energy is just as important.

The Republic of Azerbaijan is rich in solar, wind and other renewable energy sources and has highly qualified specialists for their use. The use of ecologically and economically favorable solar energy is of great importance in our country. The values of insolation in cloudless air are 800÷1000 kW·h/m² during the year for the Absheron peninsula and the Caspian coastal strip. The number of sunny hours here is 2500 hours per year. For the Autonomous Republic of Nakhchivan, these figures are more appropriate, 1100÷1200 kWh/m² and 2900 hours, respectively.

Modern photovoltaic modules are solar installations available to provide industrial facilities, residential areas and commercial facilities with high technical characteristics. At the same time, these devices convert direct current energy into alternating current energy by means of an inverter and are used to create a reliable energy source.

Among the methods of using solar energy, two options of photothermal conversion are used more: heat supply of residential, communal and agricultural enterprises; obtaining electricity by means of steam and gas turbines.

The first option is used more often, there is little transition to the use of the second option.

The potential amount of solar energy of the region means the total amount of solar radiation falling on the territory of the region during one year and depends on the climatic conditions of this region (Eum, kWh/(m²·year)). The linear size of potentially measured zones is taken up to 200 km.

II. Methods

Cadastral data is used to determine solar energy potential. The displayed data should reflect the spatio-temporal dynamics of solar radiation fall and the characteristics of meteorological factors affecting it. The following information is usually included in the solar cadastre: average monthly and average annual total cloudiness; probability of clear and cloudy skies; clear air attendance coefficient; average monthly and average annual duration of solar radiation; average hourly values of the main elements of solar radiation incident on a horizontal surface under conditions of medium cloudiness. Usually 0.1% of the incident solar radiation is attributed to the technical potential. The annual duration (in hours) of the length of the day at the 38-42nd parallels of heliograph observations at the meteorological stations in the territory of the Republic of Azerbaijan was determined.

At the limit of the atmosphere, the solar radiation falling on the horizontal plane can be calculated analytically. Actinometric observations cannot be made at all locations, but analytically, it is possible to calculate the horizontal solar radiation falling on the surface at the upper boundary of the atmosphere at any latitude with great accuracy. The values of solar radiation were calculated in 1 degree increments for latitude circles covering the entire territory of the Republic of Azerbaijan, i.e. from the 38th latitude to the 42nd latitude, and are shown graphically in Figure 1. As can be seen from the graph, due to the small size of the area, solar radiation values are almost unchanged in the hot season, while in the cold season, small differences in latitude are observed.

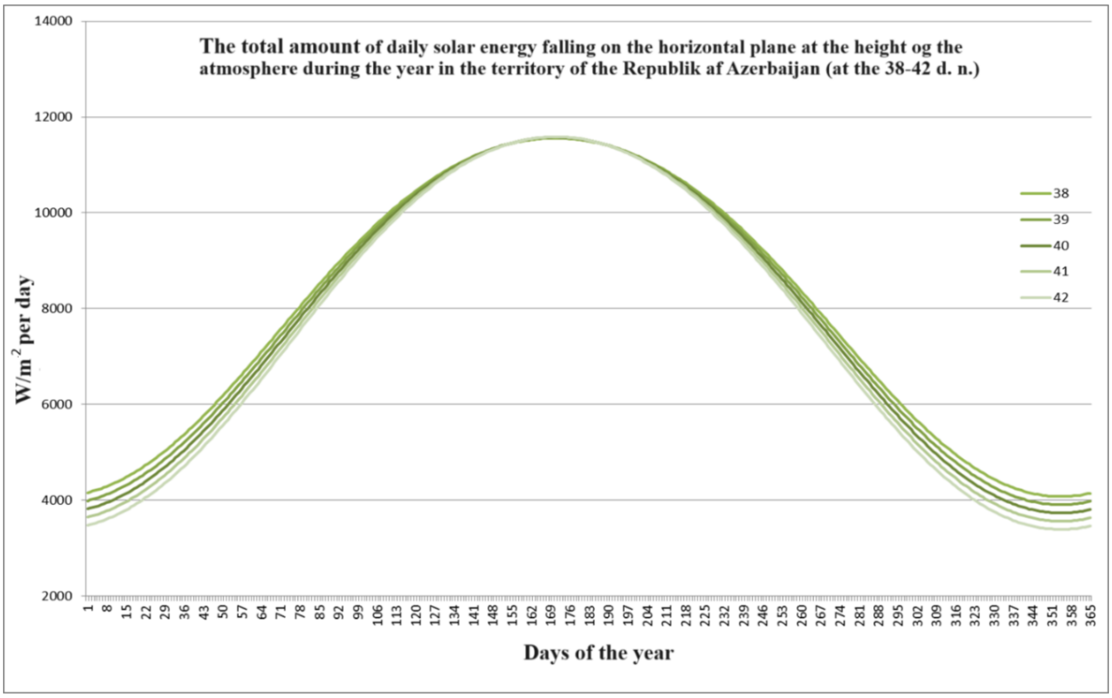

Figure 1: *The graph of changes in solar radiation values depending on the season*

The technical potential of heat and electric energy of the area is taken as the sum of heat and electric energy produced by the taken technical means. During the determination of thermal energy, the technical characteristics of the technical device, i.e. the solar collector, are taken. In the determination of electric power, the energy characteristics of photoelectric devices are considered as the basis.

III. Results

The technical potential of Solar Energy is calculated as follows:

$$E_{tex} = E_{tot} * S * \tau * \eta_{sp} * \eta_0 \quad (1)$$

$\boldsymbol{E_{tex}}$- technical potential of solar energy
$\boldsymbol{E_{tot}}$- solar energy total potential
$\boldsymbol{S}$ - solar panel area (m^2)
$\boldsymbol{\tau}$ – light emission capacity of the solar panel (0.85)
$\boldsymbol{\eta_{sp}}$- useful work coefficient of the solar panel (0.15)
$\boldsymbol{\eta_0}$- useful work coefficient of energy conversion and transmission to the consumer (0.83)
$\boldsymbol{\eta_0}$ - is calculated in the following manner

$$\eta_0 = K * \eta_{conv} * \eta_{tran} \quad (2)$$

here
η_{conv} – conversion – useful efficiency of conversion (0.9)
η_{tran} – transmission-is the useful efficiency of the transmission (0.95)
K – is the coefficient according to the angle of inclination of the panel.

When the inclination angle is equal to the width of the point, K=1.3, that is, the radiation increases by 30%.

Accepting the above coefficients, we can calculate the technical potential of solar energy in the following manner:

$$E_{tex} = E_{tot} * 1 * 0.85 * 0.12 * 0.83 = 0.085 * K * E_{tot} \quad (3)$$

Table 1 shows the potential of solar energy calculated in the above manner. For a given solar installation, the average annual technical potential of the area with horizontal panels is 121.23 kWh per square meter. At this time, the average technical potential of the area fluctuates between 100-160 kWh.

We find the average technical power of solar installations as follows:

$$\bar{P} = \frac{E_{tex}}{8760} \quad (4)$$

The power of technical potential is 8-15 W/m^2 in January, and 22-36 W/m^2 in July. Average annual prices are 15-23 W/m^2.

The solar energy potential of the Republic of Azerbaijan and its administrative regions was calculated separately using the above formulas, data from hydrometeorological stations and research results of ANAS institutes. Areas suitable for agriculture, areas of forest funds were not taken into account in the calculations (parameters for several cities and regions are presented in Table 1).

Table 1: *Solar energy potential of the administrative regions of the Republic of Azerbaijan*

№	The name of the areas	Common area, huh	K/t usable area, huh	K/t usable area, huh	Areas suitable for the use of solar energy, yes

9	total for Azerbaijan;	8641506	4514473	1063480	3063553

Using solar radiation parameters, the technical potential of administrative regions, large cities and the country as a whole was determined (Table 2).

As can be seen from the tables, the solar energy potential of the Republic of Azerbaijan is 47.5 billion kWh and the technical potential to be achieved with the solar panels to be installed is 43.2 thousand MW. Using this potential, it is possible to obtain a large amount of funds from the export of oil and gas resources of our country.

It is more efficient to use solar collectors in relatively warm areas of the country. Our newly designed solar collector is similar to the solar collector used for air heating with a number of changes.

Stainless steel plates with a thickness of 0.5 - 2 mm are used in the preparation of the solar collector to increase the service life and reduce the cost (Fig. 2). As you can see, the lower part of the solar collector is made of a rectangular prism, and the upper part is made of a trapezoidal prism. In the lower part, the water is heated by the sun's rays, moves up and is put to use. In order to reduce heat losses, the lower part of the solar collector is covered with heat insulating material.

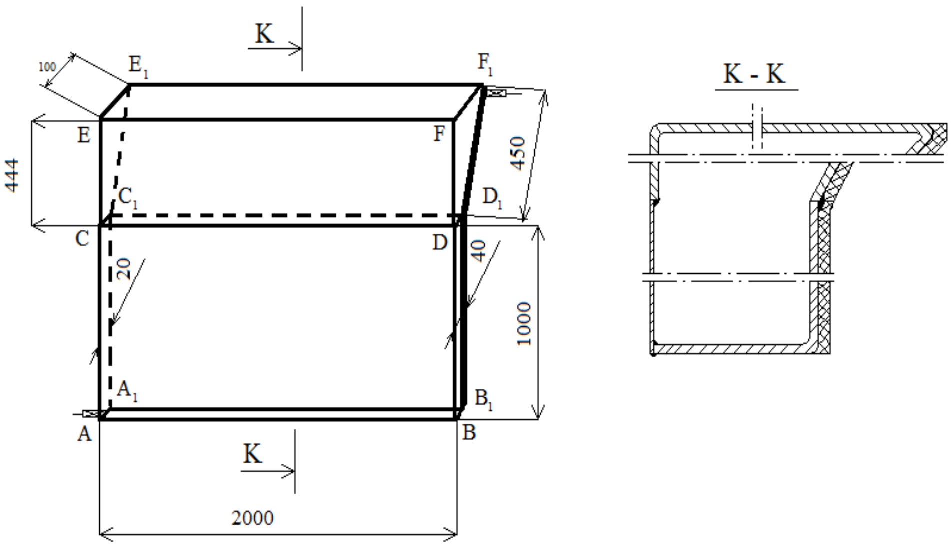

Figure 2: *Stainless steel plates*

Experiments were carried out in the middle of July on the Absheron Peninsula using the provided solar collector, and it was determined that the highest water temperature was obtained through the solar collector around 16:00.

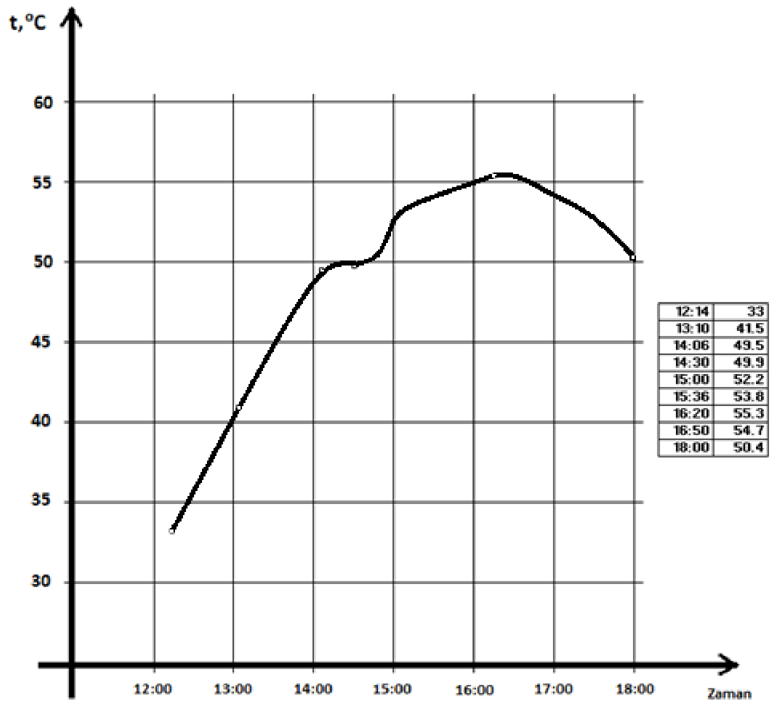

Figure 3: *Water temperature*

Our country has great resources for the production of both electricity and heat energy from solar energy. Investments by the public and private sector are essential for the utilization of these resources. With this, new jobs will be opened, energy security, environmental cleanliness and export potential of traditional energy resources will be achieved.

IV. Conclusion

Expanding the use of solar energy is one of the important tasks in the direction of reducing greenhouse gases in our country. Huge projects are being implemented in our country in the direction of purchasing electricity from solar energy, but the production of thermal energy is just as important.

The Republic of Azerbaijan is rich in solar, wind and other renewable energy sources and has highly qualified specialists for their use. The use of ecologically and economically favorable solar energy is of great importance in our country.

Abstract

In September 2023, an unmanned aerial vehicle was used to conduct airborne laser scanning and aerial photography in the Makazhoy Basin, where the carbon testing ground of the A.A. Kadyrov Chechen State University is located. As a result, a highly accurate digital elevation model (DEM) was compiled for areas of about 170 hectares located on opposite macroslopes of the basin at comparable hypsometric levels (1700-2200 m). Subsequent processing of the DEM using ArcGis software allowed us to quantitatively characterize the microrelief of the test sites and identify, based on morphometric analysis and semi-automated interpretation, the terraces on the mountain slopes that were previously used for agriculture. It was found that the previously existing settlement and farming system in this area took into account the natural resource potential of the mountain slopes. In this regard, the northern macroslopes of the Makazhoy Basin are characterized by greater productivity of natural ecosystems compared to the southern ones. The consequence of these natural causes is that the terraces on the northern macroslope occupy 46% of the test site area, while on the southern one - 26%.

Keywords: Makazhos basin, carbon landfill, aerial laser scanning, unmanned aerial vehicles, digital terrain model, terraces

I. Introduction

Currently, the process of involving mountain territories in economic turnover is accelerating. If in the second half of the 20th century, depopulation of the mountains and a decrease in economic activity were noted here, now they are again attracting attention from the point of view of economic development. This is, not least, due to the fact that the quality of agricultural products produced in the mountains is often higher due to the lower level of pollution of these territories. However, the process of re-involving mountain territories in agricultural turnover should be based on the principles of sustainable development, implying the preservation of the habitat and the minimization of the negative impact on the environment. This is possible on the basis of comprehensive information about the area of economic development.

In the North Caucasus, including the territory of the Chechen Republic, mountainous territories were used for distant-pasture livestock farming. In the warm season, mainly small cattle were driven to high-mountain pastures, where they stayed for almost the entire warm period. In the cold period, they were driven to the flat part, where they wintered. However, within the mountain basins, it was possible to keep farm animals all year round, which was facilitated by natural conditions. Basins are closed territories to varying degrees, formed either by the main ridges or confined to the valleys of the largest rivers. This kind of isolation leads to the formation of a warmer and drier climate and a wider range of soil and plant groups, the spatial distribution of which is determined by local relief features. In this regard, mountain basins were populated and developed quite a long time ago throughout the entire territory of the North Caucasus. This is especially expressed in the largest and most clearly expressed tectonic depression, located to the south of the Rocky Ridge – the North-Jurassic. The basins in the Inner-Mountain Dagestan are also widely expressed.

In this regard, our research covered the Makazhoyskaya depression, located in the southeastern part of the Chechen Republic, on the border with Dagestan. The orographic boundaries of the depression are expressed differently and are represented by a number of ridges.

In the north, the border runs along the Kashekrlam ridge, which further northeast approaches Lake Kezenoy-Am. The eastern border is confined to the spurs of the Gagotytlyur ridge. The southeastern border extends along the local watershed with heights of up to 2500-2600 m. From it, in the Ansalty canyon, the orographic line extends to the south and is expressed by the Khindoy-lam ridge, extending strictly to the west, where at the extreme western point the orographic line extends strictly to the north, after which it turns east-southeast to the watershed between the Akhkete River basin (a tributary of the Ansalty) and the Keloy-akhk, which flows into the Sharo-Argun. The area of the basin within the specified boundaries is 144 km^2 (Fig. 1, 2).

Figure 1: *Chechen Republic. Physical map*

Interest in the Makazhoy depression is also associated with the fact that the carbon testing ground of the Chechen State University named after A.A. Kadyrov is located here, one of the tasks of which is to develop a methodology for regenerative livestock farming in mountainous conditions.

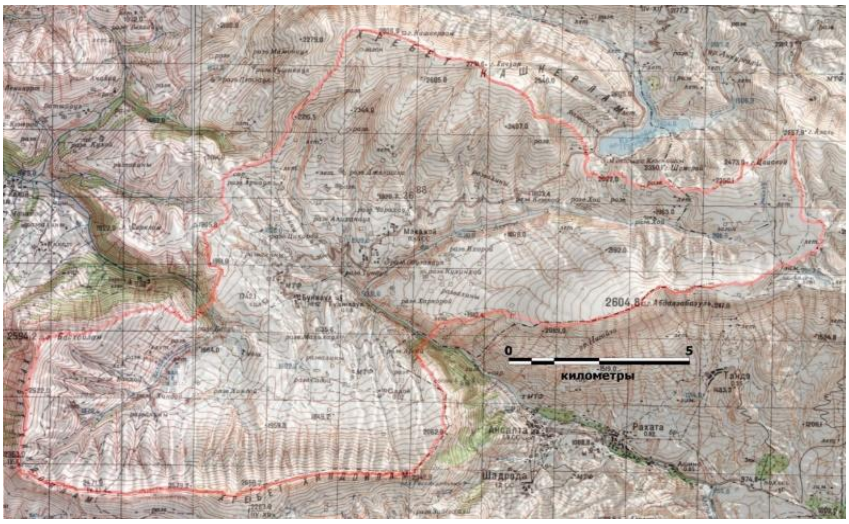

Figure 2: *Position and orographic features of the Makazhoy basin*

Previously, an analysis of the relief of the depression was carried out based on the digital elevation model of the average spatial resolution of the European Space Agency FABDEM V1-0 with a resolution in this part of about 27 m [3] using standard methods [4-6]. It was found that the depression is dominated by heights of 1600-2000 m, which account for 43.0% of the territory, the most common slopes are 10-15 ° (23.8%), 20-30 ° (23.5%) and 5-10 ° (19.7%). As for the exposure, the southern (16.6%) and northwestern (16.2%) slopes are most widely represented. These macro-exposure differences determined not only the distribution of the soil and vegetation cover across the basin, but also its economic development, which manifested itself in the terracing of the slopes. They are reflected in the modern microrelief, are clearly visible during a visual inspection of the territory and are its peculiarity. However, they are not revealed by the global digital elevation model due to its low spatial resolution. In this regard, detailed high-precision studies based on other methods are necessary.

Currently, unmanned aerial vehicles (UAVs) are actively used to obtain detailed information about the microrelief of a territory, which allows for prompt receipt of information at a local level [1, 2]. Aerial photography (AP) and airborne laser scanning (ALS) are used for these purposes. These high-tech methods of collecting geospatial data allow for obtaining detailed digital models of relief and terrain, as well as orthophoto plans, which are then used for geospatial analysis of mapped territories.

II. Methods

In the autumn of 2023, field studies and airborne geodetic works were carried out in the Makazhoy Basin, which included geodetic works, aerial photography and airborne laser scanning [7]. The survey sites were located in the eastern part of the basin in the altitude intervals of 1700-2200 m and covered 2 sites. Highly detailed AFS was carried out on 2 sites. The first of them is the territory of the carbon test site of the A.A. Kadyrov ChSU, where the regenerative livestock farming technology is being developed, located on the northern macroslope of the Makazhoy Basin. The area of this site is 168.0 hectares. The second site is located on the opposite, southern macroslope of the basin, and occupies an area of 169.4 hectares (Fig. 3).

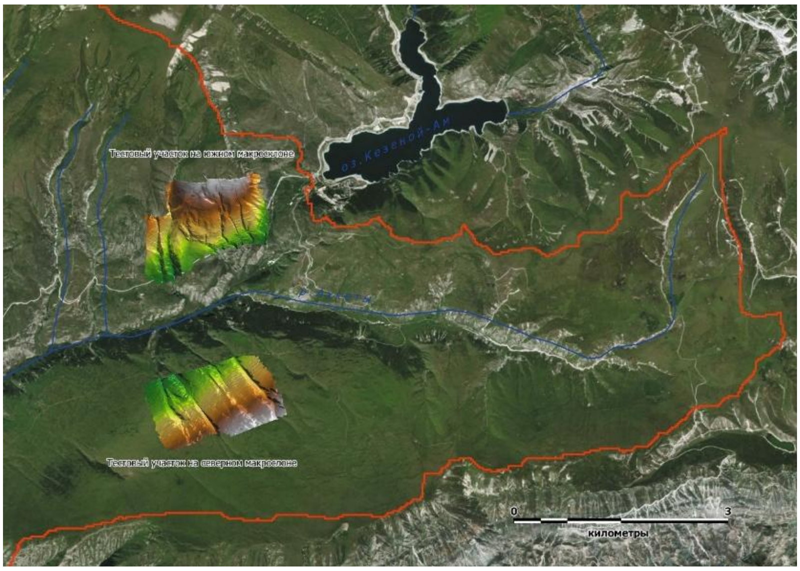

Figure 3: *Location of test sites within the Makazhoy basin*

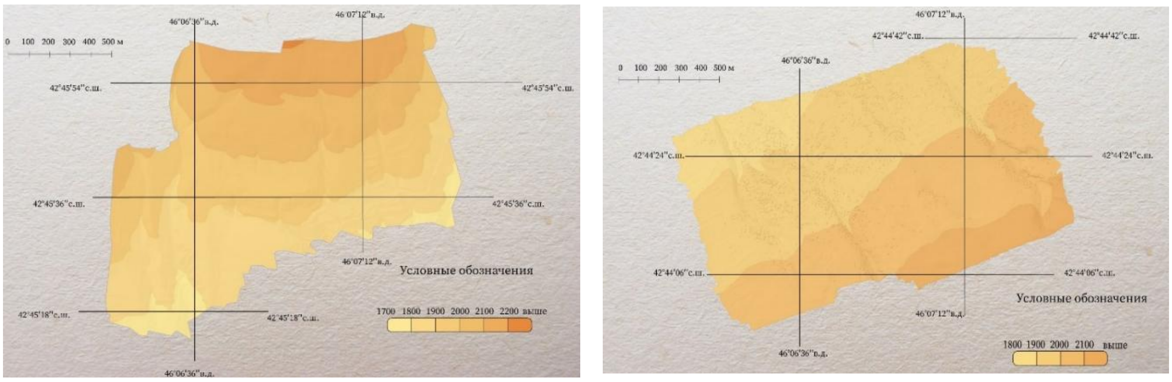
Aerial photography and airborne laser scanning were carried out using the GEOSCAN 401 Lidar UAV by staff and students of the Moscow State University of Geodesy and Cartography and the A.A. Kadyrov Chechen State University. Photogrammetric processing of the aerial photography results was performed using Agisoft Metashape software. Point clouds obtained using the UAV were processed in Terrascan and Credo 3D SCAN software. As a result, it became possible to separate points into the "land" and "vegetation" classes, and highly accurate digital elevation models with a resolution of 0.1 m were compiled [7]. To remove information "noise" associated with the presence of different-height, mainly herbaceous vegetation, the original resolution was reduced to 0.5 m, which made it possible to more accurately identify the features of the microrelief itself.

Mapping and analysis of the DEM was carried out using ArcGis software. Maps of the areas were created at a standard scale (1:10,000). An individual projection was selected for the coordinate grid (PROJCRS ["ProjWiz_Custom_Lambert_Azimuthal", BASEGEOGCRS ["WGS 84", DATUM ["World Geodetic System 1984", ELLIPSOID ["WGS 84",6378137,298.257223563, LENGTHUNIT["metre",1]], ID ["EPSG",6326]]).

III. Results

The distribution of the test areas by elevation marks is illustrated in Fig. 4 and Table 1



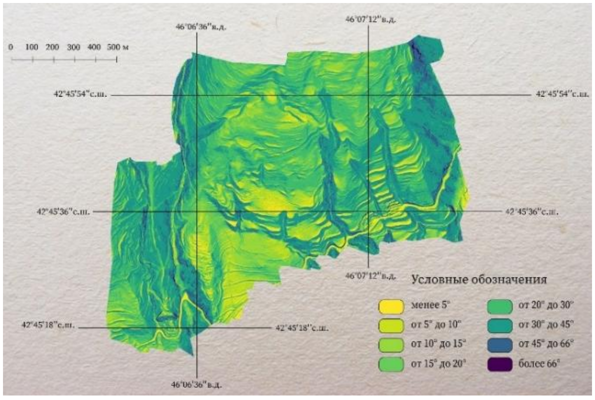
a) section of the southern macroslope *b) section of the northern macroslope*

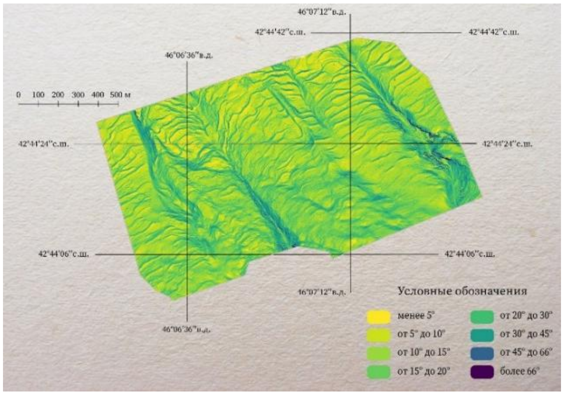
Figure 4: *Hypsometric map of the southern (a) and northern (b) macroslopes of the Makazhoy basin*

Table 1: *Distribution of the test site area by elevation marks*

Height, meters	Southern macroslope		Northern macroslope	
	hectare	%	hectare	%
1700-1750	0,7	0,4		
1750-1800	9,6	5,7		
1800-1850	22,1	13,1	0,4	0,2
1850-1900	27,2	16,0	17,0	10,1
1900-1950	22,8	13,5	35,3	21,0
1950-2000	24,4	14,4	37,5	22,3
2000-2050	20,7	12,2	36,9	22,0
2050-2100	18,5	10,9	25,8	15,4
2100-2150	14,3	8,4	14,7	8,8
2150-2200	9,2	5,4	0,3	0,2
TOTAL	169,4	100,0	168,0	100,0

As can be seen from the presented data, there is a well-defined asymmetry in terms of the distribution of areas by elevation marks. Thus, on the southern macroslope, where the range of elevations is almost 100 m greater than on the northern one, the main territories are confined to the heights of 1800-2000 m, after which the areas of territories located in the highlands begin to shrink. As for the northern macroslope, here the heights of 1900-2050 m account for more than 65% of the territory, and at the same time the most elevated areas are more widespread compared to those occupying the lowest hypsometric levels. It is also clearly visible that the northern macroslope is much more gentle than the southern one, which well illustrates the distribution of the territory by slope steepness. The change in steepness on the slopes of the Makazhoyskaya Depression test sites is illustrated by Fig. 5 and Table 2.





a) section of the southern macroslope *b) section of the northern macroslope*

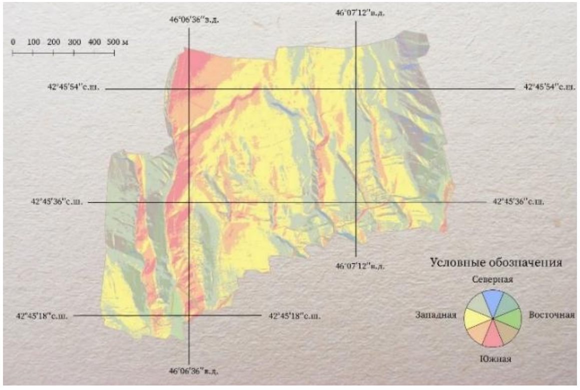
Figure 5: *Map of the steepness of the slopes of the southern and northern macroslopes of the Makazhoy basin*

The presented data indicate that the distribution pattern of steepness on the macroslopes is generally opposite. The steepest (more than 45°) and the most gentle (less than 5°) slopes occupy the smallest areas on both slopes. On the northern macroslope, where the regenerative livestock farming site is located, slopes with a steepness of 10-15◎ are most widely represented (29.2°), and steeper (15-20°) and gentler (5-10°) slopes are also quite widely represented (21.3 and 20.3%, respectively). As the steepness increases, the area of the slopes decreases. As for the southern macroslope, a gradual increase in the area of slopes up to a steepness of 30-45° is noted here, which account for 33.3%. The larger area of steep slopes on the southern macroslope is explained by the large amount of solar radiation coming here and contributing to more active geomorphological processes. In particular, here, compared to the area located on the northern macroslope, erosional relief forms are presented more widely, aerosional cuts, to which the steepest slopes are confined, have become more widespread.

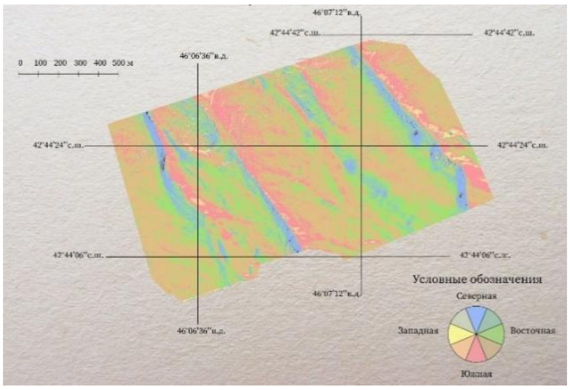
Table 2: *Distribution of the test site area depending on the steepness of the slopes*

Slope, degrees	Southern macroslope		Northern macroslope	
	km ^{2}	%	km ^{2}	%
0-5	4,2	2,5	8,0	4,7
5-10	11,2	6,6	34,1	20,3
10-15	17,0	10,0	49,0	29,2
15-20	23,3	13,8	35,7	21,3
20-30	46,5	27,4	31,5	18,8
30-45	56,4	33,3	8,6	5,1
45-66	10,3	6,1	0,9	0,5
66 и более	0,4	0,2	0,2	0,1
TOTAL	169,4	100,0	168,0	100,0

Distribution of slopes depending on their exposure on the test sites of the Makazhoyskaya depression is illustrated in Fig. 6 and Table 3.



a) section of the southern macroslope



b) section of the northern macroslope

Figure 6: *Map of the exposure of the slopes of the southern and northern macroslopes of the Makazhoy basin*

Table 3: *Distribution of the test site area depending on the slope exposure*

Exposition	Southern macroslope		Northern macroslope	
	га	%	га	%
North	0,4	0,2	37,1	22,1
Northeast	2,6	1,5	10,2	6,1
East	24,1	14,2	2,2	1,3
Southeast	44,8	26,4	1,7	1,0
South	60	35,4	2,2	1,3
Southwest	25,3	14,9	5,7	3,4
West	11	6,5	24,7	14,7
Northwest	1,2	0,7	84,2	50,1
TOTAL	169,4	100,0	168,0	100,0

As in the case of slope steepness, the opposite pattern of distribution of this parameter is generally observed. Thus, due to the fact that the carbon polygon area is confined to the northern macroslope of the Makazhoyskaya Basin, the slopes of the north-western (50.1%), northern (22.1%)

and western (14.7%) are most widely represented here, i.e. 86.9% of the entire area of the area. In the second test area, the southern (35.4%) and south-eastern (26.4%) are most widely represented, i.e. more than 60% of the territory. Nearby areas have north-western and eastern slopes (about 14%). That is, the test sites in these areas of the Makazhoyskaya Basin are located on its north-western and south-eastern mesoslopes.

The provided maps, created on the basis of the DEM, also allowed to compile a map of terraces, which were created by the population to intensify mountain nature management. In terms of relief, terraces are sections of mountain slopes, the steepness of which is reduced by creating retaining walls. As a result, these flattened sections can be determined quite well on the basis of the digital elevation model.

Terrace mapping is based on 3 groups of methods: manual, semi-automatic and automatic. Preliminary analysis of the initial data showed that the most accurate result is obtained by combining manual and semi-automatic methods. During the preliminary analysis, the semi-automatic method with vectorization using preliminary selection of terraces using manual tracing was recognized as the most accurate. This method combines both the best accuracy and the time spent on vectorization with the supporting requirements for the data.

The results of terrace selection based on the DEM within the Makazhoy Basin are illustrated in Fig. 7.

The calculations showed that with a total area of the southern macroslope of the Makazhoy Basin of 169.4 hectares, the area of the terraces is 44.1 hectares, or 26% of the territory. The test site of the regenerative livestock farming site of the A.A. Kadyrov CheSU, confined to the northern macroslope of the Makazhoy Basin, has an area of 168.0 hectares, of which the terraces occupy 76.6 hectares, or 46%.

The maps clearly show that only slopes with minimal steepness were subjected to terracing. To increase the efficiency of agricultural management, it was necessary to create single, largest-area terrace sections, which was achieved to the maximum extent on the northern macroslope. As for the southern macroslope, the fragmentation and mosaic nature of the terraces is quite well expressed here, which is expressed in the presence of a fairly large number of small fragments, most widely represented in the eastern part of the test site. The high degree of agricultural development of the territory is confirmed by the presence of a large number of ruins reflected on late Soviet topographic maps (Fig. 8), reflecting the state of the area in the 1980s. They clearly show that all areas of the basin were intensively developed. The southern macroslope was used to the greatest extent for construction and residence, while the northern slope, apparently, was used for hayfields and pastures due to the better productivity of pastures, since the settlements here are confined to the part that adjoins the Akhket River.

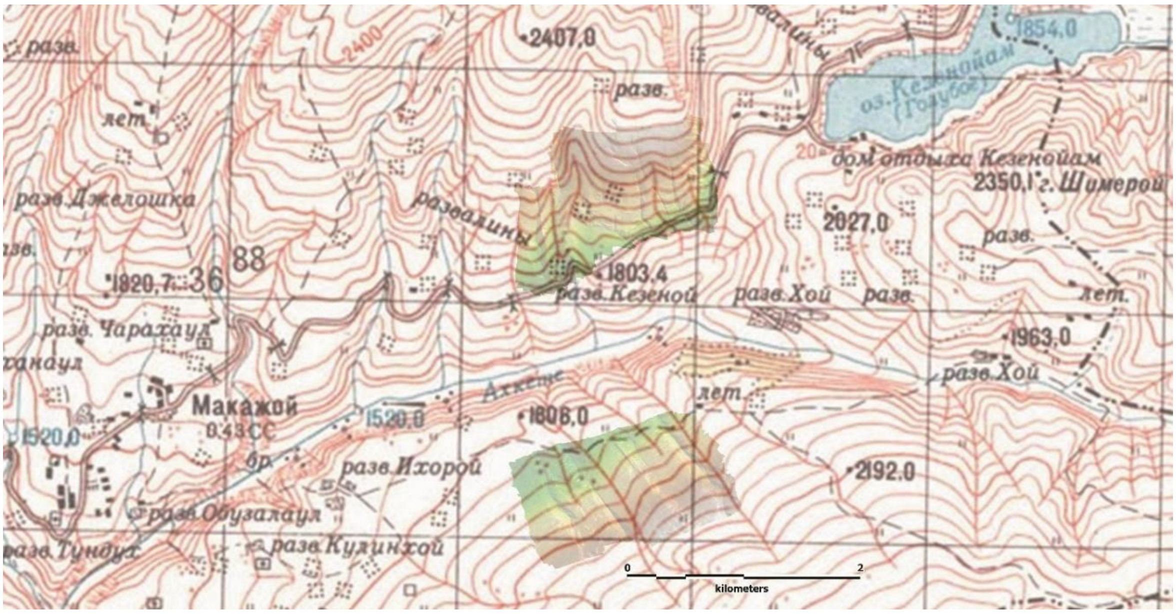

Figure 8: *Fragment of a topographic map illustrating the historical aspect of the degree of economic development of the territory*

IV. Discussion

The conducted study allowed to conduct a comparative analysis of the relief of the southern and northern macroslopes of the Makazhoy Basin based on a series of large-scale morphometric maps obtained on the basis of a digital elevation model. The latter was created by airborne laser scanning during the survey from a unmanned aerial vehicles.

A comparative analysis of the distribution of morphometric indicators (hypsometry, steepness and slope exposure) revealed that on test sites comparable in absolute height and occupied area, the northern macroslopes of the Makazhoy Basin are characterized by generally more gentle slopes. It is this fact that makes it possible to suggest that this parameter is decisive for their terracing in order to intensify economic use. This fact is confirmed by the fact that terraces on the northern macroslope occupy 46%, while on the southern one they are almost twice as small (26%). The created digital elevation models allow for a quantitative assessment of the processes of formation of phytomass reserves and its products at the local level, and in combination with microclimatic observation data, they can serve as a basis for GIS modeling of productivity and the possibility of developing optimal loads on pastures.

The research was conducted as part of the implementation of a state assignment *FEGS-2023-0008.*

Abstract

The COVID-19 pandemic has had a significant impact on global environmental change, primarily through the reduction of greenhouse gas emissions and air pollution due to the sharp decline in economic activity, particularly in the transportation and industrial sectors. While these changes brought temporary environmental improvements, such as better air quality and reduced water pollution, they did not offset long-term environmental challenges. The pandemic's effects on human health have been mixed: on one hand, improved air quality may have reduced respiratory illness-related morbidity, while on the other hand, the economic downturn and disruptions in healthcare services negatively affected public health. The long-term implications of the pandemic highlight the need for a transition toward more sustainable economic activities and improved natural resource management to mitigate future health and environmental risks.

Keywords: greenhouse gas emissions, air pollution, human health, sustainable development, climate change, air quality, economic downturn

I. Introduction

The COVID-19 pandemic and the associated social restrictions such as isolation and travel restrictions have impacted various areas of society, as well as people's work and personal lives. The impact of the pandemic has varied depending on the sector of work, socio-economic situation and other factors. For example, depending on the requirements for physical presence in the workplace and the availability of remote working options, people have experienced different changes in their daily lives.

At the global level, the COVID-19 pandemic has exposed systemic weaknesses in infrastructures, supply chains, government preparedness and response, as well as human resources and public health systems. The pandemic has challenged public health officials and health system managers to maintain a coherent narrative of measures to control the spread of COVID-19. Among other challenges encountered in the fight against the virus, it became apparent that many health facilities were ill-equipped and unprepared for the influx of patients, and had insufficient medical and epidemiological training to adequately care for patients. Overall, public health systems were unprepared to deal with a new viral pathogen that was rapidly spreading across the world, as containment measures were not rigorous enough and were not effectively implemented at the most critical time.

More than two years after the emergence of SARS-CoV-2, it has become clear that collaboration in information sharing between governments and health care providers, as well as clear and timely communication with the public, are critical to slowing the spread of the disease and preventing a resurgence of the pandemic. However, it is still unclear whether health measures in any country have adapted to the possibility of another outbreak.

Part of the recovery from the pandemic requires reorganizing public health systems to be better prepared to manage new outbreaks of diseases that have overburdened the traditional hospital system and significantly reduced the quality and volume of health care. Thus, public health systems must be rebuilt to effectively and competently manage emerging infectious diseases and are framed around five key activities: (1) governance, (2) protection, (3) containment through transmission control and suppression, (4) information, and (5) support (see Figure 1).The COVID-19 pandemic has put immense pressure on global economic and healthcare systems, underscoring the extent of global interconnections and the critical need for preparedness against global health threats (fig.1). Current efforts are largely centered on pandemic response, including developing treatments and vaccines. However, other pressing health threats, driven by human activities—such as climate change, pollution, urbanization, and unsustainable consumption—may seem less urgent. These factors have caused significant environmental disruption and biodiversity loss. Addressing the pandemic in isolation from these issues, through measures like increased use of disposable materials, reduced public transport, or subsidizing polluting industries, may offer short-term economic and health benefits but would undermine long-term goals for human health and sustainability. Climate change and other environmental stressors, along with their impacts on human and ecosystem health, remain ongoing challenges. The COVID-19 crisis highlights the links between environmental changes and the emergence of infectious diseases, emphasizing the urgent need for prevention, as controlling pandemics in a globalized world has proven difficult. This situation calls for a planetary health perspective in governance and research, adopting interdisciplinary, transdisciplinary, and cross-sectoral approaches.

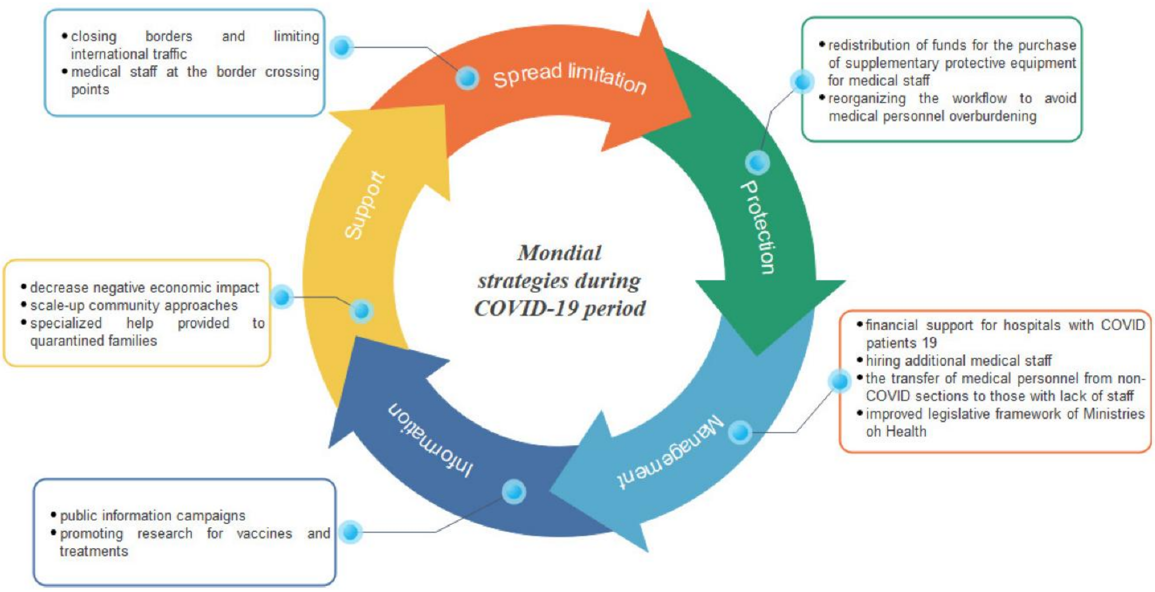

Figure 1: *Mondial strategies during C19, describing five measures that focus on redesigning public health care systems to better manage future pandemic events*

Compounding the response to COVID-19 are concurrent global challenges such as heat waves, wildfires, locust swarms in East Africa, droughts, and the severe 2020 cyclone season. Additionally, the pandemic itself is likely to impede optimal responses to these threats, overburdening under-resourced public health systems, complicating evacuations and emergency measures, and fostering the spread of misinformation and conspiracy theories. The pandemic and environmental health issues are deeply intertwined, and we argue that only an integrated global approach that simultaneously addresses infectious diseases and other environmental threats will lead to sustainable solutions and policies to safeguard both human and ecosystem health for current and future generations. In this paper, we outline the key findings of this work.

II. Methods

Improving our understanding of the ecological and behavioral drivers behind the emergence and spread of coronaviruses is crucial. While the zoonotic origin of SARS-CoV-2 has been well-established, a direct connection between the viral variants found in bats, pangolins, and humans remains unidentified, including the intermediary host(s) that transmitted the virus to humans. Understanding the ecology and epidemiology of COVID-19 also involves investigating the genetic basis of host susceptibility, whether in animal reservoirs or human populations. Key research questions include the impact of ecosystem changes—deforestation, land use, infrastructure development, and urbanization—on human-wildlife interactions, and the subsequent increased risk of zoonotic disease spillover. It is vital to determine the extent to which habitat destruction and human activities (such as farming, hunting, and wildlife trade) have contributed to recent zoonotic disease outbreaks, particularly SARS-CoV-2. In the context of climate change, the role of biodiversity loss in disease emergence also requires more in-depth investigation.

Advances in methods and tools are also necessary. For example, ecological health observatories could help analyze the social-ecological dynamics of SARS-CoV-2 and track its spatial and temporal patterns across different ecosystems (wild and domestic animals, air, and water) in both urban and rural environments. Viral genome screening of wildlife (through metagenomics) and the creation of open-access databases are needed to trace transmission pathways and viral evolution within the intermediary hosts of SARS-CoV-2. These efforts will also be critical for managing future emerging viruses. Pandemic modeling has proven essential for informed decision-making during COVID-19, and improving data integration and processing, as well as enhancing modeling capacities worldwide, is crucial. This includes models that account for climate conditions affecting viral transmissibility and models that describe human interactions to estimate effective contact rates. Thus, these models must incorporate epidemiological, demographic, ecological, evolutionary, climatic, social, and cultural data, as these are all key factors in disease evolution.

Research will require interdisciplinary collaboration across fields such as microbiology, medicine, epidemiology, ecology, environmental and evolutionary sciences, veterinary science, agriculture, social sciences, urban planning, mobility studies, anthropology, and behavioral economics. These data will be necessary to both build and validate models of disease emergence and transmission, and integrative approaches that encompass human activities and health status should be prioritized.

The combined effects of infectious diseases and environmental stressors are a major concern. COVID-19 severity has been strongly linked to age and comorbidities, including respiratory, cardiovascular, and metabolic diseases, as well as obesity, conditions partly caused by exposure to environmental stressors such as poor urban planning, unhealthy food environments, air pollution, and chemical toxicants. Better understanding of how pollutants impact immune and cardiometabolic health is essential for identifying population-level vulnerabilities and exacerbating factors. COVID-19 has disproportionately impacted low-income and minority groups, underscoring the role of socioeconomic factors in both exposure to and vulnerability to the virus.

Coordinating existing cohort studies across Europe is a key step, along with the Europe-wide development of tools and models to better assess and predict the health, social, and environmental determinants of COVID-19. The pandemic has highlighted the deep interconnections between infectious and non-communicable diseases, with the latter exacerbating the severity of the former.

It is therefore crucial to explore how viral infections interact with environmental factors of chronic diseases, such as chemical exposure, air pollution, climate change, and socioeconomic conditions.

For example, more research is needed on the dual role of indoor air quality in both environmental contamination and viral spread, as well as innovative solutions for mitigation, such as air purification technologies. Additionally, exposure to wood smoke at relatively low levels has been linked to suppressed respiratory immunity, increasing susceptibility to infections and lung diseases—a concern that is particularly relevant given the energy poverty exacerbated by recent financial crises. Similarly, the risks and benefits of spending time in parks, green spaces, and blue spaces (water bodies) need further investigation.

III. Results

The World Health Organization (WHO) officially declared COVID-19 a pandemic on March 11, 2020. In response, many countries implemented quarantine, isolation, and lockdown measures as part of public health strategies to limit the spread of the virus. While these actions were necessary to control the outbreak, they also led to severe economic downturns and significant changes in social behavior. However, this unprecedented global event also had unexpected positive effects on planetary health. The widespread shutdown of industries, travel restrictions, and lockdowns resulted in several environmental benefits, particularly due to the reduction of human-caused pollution.

The World Health Organization (WHO) reported that the SARS-CoV-2 virus can be transmitted through blood, stool, saliva, and respiration, making the availability of personal protective equipment (PPE) for healthcare workers a critical part of treatment, containment, and the health of the workers themselves. In the general public, where precautions were less strict, the disease spread widely. Testing laboratories were vital early in the pandemic and continue to play a crucial role in documenting the spread of COVID-19. While testing is a post hoc measure, it reveals the prevalence of infection, providing valuable epidemiological data and helping coordinate healthcare needs for infected individuals. Rapid identification and diagnosis of COVID-19 cases can lead to quick treatment for patients, with workflows adapting to evolving care procedures and standards for infection detection.

Generally, standard protocols for handling COVID-19 cases involved transferring patients to COVID-19 containment areas. However, the specifics of these protocols were not thoroughly investigated, making it challenging to assert the existence of a cohesive global protocol. Although public health authorities were typically notified of cases, tracking and tracing patient contacts with family members and others proved burdensome, limiting population-level containment approaches. While the majority of cases globally did not require hospitalization, patients treated at home still posed health risks, as individuals often came into contact with others due to the urban environments where most people live.

Asymptomatic individuals, who were often untested, presented a significant challenge during the pandemic; therefore, comprehensive testing strategies emerged as the best solution to mitigate the spread of the coronavirus. Asymptomatic transmission of SARS-CoV-2 is considered a major obstacle in controlling the COVID-19 pandemic. Consequently, continuous testing of staff who attend to vulnerable populations and those in need of care is essential. The use of rapid antigen tests for SARS-CoV-2 has streamlined emergency departments and facilitated public access to home-based testing methods, although false negatives are a possibility. Despite these minor drawbacks, the advantages of rapid tests and at-home testing kits are crucial in tracking the virus's spread.

According to globally established regulations, testing and metagenomics laboratories involved in the detection and sequencing of the SARS-CoV-2 virus must be managed by trained staff or experts, who are required to comply with established protocols (mainly separating input and output flows) and be equipped with nucleic acid extractors, RT-PCR devices, ultra-low freezers, UV lamps for decontamination, and other disinfection equipment, as well as automatic pipettes (robots) and contamination-free consumables.

Unfortunately, the COVID-19 pandemic has claimed many lives. However, it has also prompted a reevaluation of medical systems worldwide. The reorganization of emergency departments was beneficial, and many of the models implemented remain relevant even post-pandemic, allowing for better-organized workflows, quicker interventions, and increased medical advice sought by patients with minor needs via telephone or telemedicine.

More than any other ward, the emergency department was primarily engaged with COVID-19 cases. Most medical staff were reassigned to this department, receiving training and remaining on standby. Emergency rooms often experienced overcrowding. The organization of medical processes using a color-coded system helped alleviate the situation. For example, in Italy, a heavily impacted country, the emergency department was organized by color based on severity: white, green, yellow, and red. Red indicated immediate access, orange allowed access within 15 minutes, blue within 60 minutes, green within 120 minutes, and white within 240 minutes. This color-coding system was later adopted by hospitals in various parts of the world, representing a model of good practice.

Rapid detection of COVID-19 was crucial for patient treatment and minimizing the risk of transmission. In addition to continuous PCR testing, doctors discovered alternative methods for identifying the disease, such as ultrasound or symptom assessment. In all countries affected by the pandemic, emergency departments were supplemented with PCR equipment, CT scanners, and ICU units, either through redistribution from their own units or through donations from more developed hospitals or states assisting severely affected countries.

Funding from industry, academia, government agencies, and regulatory bodies has helped emergency departments worldwide, facilitating easier access for sick individuals to medical care and treatment. Protective equipment for emergency department staff was enhanced (including coveralls, high-protection masks, gloves, face shields, and goggles), and workflows were digitized to ensure immediate connections between reception areas and care and treatment zones. Critically ill patients were isolated in airborne infection isolation rooms or negative pressure isolation rooms with HEPA filtration of recirculated air.

IV. Discussion

Much of the work performed by dermatologists underwent significant reorganization during the COVID-19 pandemic. Many dermatologists were reassigned to COVID-19 treatment facilities, resulting in non-essential cases being sidelined to focus on critical patient care. Consequently, hospitalizations for non-medical emergencies ceased, and routine consultations transitioned to telemedicine. In instances where face-to-face consultations were essential, particularly for conditions like melanoma that require early surgical intervention, procedures were adjusted to protect staff from COVID-19 exposure. Unlike in some countries where workflow reorganization facilitated urgent dermatological treatments, many low- and middle-income countries faced challenges in addressing conditions requiring emergency care, such as solid tumors and metastatic diseases.

In dermatological emergencies, triage is essential. Dermatological consultations typically cannot occur from a distance of less than 25 cm, particularly for dermoscopies or other interventions. When patient interactions occurred, staff were required to wear PPE and adhere to strict decontamination protocols before and after contact, especially after handling contaminated surfaces or body fluids. The European Task Force on Atopic Dermatitis recommended the continuation of immune-modulating treatments, urging strict adherence to hygiene protocols, including the use of non-irritating cleansing agents and moisturizers after each application.

Similar to many hospital wards, orthopedic departments underwent complete restructuring. Non-emergency interventions were postponed to prioritize major emergency and oncological cases. Mild cases that would usually be treated in inpatient or outpatient settings were also deferred until safe conditions were restored following the pandemic. However, patients such as pregnant women, immunocompromised individuals, or those over 60 years of age continued to be classified as medical emergencies. Medical staff utilized PPE during patient intakes and procedures, with workflows adapted due to the challenges of accurately assessing patients' conditions following initial consultations. Continuous monitoring was necessary for health changes, considering potential COVID-19 symptoms like fever, loss of taste or smell, respiratory or gastrointestinal issues, and cardiac irregularities. Suspected nasopharyngeal samples were collected for PCR testing and processed in designated areas while awaiting results. Patients who tested positive for COVID-19 and presented as medical emergencies were transferred to specialized containment areas for surgical procedures.

The number of medical personnel allowed in operating rooms was limited, and procedures that could generate aerosols were avoided. Treatment equipment for COVID-19 patients, such as monitors and ultrasound devices, had to be protected from contamination and easily cleaned to minimize risks. Postoperative routines were adjusted to maximum capacities, and where possible, portable radiography equipment was used and disinfected immediately after use. Dressings and splints that could be easily changed were primarily utilized for postoperative care.

The COVID-19 pandemic posed significant risks for over 100 million pregnant women worldwide. Due to suppressed immunity, these women are at increased risk of moderate to severe infections that can also affect their fetuses. Pregnant women with COVID-19 face heightened risks of miscarriage, premature birth, and preeclampsia. Fetuses are also at increased risk of mortality and requiring intensive care. Routine screening for COVID-19 is crucial for this population. Pregnant women who contracted the virus but exhibited no respiratory symptoms were advised to quarantine at home while maintaining communication with their primary care providers.

Continuous health monitoring of pregnant women is vital, necessitating regular testing and blood tests for various important parameters. In heavily impacted areas, initial consultations were suggested to occur at home, with subsequent hospital visits to minimize unnecessary exposure to patients. Typically, patients would be hospitalized for 1-2 days before giving birth, but during the pandemic, contact with medical facilities was limited to ensure safety for both mother and fetus. This change posed scheduling challenges for hospitals and patients.

During cesarean sections, epidural anesthesia is typically administered, but the use of nitrous oxide was minimized due to the risk of aerosol generation, which could facilitate virus spread. Breastfeeding is encouraged for women infected with COVID-19, as studies indicate that both IgG and IgM antibodies can be transmitted through breast milk. Antibodies are present in breast milk as early as two weeks post-vaccination. To mitigate contamination risks, visits by outsiders were prohibited, and online communication became the primary means of connecting with family and friends. Before discharge, both mothers and newborns underwent COVID-19 testing, and they could only leave the hospital after receiving negative test results.

The pandemic also significantly impacted pediatric healthcare. Initially, the number of COVID-19 cases among children was relatively low; however, with the emergence of new SARS-CoV-2 variants, children became increasingly affected. Fortunately, symptoms in children tend to be milder, including fever, dry cough, nasal congestion, abdominal discomfort, or diarrhea, with many remaining asymptomatic. Nonetheless, there have been instances requiring pediatric emergency care. Hospitals prepared for pediatric emergencies, particularly in infectious disease wards.

Most children needing emergency care faced moderate to severe respiratory infections, such as influenza and bronchiolitis, meningitis, sepsis, osteomyelitis, and asthma. The Omicron variant, while more contagious among children, has resulted in less severe outcomes compared to the Delta variant, with lower rates of hospitalization, ICU utilization, and mechanical ventilation.

Although environmental and health professionals have an expert understanding of the spread of infectious pathogens and the potential for zoonotic pandemics, the shock of COVID-19 has been particularly profound. The confirmation of the zoonotic origin of the virus, its survivability in air, water, and surfaces, and its modes of transmission have clearly demonstrated that the COVID-19 pandemic is a global emergency based on the link between the environment and human health. The environment has played a key role in the emergence and spread of SARS-CoV-2, as well as in the societal response to this emergency.

National and subnational environmental and health structures have been affected in almost every aspect of their work. For experts who (at least in developed countries) have long focused on understanding and managing the environmental aspects of noncommunicable diseases, it has come as a surprise that infectious diseases have once again come to the fore. The pandemic has also demonstrated the importance of understanding the impact of the environment on mental health in the context of isolation and restrictions, and the need to adapt homes and public spaces to new conditions.

Before the pandemic, environmental and health professionals realized that their work transcends traditional understandings of space and time. Climate change and its impacts have shown that the key function of public authorities in this area - ensuring a safe and healthy environment - must take into account the impact of economic and social factors, as well as human activities, on ecological systems. Moreover, work at the national and subnational levels must now include concern for the environment and health of people beyond these territories. COVID-19 has once again confirmed this need.

It is important to note that climate factors and pandemics, although different phenomena, are interrelated in their origins and require the creation of societal resilience. The working hypothesis should take into account the possibility of the simultaneous occurrence of pandemics, climate events and disasters in the future. The COVID-19 pandemic has not only exposed societal resilience issues that will be exacerbated by climate change, but also exposed significant vulnerabilities across a range of sectors.

The pandemic has also exacerbated social inequalities. People with low incomes, chronic illnesses, the elderly, and other vulnerable groups were at greater risk of infection and severe consequences. One clear finding was that knowledge workers, who tend to have higher incomes, were able to work remotely, avoiding the risk of infection. At the same time, low-income workers often faced higher risks, as they were forced to be in the workplace and use public transport. This policy brief provides a high-level picture of the environmental and health impacts of the COVID-19 pandemic, without going into depth on specific issues or topics. Although WHO has declared the COVID-19 pandemic no longer a public health emergency of international concern, its impacts will be felt for a long time. Moreover, the COVID-19 literature is constantly evolving, expanding the evidence base.

The analysis presented here begins with a No COVID Base scenario representing expected development patterns in a world without the pandemic. To simulate this we rely on economic growth rates produced just prior to the pandemic in the World Economic Outlook (WEO). We apply growth rates from this report for 2019–2025 and then use IFs endogenous growth projections through 2050. For this scenario we maintain 2017 country Gini-index values through 2050. As noted previously, this scenario produces similar results to other medium-variant forecasts prior to the outbreak. We compare this No COVID Base scenario with the COVID Base scenario. This scenario simulates the effect of COVID-19 by including WEO growth projections published for the years 2021–2023. From 2023–2050 we also rely on IFs endogenous growth projections for this scenario and keep country-level income inequality values flat across time. We compare these two scenarios with six alternative scenarios that frame uncertainty by varying GDP growth and income inequality. We vary GDP growth by 1.5 percentage points for 2022 around the COVID-Base values and then converge these to the COVID Base growth trajectory by 2025. The 1.5 percentage points variation is a high-end assumption that falls within the standard variation across world GDP growth rates from the WEO during the COVID-19 period (~1.6%), and the mean difference across countries in GDP growth rates comparing the World Bank Global Economic Prospects [85] and the IMF WEO April 2021 release (~1.6%).

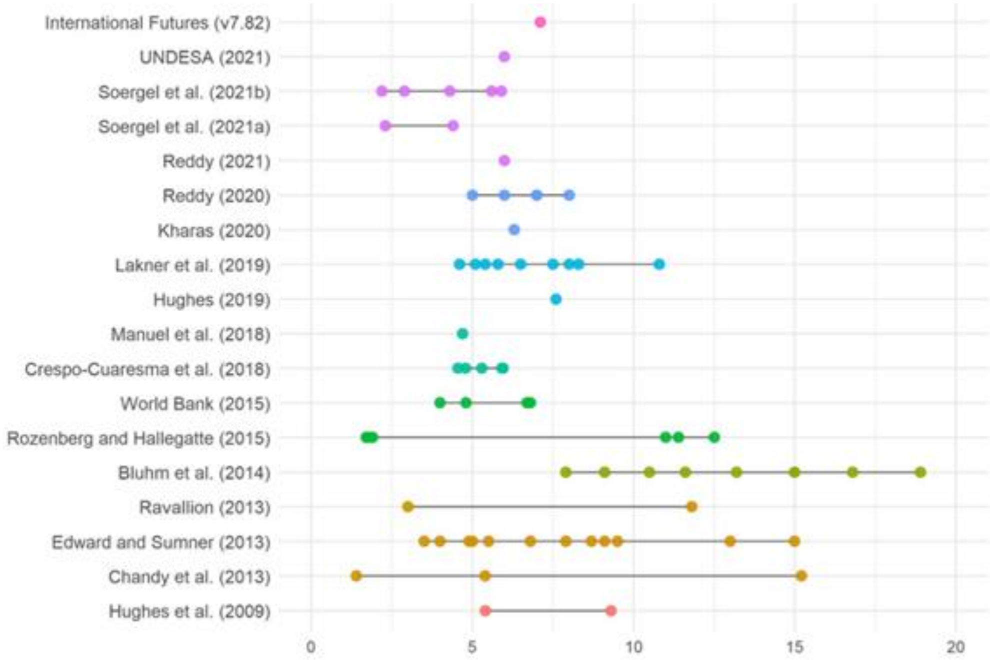

Figure 2: *Previous projections of extreme poverty levels summary that do not account for COVID-19*

This policy brief is based on a "rapid review of policy papers" (WHO Regional Office for Europe, 2023), which reviews high-quality studies published from early 2020 to early 2023. This review is structured similarly to this policy brief and provides more detailed information on the topics discussed. It also aims to facilitate access to policy papers and primary research.

The published and unpublished reviews highlight the desire for change and acknowledge the urgency of this change. The COVID-19 pandemic has caused significant disruption, and some survey results suggest that it has created a sense of urgency for change that goes beyond the academic and policy circles that provided the analyses discussed.

People are now more informed and have a better understanding of how their experiences of the pandemic and the impacts of climate change relate to their health, well-being, and ultimately the survival of humanity. Institutions and sectors of society have clearly demonstrated a lack of resilience.

Abstract

The mountainous regions of the Earth have significant elevation differences even on small areas of the earth's surface, which is the main reason for the characteristic combination of natural conditions in these regions. This includes height as a leading factor, resulting in relief and a corresponding complex of natural components. All other components of development in these areas will be radically different from those in nearby plains, and the conditions of existence for the population will also be characteristic of these territories. These conditions affect lifestyle, occupation, and health. Altitude is most clearly traced in the variability of hydroclimatic, soil-biological, and landscape components vertically. As altitude and climatic components directly affect agricultural specialization, it is important to consider these factors when planning agricultural activities in mountainous areas. There is a change in the direction of reducing the duration of the vegetation period for plants. Agriculture is associated with growing cold-resistant plants, while heat-loving plants are grown on the plains and their growing season is shorter. The physical and geographical challenges of highlands involve determining the limits of disturbance or barrier that can cause instability, as well as forecasting the development of weak components. It is necessary to identify processes that affect the development of mountains. These include altitude, topography, climate, and weathering, which together determine the stability of natural complexes in highlands.

Keywords: mountainous areas, natural components, safety margin

I. Introduction

Mountainous countries are characterized by an unusually rich, diverse, and variegated vegetation cover. This is due to a variety of habitats and environmental conditions, including changes in temperature with altitude, lighting conditions depending on slope exposure, and humidification conditions depending on relief. Because of these factors, mountain biota surpasses lowland territories in terms of biodiversity. A person should be aware of the characteristics of the altitude zone because the natural nature of plains has been changed by agriculture. Mountains will remain in their natural state for a long time and their landscapes will influence nature management and development. These factors are necessary for the sustainable use of mountain resources. The study of mountain natural complexes and their patterns is important for understanding the ecological processes that occur there [1,2]. Distribution is impossible without a broad geological analysis, linking vegetation with the surrounding geographic landscape. Precisely because mountains with their rich plant, animal, aquatic, and fossil wealth, located in relatively small spaces, have been and remain, on an ever-increasing scale, suppliers of resources for lowland civilizations. Summer grazing, logging, mining, engineering, construction of dams, roads, and much more are areas of exploitation of mountains for the prosperity of the plains.

II. Methods

The 21st century, the century of mountains, is the United Nations' forecast for the future of humanity. It has been stated that in the near future, mountains will determine the quality of life for all of humanity. According to the prediction, in the near future, mountains will determine the quality of life for all mankind, despite the fact that they occupy only 1/5 of the Earth's surface and only 10% of the world's population lives in mountainous areas. Mountains contain a vast potential of natural resources, including hydropower, which is being almost untapped by humans. This makes them a storehouse of the Earth's interior that has been preserved from human interference. We can say that mountainous areas have a unique lifestyle, mentality, and cultural and biological diversity that seems to be frozen in time.

Only with a new approach to assessing mountains and their potential for providing natural and biological resources can we transition to a sustainable development policy for mountain ecosystems. this consideration of the issue will allow us to include the potential of mountain territories in the parameters of regional wealth. The degradation or destruction of mountains is still a major concern today [3, 4].

Despite this, mountains remain some of the most ecologically prosperous regions of the planet, where the STR (Scientific and Technical Revolution) has not taken over yet. Mountain regions are unique in many ways. They lack industrial enterprises with their harmful emissions and drains. Asphalt pavements have not sealed off the soil, allowing geochemical processes to continue. Vehicles are fewer, and the population is smaller than in nearby plains.

All of this does not imply that there are no challenges in mountainous regions. One of the issues is the expansion of grazing areas in the alpine meadow zone and the consequent depletion of flora and fauna in these areas.

Another, not less significant aspect, is the melting of glaciers in the snow zone due to a global warming.

If we talk about alpine meadows, this is a highly vulnerable ecosystem. In order to preserve this unique ecosystem, it is essential to immediately ban the grazing of domestic animals in this area. Domestic animals, such as hoofed mammals, can significantly affect the structure and productivity of plant communities in alpine meadows. It should be noted that the number of pets may increase. Wild animals also have an impact on the vegetation of mountain meadows.
Unregulated and haphazard use of pastures is prohibited by law given the current situation, which is one of the most pressing issues today [5,6].

One of the goals of comprehensive geographical research is to assess the natural resource potential of a territory, primarily in mountainous areas due to their vulnerability. Due to the potential resources of the territory the environment is not taken into account, and this leads to a deterioration in environmental conditions.

III. Results

The peculiarity of mountainous areas is the specific distribution and transformation of solar energy. The amount of solar radiation in the mountains increases in proportion to the increase in altitude, elevation difference, and steepness of the slopes.

The rugged terrain creates an absence of large flat areas in the mountains, leading to high activity of slope processes and a concentration of vegetation in particular local areas.

We can identify the main causes of the vulnerability and extreme instability of mountain geosystems:

1. The geosystems in the highlands have relatively simple, direct, and rigid connections. This is because natural complexes develop in rugged terrain, where parameters such as altitude and associated temperature are important. This means that they are dependent on external influences.

2. Ecological relations in mountainous areas are disproportionate. This is due to the dominance of abiotic environmental factors, such as light, temperature, and humidity. These external factors are more influential than internal factors in mountainous ecosystems.

An ecosystem is a system composed of interrelated and interdependent parts that interact through the exchange of materials, energy, and information. As a result, internal connections within the system are more stable and help maintain the overall structure of the ecosystem. This is due to the inherent dynamism of mountainous environments, which can lead to changes in the composition and function of an ecosystem over time.

3. Inclined surfaces in mountainous areas can support various types of life, including plants, animals, and microorganisms. Provided that the flow of matter and energy follows a downward gradient, the physical and energetic properties of natural systems are closely interrelated and cannot exist independently of each other in natural environments. These include talus and mudflow deposits, which have an oval shape. Consequently, it can be observed that the boundaries between ecological systems will be fluid and will depend largely on climate change and human activities [7,8].

IV. Discussion

The physiographical issues of highland areas are associated with the need to determine the limit of disturbance or barrier, beyond which their stability is compromised. This involves identifying problems in the landscapes of the mountainous meadow zone and forecasting the development of weaker components. It is essential to identify the processes that influence the development of mountain areas. These include, primarily, altitude, topography, climate, weathering, and solar radiation. Together, these factors determine the safety margin for natural complexes in highlands.

Physiographical issues related to high-altitude zones can be grouped according to their factors of occurrence:

1. The ones related to the distinct mountainous terrain and the inclination of the mountains include landslides, debris slides, rock falls, mudflows, and avalanches.

2. The ones caused by climate and natural conditions, such as fog, precipitation in the form of rain and snow, thunderstorms, and wind, may also contribute to physiographical issues.

3. The ones caused by the anthropogenic activities

As previously noted, mountains possess a significant potential for natural resources, contributing to a quarter of the total biological diversity on land. This diverse range of plant and animal species can be attributed to several factors, with the most prominent being the extensive variety of climatic conditions over short distances and a diverse array of habitats. Consequently, it is essential to recognize that the conservation of mountain biodiversity is becoming an essential component of the sustainable development agenda for mountainous regions. Addressing this pressing issue necessitates socio-economic development in mountainous areas.

Therefore, one of the most significant challenges in the sustainable development of mountainous regions continues to be the preservation of landscapes and biological diversity, as well as the establishment of a natural and ecological foundation.

The natural and ecological framework should encompass all types of specially protected natural areas, ranging from nature reserves to pastures and hayfields, as well as certain types of disturbed lands. The justification for including disturbed lands within this framework lies in their potential for inclusion in the land fund [9].

A key aspect of environmental management within the territories encompassed by the natural and ecological framework is the careful handling of these areas. When combined with environmental measures, this can help to reduce the anthropogenic pressure on natural ecosystems, thereby promoting sustainable development.

To enhance the effectiveness of the measures implemented, it is essential to define a set of actions aimed at establishing a special protection regime.

The mode of protection should vary depending on the specific natural landscape. For forested areas, deforestation should be prohibited, except for sanitary felling.

For leveled areas within protected areas, plowing, the use of mineral fertilizers, and pesticides should be banned [10].

Hunting and fishing are permitted only for species that are not protected. Water bodies should be protected from pollution.

It is necessary to impose a ban on land allocation for construction, horticulture, and other uses, including the construction of buildings and infrastructure that are not required for the needs of nearby communities.

All economic activities that may harm or endanger the functioning and preservation of the natural ecosystem should be prohibited. As representatives of the plant and animal kingdom, we should be protected by law. The attitude towards the natural environment, its components, increases the power of irrational pressure. In this case, it is necessary to talk about anthropogenic factors of influence on nature. In this case, it is necessary to separate two types of influence on nature and its components, in particular on the climate, unintentional - in the process of economic activity and intentional - with the aim of changing, in this case, the climate, according to certain parameters for certain purposes [11].

Caring for our natural environment is essential for sustainable development. This is why the Federal Law "On Environmental Protection" has been enacted to regulate relations between society and nature [12]. Any form of economic activity poses a threat to our natural surroundings, which provide us with natural conditions and resources. In this regard, the Federal Law aims to address the challenges of preserving our natural environment, prevent and eliminate the harmful effects of human activity on nature, and improve the quality of our environment as much as possible.

Acknowledgments.

The work was carried out within the framework of the state assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 075-03-2021- 074 / 4).

Abstract

The impact of ecological tourism on the ecological conditions and ecosystem diversity within Adjara's protected areas has been thoroughly studied. The focus of these discussions encompasses the protected areas of Kobuleti, Kintrishi, Mtirala, and Machakhela, along with their existing infrastructure and the diverse services they offer.Moreover, a comprehensive analysis of plant diversity has been performed. This analysis indicates that the vegetation cover within these regions is marked by significant floristic diversity.It also highlights the presence of species with considerable conservation importance, particularly an abundance of endemic and relict species, as well as those listed on the Red List. The development of ecotourism has been observed to contribute to the preservation of natural beauty in unique areas, while simultaneously mitigating negative environmental impacts.Moreover, the threats posed by ecotourism to protected areas, including pollution, noise, fire, and the potential invasiveness of alien plant species, have been thoroughly examined. These threats significantly affect the protection and preservation of ecosystem diversity.A comprehensive analysis of the strengths and weaknesses associated with the development of ecotourism in the protected areas of Adjara, including its impact on the diversity of natural vegetation, has been provided. A statistical analysis of the visitor numbers to the protected areas of Adjara from 2018 to 2023 has been conducted.It has been observed that, despite Georgia's rich ecotourism resources, there is a current deficiency in marketable tourist products characterized by relevant properties. Moreover, it has been emphasized that ecotourism in protected areas not only cultivates new market segments and advances the tourism sector but also increases the efficiency of ecotourism and contributes to Georgia's economic development. An analysis of the development of ecological tourism in Adjara, identified as a crucial sector in the modern tourism industry, reveals that this area necessitates support at both the state and regional levels.This perspective is robustly corroborated by the 'Georgian Ecotourism Strategy 2020-2030,' collaboratively formulated by the Agency for Protected Areas of Georgia,the Austrian Development Agency (ADA), and the German Society for International Cooperation (GIZ). Within this strategy, it is acknowledged that ecotourism in Georgia notonly provides tourists with an authentic experience but also markedly boosts the economic well-being of the country. Furthermore, it plays a pivotal role in safeguarding naturaland cultural heritage and in elevating environmental awarenessamong both tourists and local inhabitants.

Keywords: ecotourism, protected areas, diversity, threats, statistical analysis

I. Introduction

Currently, the emphasis on developing ecotourism in protected areas worldwide is significant. Ecotourism in these areas respects ecosystem integrity and encourages nature-based travel. It serves as a pivotal economic driver for our region, fostering infrastructure growth, enhancing tourism-related businesses, thereby boosting local employment. Moreover, it plays a crucial role in preserving and promoting cultural heritage, traditional crafts and contributes to enhancing the country's international reputation.

Therefore, studying the challenges of ecotourism development in unprotected areas of Adjara is highly relevant, as it can generate substantial profits while maintaining ecological safety.

Given the growth of ecotourism in protected areas and its transformation into a significant socio-economic phenomenon, this research aims to address effective regulation issues in the organization of ecotourism. It also seeks to examine the impact of ecotourism on the ecological condition and biodiversity of Adjara's protected areas. The goal is to propose scientific and methodological recommendations that ensure ecological safety and preserve natural ecosystem diversity, as well as to coordinate the activities of economic entities at the regional level effectively.

To achieve this goal, the following tasks are set:

- Study the existing ecotourism infrastructure in the protected areas of Adjara;
- Investigate the diversity of ecosystems in the protected areas of Adjara;
- Examine the impact of ecotourism on the ecological condition of the protected areas of Adjara;
- Assess the impact of ecotourism on the biodiversity of the protected areas of Adjara.

The study focuses on four protected areas in the Adjara region: Kobuleti and Kintrishi protected areas, and Mtirala and Machakhela national parks.

II. Methods

The research methods used in this paper include:

- Route-expeditionary reconnaissance method
- Interview method: Engaging with visitor service specialists and rangers in the protected areas.
- Economic analysis and statistical methods (utilizing official statistical data for quantitative assessment)
- Analysis and synthesis methods
- Comparative analysis method: Comparing analytical and statistical data.

III. Results

The study examines the impact of ecotourism on the ecological condition and plant diversity of the protected areas in Kobuleti, Kintrishi, Mtirala and Machakhela. It also addresses the threats posed by ecotourism to these areas. Scientific and methodological recommendations have been developed, which, according to the authors, will aid in the formation and growth of the market for ecological tourism products, enhance ecological safety in protected areas, preserve vegetation diversity, and address the challenges hindering ecotourism development in the Adjara region.

In the process of implementing ecotourism activities in the unprotected areas of Adjara, the following observations were made:

- Ecotourism activities lead to both direct and indirect environmental changes, which can have positive and negative effects on wildlife.
- In the protected areas of Adjara, positive impact is reflected in responsible travel by visitors which promotes the protection and preservation of the natural environment.
- The adverse effects of ecotourism are most pronounced in the Kobuleti Nature Reserve and Mtirala National Park.
- Ecotourism negatively impacts the unique sphagnum habitat in Kobuleti Nature Reserve, causing artificial drainage and the introduction of invasive species. Rare species such as white moss (Sphagnum austinii) and globally red-listed species like the Colchian water-lilly (Nymphaea colchica) and water vine (Potamogeton natans) are at risk.
- Massive tourism in Mtirala National Park is endangering certain plant species listed on the

Red List of the Caucasus and Georgia.

- Visitor services in Kintrishi and Machakhela Protected Areas are managed with minimal negative impact on the environment, considering the capacity of natural ecosystems and national park zoning. Negative impacts include trampling of vegetation, pollution, noise, invasion of alien species, and, in rare cases, fires.

IV. Discussion

Ecotourism is emerging as a significant new sector in Georgia's tourism industry. Renowned for its natural beauty; diverse landscapes; Georgia offers attractions such as the Caucasus Range (with 668 glaciers); the subtropical Black Sea coastline (320 kilometers); rivers, lakes and waterfalls (25000 rivers and 860 lakes); mineral waters (1,400 mineral springs, most of them are thermal); cities carved into rocks, historical landmarks, traditional hospitality, and renowned Georgian cuisine, all contributing to its appeal as a tourist destination [1].

As of 2023, Georgia has designated 100 protected areas under six different categories based on IUCN criteria. These include 14 state reserves, 14 national parks, 40 natural monuments, 26 restricted areas, 5 protected landscapes, and one multi-use area. A total area of protected territory covers 912,862 hectares, which represents approximately 13% of Georgia's territory [2].

Today, Georgia faces the imperative of defining clear priority directions for regional development that ensure sustainable and stable regional growth. Concurrently, there is potential to cultivate new industries that can stimulate positive multiplier effects within the regions. One such priority direction identified is the development of ecotourism, seen as a pivotal component of Georgia's regional economic development strategy [3].

Considering that the Adjara region is one of the largest and most naturally diverse regions of Georgia, it is pertinent to examine the challenges and prospects of ecotourism development in Georgia today. Additionally, it is crucial to assess its impact on the ecosystem diversity and ecological condition of protected areas, using the Adjara region as a case study.

There are following protected areas in the A/R of Adjara [2]:

- Kintrishi Protected Areas (Kintrishi Nature Reserve 3 108 Ha; Kintrishi National Park with 20 406 Ha);
- Machakhela National Park, total area 7 333 Ha;
- Mtirala National Park, with total area 15 580 Ha;
- Kobuleti Protected Areas (Kobuleti Reserve with 316 Ha; Kobuleti Managed Reserve with 466 Ha).

The following table (Table 1) presents visitor statistics for the unprotected areas of Adjara from 2018 to 2023.

In recent years, (up to 2020 before the COVID-19 pandemic), Georgia experienced a consistent rise in both visitors and tourism revenue. The National Tourism Agency of Georgia identified 2019 as the peak year for the tourism industry’s growth. This trend was particularly evident in ecotourism, with a record (109,800) visitors reported in the protected areas of Adjara in 2019.

The COVID-19 pandemic has dramatically altered global lifestyles and triggered a crisis across all parts of life and sectors. In 2020, the tourism industry in Georgia, like worldwide, experienced a significant downturn. As shown in Table 1, the number of visitors to unprotected areas of Adjara dropped drastically by 81.8% compared to 2019, falling from 109.8 thousand to just 20.2 thousand.

Despite the disruptions caused by the pandemic, life and nature continue their cycles and everything has its begining and ending. From late 2021 into 2022, ecotourism began to rebound. By 2022, the number of visitors to unprotected areas of Adjara had risen to 85,700, marking an increase of 65,500 visitors (a 324.3% rise) compared to 2020. In 2023, ecotourism almost fully recovered, with visitor numbers reaching 104,300 in the protected areas of Adjara, which is 95.0% of the record high of 109,800 set in 2019 [2].

Table 1: *Number of visitor for the unprotected areas of Adjara 2018 – 2023*

Protected Areas		Number of visitor for the unprotected areas of Adjara 2018 – 2023, thousand persons					
		2018	2019	2020	2021	2022	2023
Total in Ajara A/R		88,8	109,8	20,2	56,3	85,7	104,3
Including	Kintrishi Reserve and National Park	6,6	7,0	1,2	1,8	2,9	3,1
	Machakhela National Park	10,1	11,3	0,8	0,5	0,9	1,4
	Mtirala National Park	57,8	77,3	15,4	51,1	78,1	95,3
	Kobuleti Reserve and Managed Reserve	14,3	14,2	2,8	2,9	3,8	4,5

Source: The table was created by the authors based on the reports from the Agency of Protected Areas of Georgia for the years 2018-2023

Today, as the COVID-19 pandemic subsides globally, many mass tourism destinations have implemented social distancing measures and established visitor thresholds based on the lessons learned during the pandemic. These practices may become a permanent aspect of tourism management, as ecotourism—particularly in protected areas—already required such restrictions to ensure sustainability and protect natural environments.

People are increasingly seeking destinations where they can feel safe and maintain social distancing, opting for less crowded places. Georgia's tourism sector faces the challenge of actively promoting ecotourism, which involves harmonizing tourism with natural resource conservation. Ecotourism can attract investment not only for environmental protection but also for the region's economic and socio-cultural development. Furthermore, advancing ecotourism provides local communities with the opportunity to generate additional income through tourism-related services.

Currently, Georgia possesses numerous ecotourism resources, but lacks a well-developed tourist product with defined market characteristics [4]. It is important to recognize that while ecotourism can create new market segments and expand the tourism sector, it also has the potential to significantly impact Georgian agriculture. By integrating ecotourism with agriculture, Georgia can enhance the efficiency of its ecotourism industry and contribute to overall economic growth.

A key factor for developing ecotourism in Adjara is its location within the Caucasus eco-region, known for its rich terrestrial biodiversity. The International Union for Conservation of Nature (IUCN) has listed this area as one of the world's biodiversity hotspots for its high levels of biological diversity and the presence of endangered terrestrial species. Adjara, with its varied ecosystems and unique geographical features, is recognized among the 200 global eco-regions for its species abundance, endemism, taxonomic uniqueness, and distinctive habitats in the southwestern corridor of the Lesser Caucasus [5].

Additionally, it is important to highlight that the World Wildlife Fund (WWF) initiative, "About 100 Hotspots of European Forests," which identifies approximately 100 critical protected forest areas in need of conservation, places a high priority on the unique Kolkheti forest ecosystems in Adjara [6].

Currently, Adjara's wild flora is estimated to consist of 1,837 species. According to literary sources, the endemic flora of Adjara includes 174 species, which belong to 43 families and 109 genera. This represents 9.47% of the total floristic composition of the region. These endemic species are distributed across the geographical regions of the Caucasus, Georgia, Kolkheti, Adjara-Lazeti, and Adjara [7].

The varied terrain and diverse climatic and soil conditions in the protected areas of Adjara contribute to a wide range of landscapes and ecosystems. In this relatively small region, one can find an array of ecosystems, from the lush mixed-leaved forests of the Kolkheti plain to the unique ecosystems of the high mountains with their more challenging climates. This results in a rich and intriguing vegetation profile [8].

In recent decades, Adjara's biodiversity has significantly declined due to various anthropogenic and natural factors, including habitat loss, fragmentation, degradation, illegal hunting and fishing, the introduction of alien species and unsustainable use of biological resources.

Protected areas in the Adjara region are crucial for tourism development. Kintrishi, Ispani, Machakhela Valley protected areas, Mtirala National Park, and the Botanical Garden have the most ecotourism potential. These areas offer exceptional and memorable experiences for ecotourism enthusiasts.

However, implementing ecotourism in these protected areas brings about changes in environmental conditions, influenced by both direct and indirect effects of tourism activities having positive and negative effect on wild nature as well. Studies have indicated that while ecotourism aims to offer nature-based tourism and recreation without harming natural ecosystems and promotes environmental protection, it inevitably impacts the environment. Research into protected areas has demonstrated that with effective management and well-defined planning, it is possible to mitigate negative environmental impacts and enhance the positive effects of ecotourism.

To evaluate the environmental damage caused by ecotourism in the protected areas of Adjara, interviews with visitor service specialists and rangers, along with observations on ecotourist routes, have revealed several issues. The pollution of both terrestrial areas and water bodies, such as rivers, ponds, and lakes, with food and household waste is a significant problem. Additionally, noise from entertainment facilities disrupts the ecological balance, frightening birds and other wildlife. There are also instances of visitors violating reserve regulations and causing damage to plants and animals. These issues represent only a portion of the negative impacts associated with ecotourism in these protected areas. It is crucial to recognize that preventing environmental damage is far easier than attempting to repair it once it has occurred.

Based on interviews with visitor service specialists and rangers in Adjara's protected areas, it is clear that those responsible for managing these areas are dedicated to organizing tourism activities while adhering to established rules and considerations. They have implemented measures such as creating ecological trails and installing informational boards. Additionally, they have developed designated walking and educational routes to enhance visitors' ecological awareness and improve recreational services.

Ecological trails have been established to manage tourist flow effectively in Adjara's protected areas. One significant issue is the trampling of these areas, which can damage important vegetation. Rangers focus on ensuring that tourists stay on designated routes to help preserve and protect these vital habitats. Currently, all four protected areas in Adjara have specialized routes for small groups, designed to avoid disrupting the integrity of natural environments while allowing for proper monitoring. These routes are carefully planned to prevent environmental damage. Additionally, the protected areas are equipped with facilities for travelers, including designated spots for resting, camping, lighting fires, and waste disposal. These amenities help minimize fire risks, maintain cleanliness in resting areas, and prevent uncontrolled trampling of the terrain.

The establishment of ecological paths in protected areas is crucial as it helps manage tourist traffic, reduces vegetation trampling, and thus aids in its preservation.

Informational stands with ecological content, including designated spots for resting and stopping, are strategically placed along tourist trails. These stands help minimize the creation of unauthorized parking areas and fire hazards, while also enhancing visitors' ecological education.

Ecotourism plays a vital role in protected areas by addressing various ecological challenges and contributing to their overall management and conservation.

Many plant species in the protected areas of Adjara are listed on international or Georgian red lists. The national park is notable for its rare diversity of endemic and relict plants. Among the rare relict endemics featured on Georgia's red list are the Pontic oak (*Quercus pontica*), Medvedevi birch

(*Betula medwedewii*), Ungern's rhododendron (*Rhododendron ungernii*), and Epigea (*Epigaea gaultherioides*). The latter two evergreen shrubs, along with Medvedevi birch, are found exclusively in Adjara and nearby regions of Turkey.

Although the tourist trails and ecotourism infrastructure in the protected areas of Adjara are generally well-maintained, there remain ongoing threats to the protection and preservation of biodiversity within these areas.

The main threats to the protection and preservation of biodiversity in the protected areas of Adjara, resulting from the development of ecotourism, are summarized in Table 2.

Table 2: *The main threats to the protection and preservation of biodiversity in the protected areas of Adjara*

Impact of ecotourism on the protected areas of Adjara						
	Threats to habitats and endemic relict species	**Reason**	**Impact level (assessment from 1 to 5)**	**Impact threat**	**Problem solution**	**Note**
1	Pollution	Household waste	3	Unaesthetic	Increase in awareness Fines	Negligence by visitors
2	Noise	Disruption of reserve's regimen by visitors	3	Disturbing birds		Rarely
3	Invasion of alien species	Habitat modification, degradation, drainage effect	4	Displacement of native species and dominance over their distribution	Ongoing monitoring and the development of proactive management strategies in alignment with the management plan.	Constantly

Source: The table was compiled using data from the 2023 report of the National Environmental Protection Agency and personal observations by the authors.

Contamination of protected areas, primarily due to visitor negligence, is largely attributed to solid waste pollution, which has been rated 3 out of 5 points in terms of impact. Addressing this issue could involve increasing visitor awareness and implementing fines. Noise pollution, resulting from visitors disregarding recommended guidelines and disturbing birds, is also rated 3 points for its environmental impact.

In the disturbed and degraded habitats within the protected areas and along adjacent paths, there have been instances of invasive plant species establishing themselves *(Spiraea japonica*, *Paspalum dilatatum*, and *Robinia pseudoacacia)*, particularly in Mtirala National Park and its vicinity. However, the Kolkhi forest remains relatively stable. This situation may represent an early stage of invasive species naturalization. Continuous monitoring and development of effective control measures are essential. The threat posed by invasive species to biodiversity is rated 4 points (see Table 3).

Additionally, the growth of ecological tourism in Georgia, particularly in the Adjara region, faces several challenges. These include inadequate legislation, as the legal status of ecological tourism remains unresolved (relevant laws and regulations are incomplete). There is also a need to define and clarify the concept of ecological tourism development. Furthermore, there is a lack of alignment between cooperation interests and the implementation of economic management mechanisms. Municipal bodies in the region are not fully leveraging their governance roles, which affects their ability to shape tourism policy and regulate tourism effectively [4].

Additionally, several factors hinder the development of tourism in Georgia, including:

- The seasonal nature of tourism, which results in significant periods of underutilization for a substantial portion of service personnel throughout the year;
- The risk of undermining the existing local cultural environment;
- Low awareness among the local population regarding the opportunities of ecological tourism;
- Underdeveloped road infrastructure;
- Lack of state support at both regional and local levels.

Regarding foreign investments, it is important to note that foreign investors have shown limited interest, largely because they do not view the Georgian market as a significant consumer base due to the relatively low income levels. Consequently, attracting foreign tourists to Georgia seems more promising. However, this also presents challenges: not only is there a lack of adequate infrastructure, but it is also crucial to create incentives to encourage their visit.

From our analysis of ecotourism within the contemporary tourism industry, it is clear that ecological tourism requires primary support at the regional level. Regional tourism business associations should take the lead in organizing the ecotourism sector. In our view, these associations need to address the following tasks to advance ecotourism in the Adjara region:

- Developing information systems to support regional ecotourism development programs and providing methodological guidance;
- Establishing effective mechanisms for creating new ecotourism attractions;
- Training skilled personnel to manage entrepreneurial activities within the tourism sector;
- Creating mechanisms for selecting and implementing promising investment projects aimed at advancing ecotourism.

Regional tourism business associations, alongside local administration, regional funds, labor exchanges, and other relevant organizations, should oversee the development of ecotourism infrastructure. This process should follow a state program designed to support ecotourism, which includes enhancing the legal and regulatory framework, improving methodological support and information networks, and building financial infrastructure through the involvement of funds, specialized banks, insurance companies, and investment institutions. Additionally, the program should engage technological, social and business sectors to ensure a comprehensive and effective development of ecotourism infrastructure.

Ecotourism has the potential to draw funds for enhancing the region's ecological security, as well as for its economic and socio-cultural development. Additionally, the growth of ecotourism helps increase public awareness of environmental issues and promotes ecological education.

VERTICAL COMPONENT LEVEL OF SEISMIC GROUND MOTION VELOCITY

Olga Erteleva

•

Schmidt Institute of Physics of the Earth, RAS, RUSSIA
ertel@ifz.ru

Abstract

Today it is considered proven that the vertical component of seismic ground motion makes a significant contribution to seismic loads on structures. For practical use in engineering calculations, it is necessary to assess the level of the vertical component. Taking into account growing interest to velocity of seismic oscillations, it is necessary to make such investigation and for vertical component of the seismic ground motion velocity. To solve this problem, the world empirical database of strong ground motions parameters of the earthquakes was used. Methods of statistical data processing were used. The first stage was the investigation of the ratio between the peak amplitudes of the maximal horizontal and vertical components of ground motion velocity, as well as the dependence of this ratio on the distance and magnitude of the seismic event It has been established that the dependence on magnitude is negligible. Taking into account the fact, that seismic oscillations in the near- and far- field zones of earthquakes have the different laws, further the dependence on distance was studied separately in each zone. As a result, correlation relationships for assessing the level of the vertical component of the velocity of expected seismic ground vibrations were developed, and the corresponding correlation coefficients and standard deviation values were computed. The obtained results can be used in calculating seismic treatments for the purposes of design and construction of seismic resistant structures.

Keywords: velocity, vertical component, amplitude, ratio, distance, seismic treatments

I. Introduction

One of the main tasks of providing comprehensive protection against earthquakes, which must be solved to reduce seismic risk, to decrease economic damage and human losses during earthquakes, is the seismic hazard assessment and the forecast of expected seismic treatments. In modern seismic resistant construction, seismic treatments are described by various quantitative parameters. The most commonly used one is acceleration; its characteristics have been studied in numerous works [1 – 7, etc.].

However, today in the practice of engineering calculations it is often necessary to take into account the velocity of seismic ground motions [8 – 11]. Nevertheless, this parameter has not yet been studied enough. In the scientific literature, one can mainly find only velocity attenuation equations [12 – 15, etc.]. Some authors propose the attenuation equations for vertical component of velocity [14, 16, 17, etc.]. The other characteristics are not practically researched. The vertical component of velocity also remains uninvestigated, although the need for such investigation is beyond doubt.

If special field observations are not carried out and the acceleration is used as the characteristics of seismic treatments, the level of the vertical component of acceleration is determined through the peak amplitude of the maximal horizontal component of ground motion. It was established that the relation between the accelerations on vertical and horizontal components significantly depend only on level of vibration [18].

Similar investigations for velocity of seismic ground motion have not been carried out.

The issue of the ratio of amplitudes on different components is very important, first of all, from a practical point of view. After all, if, as in the case of accelerations, there is a certain relationship between the levels of velocities on different components, then there is also the possibility of limiting research to studying only the maximal horizontal component of velocity of seismic ground motion.

II. Methods

To investigate the problem of assessing the level of vertical component of seismic ground motion velocity, the world empirical database of strong ground motions parameters of the earthquakes from different regions of the world with different tectonic settings was used. The interval of earthquake magnitude is $2 \le M_S \le 8$. The used distance was the shortest distance to the rupture surface. The interval of such distance is 0.01 km ≤ R ≤ 100 km. The soils were classified into 4 groups by seismic properties according to Russian building codes.

Used research method is statistical analysis of empirical data on strong ground motions.

The study contained several stages:

- firstly, the ratio between the vibration amplitude of the vertical component and the amplitude of the maximal horizontal component was considered;
- secondly, the influence of earthquake magnitude and distance on this ratio was considered;
- thirdly, mentioned above ratio was considered in both near- and far-field zone separately.

Finally, for each developed correlated relations the standard deviation and correlation coefficient were defined.

III. Results

So, let us consider the ratio of the oscillation amplitude of the vertical component PGV_{vert} and the maximal horizontal (or, what is the same, main) component PGV_{Hmax}. The ratio of the peak amplitudes of these components is presented in Figure 1.

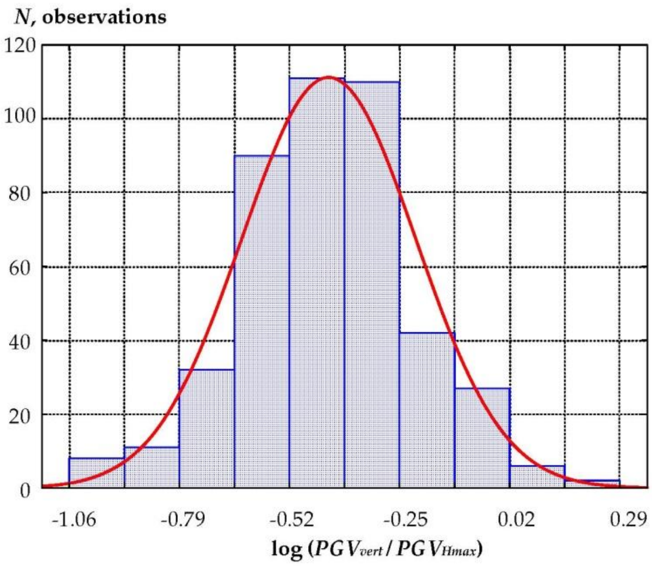

Figure 1: *Ratio of peak amplitudes of the vertical and maximal horizontal components (439 events). Red line is Gaussian distribution with parameters -0.43 ± 0.21.*

The average value of this ratio for a sample of 439 events is -0.43 units decimal logarithm, standard deviation σ = 0.21. The peak amplitude value of the vertical component is approximately 60% less than the peak value of the more intense horizontal component.

The dependence of the oscillation amplitude of the vertical component on the maximal horizontal one is graphically presented in Figure 2.

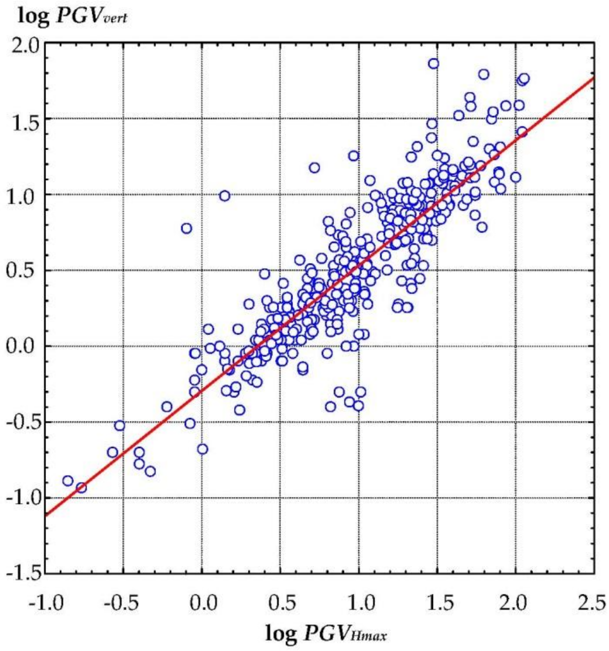

Figure 2: *Dependence of PGV_{vert} on PGV_{Hmax}.*
Circles are the empirical data (439 events); red line is approximating straight line

This relation is described by the equation:

$$\log PGV_{vert} = 0.82 \log PGV_{Hmax} - 0.29 \pm 0.29 \quad (1)$$

where PGV_{vert} - peak ground velocity (a maximal oscillation amplitude) of the vertical component, PGV_{Hmax} - peak ground velocity (a maximal oscillation amplitude) of maximal horizontal component (or, what is the same, main component).

The correlation coefficient in this case is $r = 0.87$.

With distance, the difference in levels between the vertical and maximal horizontal components increases, i.e. the vertical one grows faster, and with increasing magnitude, on the contrary, it decreases (Figure 3).

The corresponding formula for a sample of 159 events is:

$$\log (PGV_{vert} / PGV_{Hmax}) = 0.19 \log R - 0.06\, M_S - 0.38 \pm 0.33. \quad (2)$$

However, as can be seen from formula (2), the ratio of the levels of the vertical and maximal horizontal components to the magnitude is insignificant. The dependence on distance requires additional study.

Let us consider the dependence of the ratio of the amplitudes of the vertical and maximal horizontal components on distance separately for the near - and far – field zones. The relationship between far-field amplitudes ratio and distance is shown in Figure 4.

The equation of the approximating line has the form:

$$\log (PGV_{vert} / PGV_{Hmax}) = 0.08 \log R - 0.57 \pm 0.28. \quad (3)$$

As it is seen from equation (3,) the change in the value of log (PGV_{vert} / PGV_{Hmax}) over the entire considered range of distances does not exceed the standard deviation. So, the dependence on distance can also be neglected.

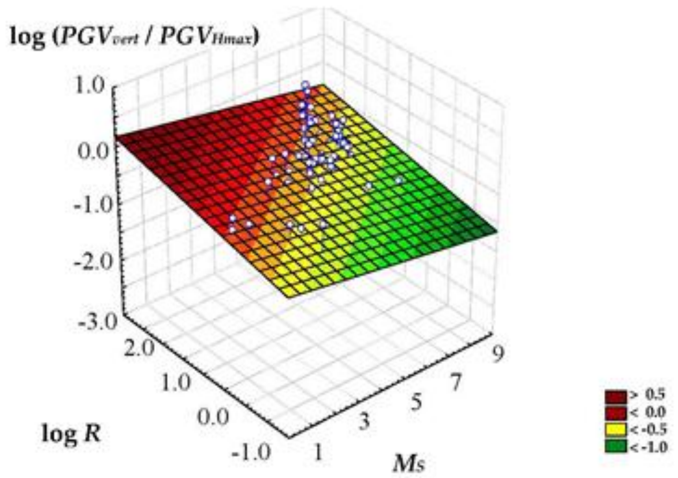

Figure 3: *Dependence of the ratio log (PGV_{vert} / PGV_{Hmax}) on the magnitude M_S and distance R. Circles are empirical data (159 events)*

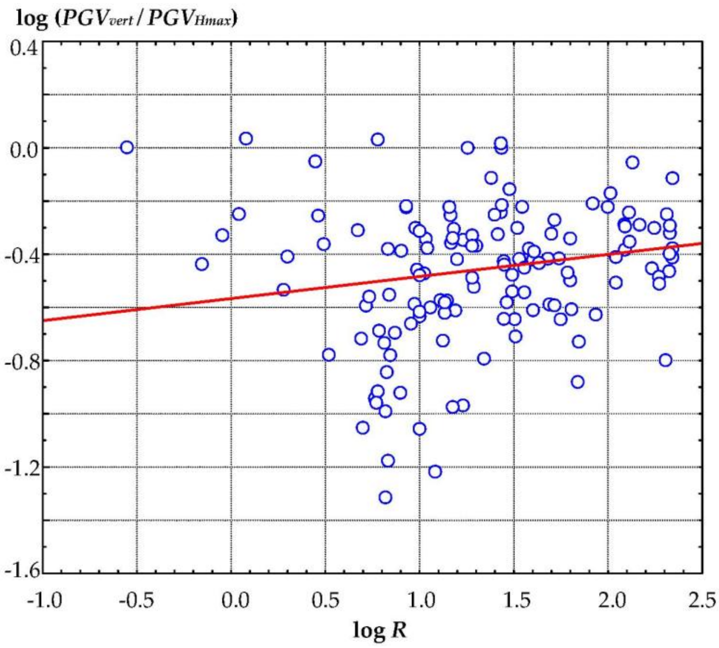

Figure 4: *Dependence of the value log (PGV_{vert} / PGV_{Hmax}) on the distance in the far-field zone. Circles are empirical data (144 events); red line is approximating straight line*

A similar picture is observed in the near - field zone.

Note, that magnitude and distance in equation (2) are correlated: small magnitudes are recorded only at short distances. As has been shown, the dependence of log (PGV_{vert} / PGV_{Hmax}) value on both distance and magnitude is insignificant. Therefore, equation (2) does not adequately describe the real dependencies. It is not for nothing that the distribution of the value log (PGV_{vert} / PGV_{Hmax}) without taking into account any factors (see Figure 1) has a lower standard deviation.

Let us consider the relationship between the levels of vertical and maximal horizontal components in the near - and far – field zones separately.

For the near -field zone (Figure 5)

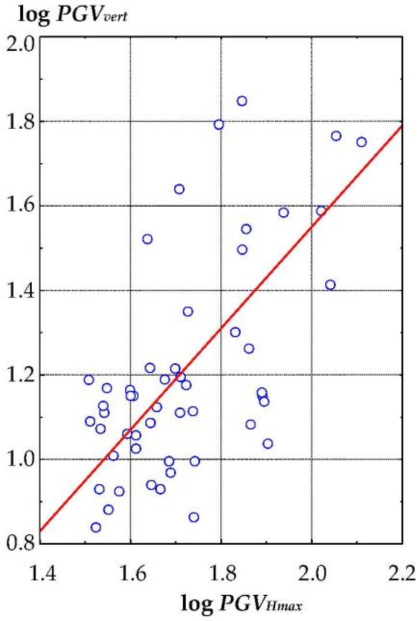

Figure 5: *Dependence of PGV_{vert} on PGV_{Hmax} in the near-field zone.*
Circles are empirical data (58 events); red line is approximating straight line

we have the next correlation relation:

$$\log PGV_{vert} = 1.20 \log PGV_{Hmax} - 0.85 \pm 0.14, \quad (4)$$

moreover, in the far-field zone (Figure 6)

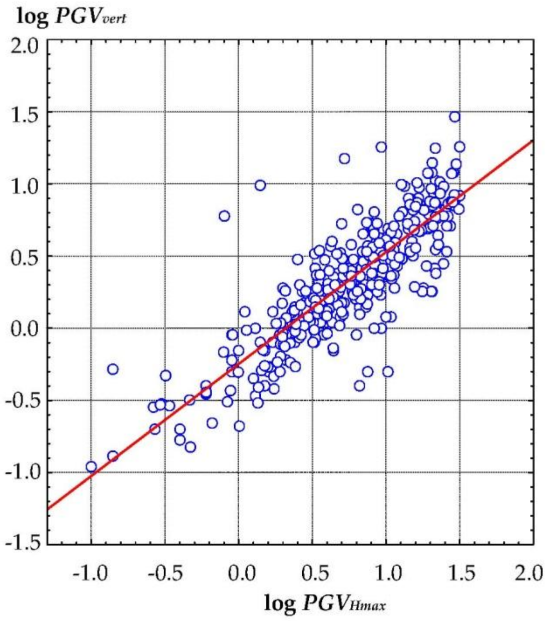

Figure 6: *Dependence of PGV_{vert} on PGV_{Hmax} in the far-field zone.*
Circles are empirical data (379 events); red line is approximating straight line

the relation was obtained

$$\log PGV_{vert} = 0.78 \log PGV_{Hmax} - 0.25 \pm 0.20. \quad (5)$$

The correlation coefficient of this relationship is high: $r = 0.87$.

IV. Discussion

Thus, as the empirical data analysis shows, the level of vertical component of seismic ground motion velocity is approximately in 1.7 times less than the peak value of the more intense horizontal component. It is the average estimation, without taking into account any factors as ground types at the observations point, the type of source mechanism, the distance and magnitude.

The influence of earthquake magnitude on the relation between the amplitudes of peak ground velocity of vertical component and the maximal horizontal component is insignificant. This relation is dimensionless value. In according the theory of dimension and similarity, the dimensionless quantity should not depend on the scale of the phenomenon.

As the result of research, the correlation relations for assessing the level of vertical velocity component were developed. These relations were obtained for near- and far-field zones of seismic wave field.

As in the case of accelerations, the relation between the velocities on vertical and horizontal components significantly depends on level of vibration. Therefore, the prediction of the amplitude level of the vertical velocity component of seismic ground motion is possible using data on the maximal horizontal component.

Abstract

Some results of statistical analysis of parameterized landslide (LS) data (the number of landslides and their areas) for 11 regions of Georgia (Autonomous Republic of Adjara, Guria, Imereti, Kakheti, Kvemo Kartli, Mtskheta-Mtianeti, Samegrelo-Zemo Svaneti, Racha-Lechkhumi and Kvemo Svaneti, Samtskhe-Javakheti, Shida Kartli, Tbilisi) from 1900 to 2022 are presented. Landslides count for Georgia is 1325, total area - 526.3 km^2. The area of individual landslides varies in the range from 0.0005 km^2 (Imereti, Samegrelo-Zemo Svaneti, Samtskhe-Javakheti) to 12.0 km^2 (Shida Kartli). In particular, the following results were obtained. Map of distribution of landslides number and their areas for different regions of Georgia is presented. Repeatability of the number of landslides and also their total area for different ranges of LS areas is study; the highest frequency of landslides in the study area falls on the range of their areas 0.0005-0.05 km^2 (41.5%), the smallest - on the range 5.01-12.0 km^2 (0.38%); the highest frequency of the total area of landslides falls on the range of their areas 1.01-2.0 km^2 (26.1%), the smallest – on the range 0.0005-0.05 km^2 (1.8%). The average annual shares of the total area of landslides from the area of study regions is calculated; this share in Guria (0.288%) and Adjara (0.281%) is significantly higher than in other regions - respectively, 5.05-4.9 times more than in Shida Kartli and 28.8-28.1 times more than in Samegrelo-Zemo Svaneti. The relative coefficient of the total area of landslides (RC) for individual region is calculated. RC = (Landslides average area in region/Sum average landslides area in all regions)/(Region area/All regions area); the RC value for Guria and Adjara, respectively, is 6.26 and 6.13 and 3.6-3.5 times more than in Shida Kartli and 27.2-26.7 times more than in Kvemo Kartli and Samegrelo-Zemo Svaneti. The relative landslide risk ratio for the population of study regions (RLR) was calculated. RLR = RC·(Region population/All regions population). The highest RLR value is observed for Adjara (0.60); for Guria and Tbilisi - 0.17 each (approximately 3.5 times less). The lowest RLR values are observed for Racha-Lechkhumi and Kvemo Svaneti (0.007).

Keywords: natural disaster, dangerous geological processes, landslides, landslides area.

I. Introduction

Landslides are a type of natural disaster. Landslide processes are widespread almost everywhere, including in Georgia, and are dangerous due to damage to residential buildings, roads, infrastructure, etc., often accompanied by human casualties [1-4]. In particular, according to incomplete data [5,6], in Georgia in 1996-2020 the total number of reactivated and new cases of landslides was about 12000. Therefore, the study of landslide processes in this country has always been and is given special attention [7–9].

An analysis of extensive material on landslides in Georgia showed that there is not so much systematic data about this natural phenomenon. In connection with the above, we collected the most reliable values of the main parameters of landslides, determined on the basis of the totality of available information. These included the date of occurrence (year, month, day), time of occurrence (hour), location of occurrence (geographical coordinates), magnitude and intensity [7,10], where appropriate, affected area and associated losses (number of fatalities; casualties in economic terms). As a result of this work, the first systematic catalog in Georgia was created for this natural phenomenon, as one of the five natural disasters (landslides, debris flows, flash floods, windstorms and hailstorms) [11,12].

The Landslide Catalog contains 1636 events for the period from 1900 to 2022, including, in particular, data on their areas.

At this stage of research, the results of a statistical analysis of data on the number of landslides and their areas for 11 regions of Georgia in the period from 1990 to 2022 are presented.

II. Study area, material and methods

Study area is Georgia and their 11 regions (Autonomous Republic of Adjara, Guria, Imereti, Kakheti, Kvemo Kartli, Mtskheta-Mtianeti, Samegrelo-Zemo Svaneti, Racha-Lechkhumi and Kvemo Svaneti, Samtskhe-Javakheti, Shida Kartli and Tbilisi).

Table 1: *Study area, population, period of observations and height range on landslides emergence in Georgia.*

Region	Region, Abbr	Regional center	Area, km²	Population (thous.)	Period of observations	Number of years	LS height range (m,a.s.l.)
Autonomous Republic of Adjara	Adj	Batumi	2919	363	1968-2022	21	2-1846
Guria	Gur	Ozurgeti	2033	102	1979-2022	13	28-553
Imereti	Im	Kutaisi	6516	442	1940-2022	26	21-965
Kakheti	Kakh	Telavi	11310	300	1974-2022	10	440-1974
Kvemo Kartli	KK	Rustavi	6528	436	1977-2022	8	285-1361
Mtskheta-Mtianeti	M-M	Mtskheta	6785	93	1963-2022	28	497-3773
Samegrelo-Zemo Svaneti	S-ZS	Zugdidi	7441	288	1900-2017	28	33-2384
Racha-Lechkhumi and Kvemo Svaneti	R-L KS	Ambrolauri	4690	26	1966-2022	35	354-1838
Samtskhe-Javakheti	S-J	Akhaltsikhe	6413	142	1973-2022	14	797-2468
Shida Kartli	Sh K	Gori	3429	244	1971-2022	14	509-1000
Tbilisi	Tb	Tbilisi	504	1259	1973-2022	25	437-1376
Georgia	Geo	Tbilisi	58567	3695	1990-2022	60	2-3773

In Table 1 information on the above mentioned study area, population [https://en.wikipedia.org/wiki/Administrative_divisions_of_Georgia_(country)], period of observations and height range on landslides emergence in Georgia are presented. In particular, the area of the studied regions vary from 504 km² (Tbilisi) to 11310 km² (Kakheti); population vary from 26 thousand (Racha-Lechkhumi and Kvemo Svaneti) to 1259 thousand (Tbilisi) [https://www.geostat.ge/en]; period of observations - from 1990 to 2022; number of years of observations - from 8 (Kvemo Kartli) to 35 (Racha-Lechkhumi and Kvemo Svaneti). In general, in Georgia, the study area is 58567 km^2, population – 3695 thousand and the number of years of observations is 60. The height of landslides emergence in Georgia vary from 2 to 3773 meters.

The work used catalog data [12] on the landslides and their areas for 11 regions of Georgia in the period from 1990 to 2022 (1375 cases in total).

In the proposed work the analysis of data is carried out with the use of the standard statistical analysis methods.

The following designations will be used below: Mean – average values; Max - maximal values; Min – minimal values; St Dev - standard deviation; St Err - standard error; Low and Upp – lower and upper levels of the confidence interval of the mean within standard error; LS – landslide. RC - relative coefficient of the total area of landslides in region; RC = (Landslides average area in region/Sum average landslides area in all regions)/(Region area/All regions area). RLR - relative landslide risk ratio for the population of study regions; RLR = RC·(Region population/All regions population).

III. Results

The results in Fig. 1-6 and Table 2 are represented.

In Fig. 1 map of distribution of landslides number and their areas for different regions of Georgia is presented. In Table 2 statistical characteristics of Fig. 1 data is represented.

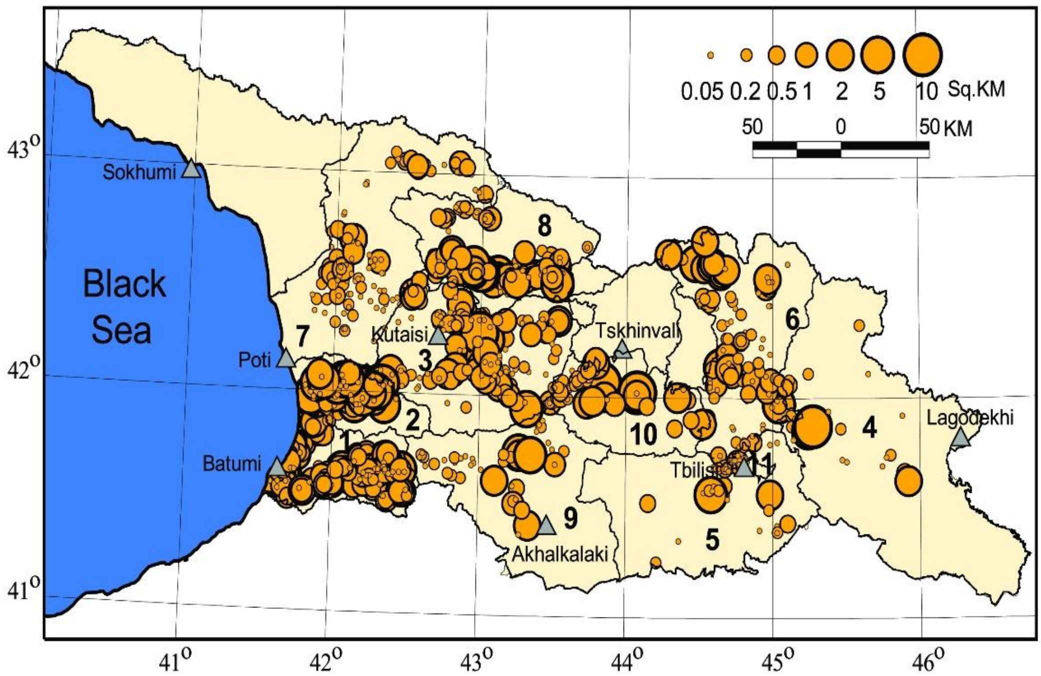

Figure 1: *Distribution of landslides area in Georgia*
1 – Autonomous Republic of Adjara, 2 – Guria, 3 – Imereti, 4 - Kakheti, 5 - Kvemo Kartli, 6 - Mtskheta-Mtianeti, 7 - Samegrelo-Zemo Svaneti, 8 - Racha-Lechkhumi and Kvemo Svaneti, 9 - Samtskhe-Javakheti, 10 - Shida Kartli, 11 - Tbilisi.

As follows from Fig. 1 and table 2, the distribution of the number of landslides and their areas on the territory of Georgia is extremely uneven. In particular, LS count vary from 23 (Kvemo Kartli) to 300 (Autonomous Republic of Adjara). LS count for Georgia is 1325. The area of individual landslides varies in the range from 0.0005 km^2 (Imereti, Samegrelo-Zemo Svaneti, Samtskhe-Javakheti) to 12.0 km^2 (Shida Kartli).

Table 2. *Statistical characteristics of landslide areas in different regions of Georgia (km²).*

Region	Adj	Gur	Im	Kakh	KK	M-M
Min	0.001	0.0007	0.0005	0.00132	0.0017	0.001
Max	2.7	3.7	8.4	6.0	2.2	4.1

Total area	21.5	74.1	15.5	38.7	2.8	526.3
LS count	138	260	49	78	53	1325

The total landslides area changes from 2.8 km² (Tbilisi) to 172.5 km² (Autonomous Republic of Adjara). For Georgia the total landslides area is 526.3 km². On average, the area of landslides vary from 0.05 km² (Tbilisi) to 0.97 km² (Guria). In Georgia as a whole, this area is 0.40 km².

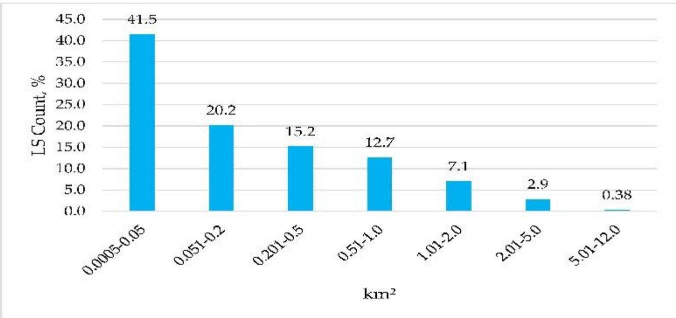

Figure 2: *Repeatability of the number of landslides at different ranges of their areas.*

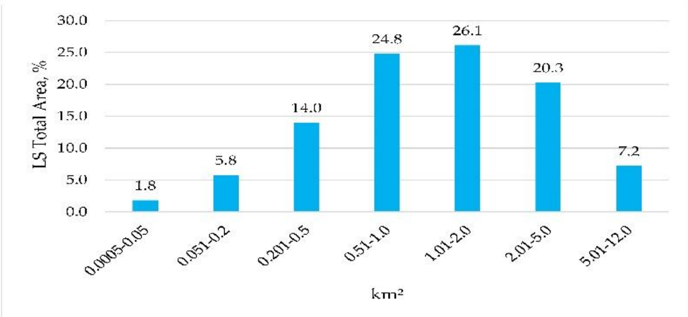

Figure 3: *Repeatability of the total area of landslides for different ranges of their areas.*

From Fig. 2 it follows that the highest frequency of landslides in the study area falls on the range of their areas 0.0005-0.05 km² (41.5%), the smallest - on the range 5.01-12.0 km² (0.38%). At the same time, as shown in Fig. 3, the highest frequency of the total area of landslides falls on the range of their areas 1.01-2.0 km² (26.1%), the smallest – on the range 0.0005-0.05 km² (1.8%).

	Gur	Adj	Sh K	R-L KS	Im	M-M	S-J	Tb	Kakh	KK	S-ZS
Low	0.001	0.156	0.030	0.035	0.009	0.014	0.008	0.010	0.005	0.005	0.007
Mean	0.288	0.281	0.057	0.045	0.039	0.022	0.017	0.016	0.011	0.011	0.010
Upp	0.578	0.406	0.084	0.056	0.068	0.029	0.026	0.022	0.017	0.017	0.014

Figure 4: *Mean annual share of the total area of landslides from the area of the region.*

Taking into account that the studied regions have different areas, we calculated the average annual shares of the total area of landslides from the area of these regions (Fig. 4). As follows from Fig. 4, this share in Guria (0.288%) and Adjara (0.281%) is significantly higher than in other regions: respectively, 5.05-4.9 times more than in Shida Kartli and 28.8-28.1 times more than in Samegrelo-Zemo Svaneti.

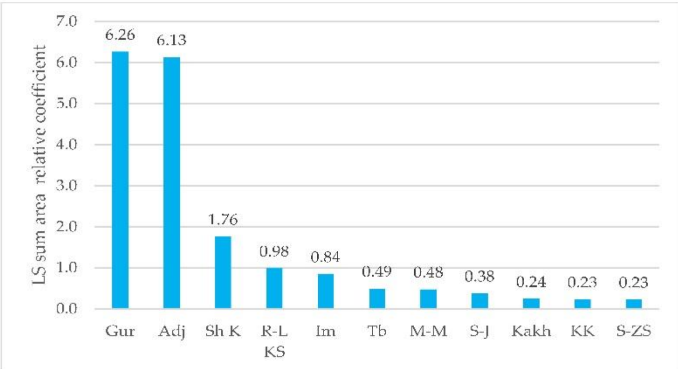

Figure 5: *Relative coefficient of the total area of landslides for different regions of Georgia.*

Taking into account that the amount of systematic data on landslides in Georgia is much lower than the total recorded amount (for example, about 5% in 1996-2020 [5,6,12]), we calculated the relative coefficient of the total area of landslides RC for individual regions (Fig. 5). As follows from this figure, the RC value for Guria and Adjara, respectively, is 6.26 and 6.13 and 3.6-3.5 times more than in Shida Kartli and 27.2-26.7 times more than in Kvemo Kartli and Samegrelo-Zemo Svaneti.

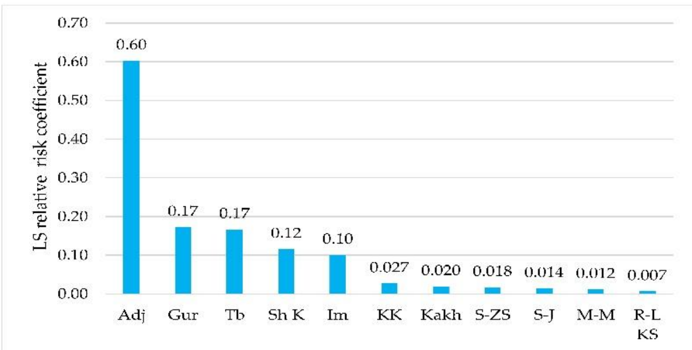

Figure 6: *Relative landslide risk ratio for populations of different regions of Georgia.*

Finally, taking into account the number of inhabitants in the study regions of Georgia, the relative landslide risk ratio (RLR) for the population of these regions was calculated (Fig. 6). As follows from Fig. 6, the highest RLR value is observed for Adjara (0.60); for Guria and Tbilisi - 0.17 each (approximately 3.5 times less). The lowest RLR values are observed for Racha-Lechkhumi and Kvemo Svaneti (0.007).

IV. Discussion

Landslide (LS) processes are widespread almost everywhere and are dangerous due to damage to residential buildings, roads, infrastructure, etc., often accompanied by human casualties. This problem is also very relevant for Georgia. According to incomplete data the total number of landslide on the territories of Georgia in 1996-2020 was near 12000 [5,6]. Therefore, the study of landslide processes in Georgia has always been and is given special attention.

An analysis of extensive material on landslides in Georgia showed that there is not so much parameterized data about this natural phenomenon. In connection with the above, by us made the first systematic catalog in Georgia was created for this natural phenomenon, as one of the five natural disasters (landslides, debris flows, flash floods, windstorms and hailstorms) [11,12].

The Landslide Catalog contains 1636 events for the period from 1900 to 2022, including, in particular, data on their areas. At this stage of research, a statistical analysis of data on the number of landslides and their areas for 11 regions of Georgia in the period from 1990 to 2022 carried out (1325 LS events).

In particular, it has been quantitatively confirmed that in terms of relative landslide-hazardous area, the most vulnerable regions are Guria and Adjara, significantly exceeding all other regions. In terms of the level of landslide risk for the population of these regions, Adjara is the most unfavorable, followed by Guria and Tbilisi.

V. Conclusion

In the near future, we plan to conduct a statistical analysis of such LS catalog parameters as magnitude, intensity, economic loss. In addition, it became possible to significantly improve the quality of mapping the territory of Georgia using parameterized data on landslides, to clarify the quantitative relationships of landslides with various geological, geophysical and atmospheric processes (in particular, with precipitation [13]). We also plan to continually update the catalog data as new information becomes available [14,15].

THE INCREASE IN THE INTENSITY OF DESERTIFICATION DUE TO CLIMATE CHANGE IN THE TERRITORY OF THE NORTH CHECHEN LOWLAND

Idris Bayrakov
•
A.A. Kadyrov Chechen State University, RUSSIA
idris-54@mail.ru

Abstract

Desertification processes that have covered significant areas in the North Chechen Lowland, caused by anthropogenic impact exceeding their stability, have intensified due to climate change. The temperature regime has changed significantly over the past 30 years, the temperature has increased by 1-1.5 degrees, and the amount of precipitation has decreased – less than 250 mm per year, evaporation has increased and in summer can reach up to 2500 mm or more. Under these conditions, degradation processes leading to the reduction of vegetation cover and to the destruction of soil cover, causing the activation of deflationary processes. Dust storms have become quite frequent. The areas exposed to desertification processes exceed more than 270,000 hectares, including more than 100,000 hectares of open sand masses overweighed by wind.

Keywords: desertification processes, climate change, deflation processes, arid landscapes, North Chechen Lowland

I. Introduction

Arid landscapes occupy the northern regions of the Chechen Republic. Within this type of landscapes, 1 subtype is distinguished — semi—desert and desert, which is divided into 1 genus - lowland-lowland accumulative with wormwood (with fragrant wormwood, Tauric and Lerkha), solyanka deserts and wormwood-cereal semi-deserts and 3 types of landscapes (Fig. 1.).

The relief is dominated by low-lying plains with absolute heights from 5 to 200 m, composed of Pleistocene marine rocks and loess-like loams. The climatic conditions are characterized by continentality and aridity. The temperature of the coldest month (January) ranges from -4.4 to 1.8° depending on the location. The hottest month is July, with a temperature of 23.5-25.2°. Accordingly, the annual temperature reaches 9.7-11.1 °. The sum of active temperatures reaches 3550-3600 °. The low amount of precipitation (300-350 mm) determined the "fragility" of the connections between the components of nature and the "vulnerability" of semi-desert landscapes. The soils here are sandy, chestnut and light chestnut with an abundance of salt marshes and salt marshes. They are not very fertile, so for a long time the main resource used in human economic activity was the wormwood-grass steppes adjacent to the floodplain of the Terek River. When moving to the northeast, with the increase in aridity of the climate, vegetation is thinned, sod cereals gradually disappear and pickles acquire an increasingly important role in the cover. At the same time, the influence of microrelief is increasingly beginning to affect the composition of vegetation cover. Even with minor changes in the surface, there is a sharp change in plant groupings: from grass-steppe associations of wormwood and solyanka.

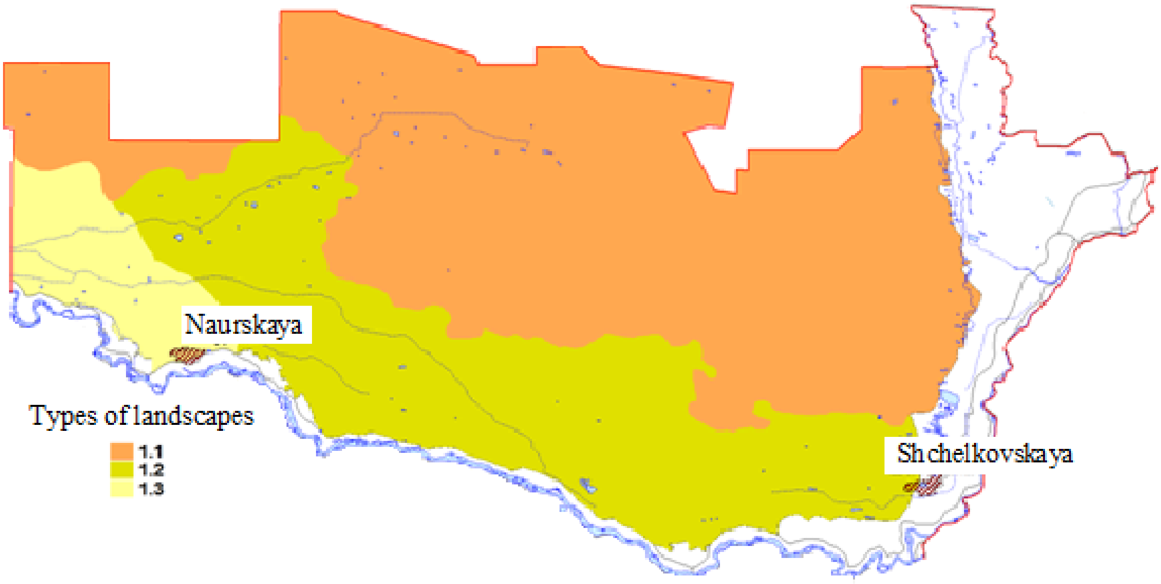

Figure 1: *Types of arid landscapes of the North Chechen lowland*
The legend of the map

1.1. A low-lying slightly inclined alluvial plain, composed of developed and intertwined sands, with a wide range of Aeolian relief forms, with semi—desert (Taurian wormwood, Marshall, Austrian) and sand-loving (erianthus Rowenna, impereta cylindrical, kendyr Sarmatian) vegetation on light chestnut soils - occupies the territory of the Tersk sandy massif, where typical Aeolian landforms with the most arid climate;

1.2. A low-lying, slightly inclined alluvial plain, composed of developed and intertwined sands with fragments of Aeolian relief, with grassy and grassy desert steppes and sand lovers on light chestnut soils, adjoins the Tersk sandy massif from the south, but the Aeolian landforms are not so widely represented here and mainly in the northern part, the climates are only slightly less drier than in the Tersk sand massif;

1.3. A low-lying slightly inclined alluvial plain composed of sands with fragments of Aeolian relief, with grassy semi-steppe and steppes (grassy-grassy, grassy—wormwood and borodachev) on dark chestnut soils is the least arid and somewhat more elevated part adjacent to the Tersk sandy massif from the southwest, Aeolian relief is extremely rare, The composition of the flora is influenced by the proximity of the real steppes.

The information currently available on the nature and distribution of the vegetation cover of the Zaverechye has accumulated as a result of research by a number of botanists. Of these, P.V. Novopokrovsky (1922, 1925, 1926), S.A. Vinogradov, G.A. Tolchin (1932), S.E. Rozhenits-Kucherovskaya (1925), A.D. Gozhev (1930), S.M. Borisov (1946) should be noted. Since the end of the 19th century, pastures of arid landscapes have been actively used year-round, which naturally led to their degradation and the manifestation of deflationary and Aeolian processes here. The anthropogenic factor intensified by climate change actively interfered with the natural course of evolution of these landscapes, which led to a significant transformation of natural components and the geosystem as a whole.

II. Methods

The North Chechen lowland has significant diversity of vegetation cover both in its genesis and species composition. Here we find plant associations of past eras, as well as modern formations and adjacent territories. In order to better understand the origin of the existing forms of plant associations, the history of their formation has been traced since the beginning of anthropogenic.

The territory of the North Chechen lowland in the modern era, three transgressions of the Caspian Sea have been traced: Baku, Khazar, Khvalyn, which alternated with periods of sea retreat - regressions. The territory of the North Chechen Lowland released after the Khvalyn transgression is exposed to climatic and anthropogenic factors. The main methods of our research of vegetation cover are the field route, which allowed us to establish the evolution and its patterns. Botanical methods are based on direct observation of the external appearance of forms and elements of plant associations, identification of their features and typical features, as well as the study of their spatial relationships.

In visual ground surveys, the main work is carried out at the reference points. They are chosen so that they can characterize one of the forms of plant associations, or a system of genetically related groupings. At the reference points of the study, a detailed botanical and geographical assessment of the studied plant associations is given: their appearance and spatial placement are described. The main method was field research by routes that ran from south to north, the reference points were located at the corners of squares with sides of 5 km. Dozens of photographs were taken. The basis has been laid for further studies of vegetation cover. The complex nature of our research has allowed us to determine that the main factor that provoked deflationary processes here is the anthropogenic factor. Since the second half of the last century, the process of intensive warming began, which naturally intensified deflationary processes.Our research covers a significant part of sandy landscapes that are subject to intense deflationary processes.

III. Results

A new type of landscape has been formed, where the anthropogenic factor of evolution plays a significant role. The Naursko-Shelkovskaya natural and anthropogenic landscape occupies the western part of the Priterskiy sand massif on the territory of the Naursky and Shelkosky districts. The natural functions of the landscape have been preserved over a significant area, they are weakened by forms of farming (watering and irrigation) and overgrazing of livestock. The coefficient of anthropogenic disturbance is 0.9.

The component subsystem is represented by a set of all natural components that have been modified by humans to varying degrees. The soil and plant components were particularly affected. Most of the landscape consists of upper quaternary alluvial-marine deposits (sands, sandy loams). Modern alluvial deposits (pebbles, sands, sandy loams) are common in the Terek Valley.

The terrain is dominated by alluvial-marine Late Pleistocene flat lowlands with fluctuations in relative heights of no more than 80 m. The maximum heights in the north-west of the landscape are up to 100 m. The alluvial-marine Holocene lowlands are widespread in the northeast. In the south, the landscape is bounded by the flood plain of the Terek River. The central position is occupied by the alluvial plain of Ak-Terek. The climate is harsh, the average temperatures in July are up to +25, in January – 4.0, -5.0 OC. A small amount of precipitation falls per year (250-300 mm) with an evaporation rate of 900-1000 mm. During the period of full vegetation of plants (from April to October), the amount of precipitation is even less — 120-150 mm. The transition through 0 C and the beginning of the frost-free period in the landscape takes place on average on March 6-10. The average daily temperatures exceed the threshold of +5.0 oC on March 27-30 and only by April 17-20 begins the period of full vegetation, lasting 185-190 days. During this time, the potential of active temperatures of 3540.0-3550.0 °C accumulates on the territory of the landscape. GTC = 0.4-0.5; the moisture coefficient rarely exceeds 0.3 per year. The summer months are the driest of the year (Cvl< 0.2), the number of days with relative humidity below 30% at 13 o'clock is about 11-18 (in some years more).

The river network is represented by the Terek transit River, which has no tributaries. Surface runoff is increased by a system of canals and irrigation systems. The Tersko-Kuma Canal, its Naursko-Shelkovskaya branch, begins its course here. The Burun Branch departs from these channels to the northeast. Groundwater aquifers are confined to the Akchagyl and Absheron rock layers. The zonal type of vegetation is cavill-grass communities in combination with soleros.

This is a typical vegetation of semi-deserts. In the east of the landscape, a significant area is occupied by vegetation of bumpy sands. In the lower reaches of the Terek, meadow-marsh and salt marsh vegetation of the floodplains and floodplains was widespread. The soil cover is dominated by light chestnut soils of sandy loam and light loamy mechanical composition. In the northern and northeastern regions of the landscape, salt marshes and salt marshes occupy from 10 to 40% of the area. Significant areas fall on the alluvial soils of the Terek River Valley.

The composition of material culture has been enriched with man-made components: roads, power lines and communications, canals, drilling rigs and oil storage facilities, artesian wells, farm buildings and rural settlements. The ploughing of the territory is large and exceeds 45%. The main arable lands are adjacent to irrigation systems.

The morphological subsystem has good pasture and soil resources. Areas with natural FABRICS prevail The biocenotic subsystem is represented by natural TCS, which occupy more than 60% of the area and are used as pastures: 1) oligodominant bioecosystems of cereal-wormwood communities; 2) oligodominant bioecosystems of wormwood communities, soleros. Geotopes with a quasi-natural environment include: 1) monocultural bioecosystems of irrigated lands (vineyards, fodder, melons, etc.); 2) monocultural bioecosystems of rainfed lands with a predominance of winter wheat; 3) rare forest belts in the northern regions of the landscape (Fig.2).

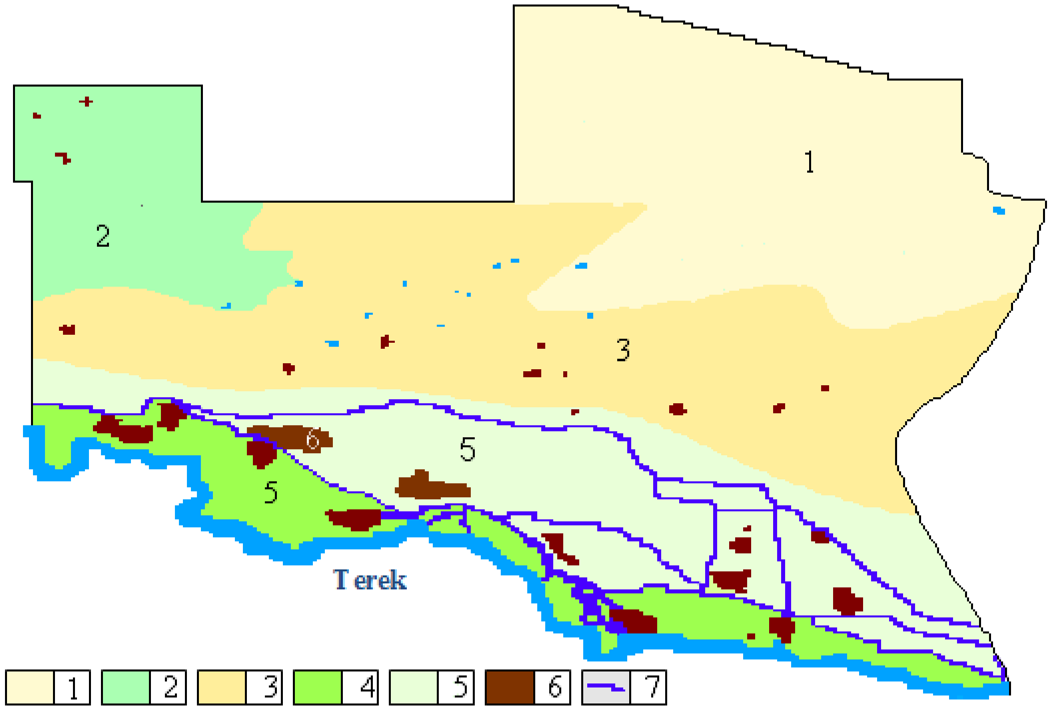

Figure 2: *Morphological structure of the Naursko-Alpatov natural and anthropogenic landscape of 1-5 localities (description in the text) Symbols:*

1).marine accumulative lowlands, composed of Khvalyn deposits (sands, clays), with sagebrush deserts and agrophytocenoses on light chestnut soils;

2) Aeolian deflationary-accumulative lowlands, composed of Aeolian deposits, which are overgrown with cereals; 3) alluvial-marine accumulative plains, composed of Khvalyn continental and marine deposits, with wormwoodgrassy desolate steppes on light chestnut soils;

4) floodplain modern alluvial plains with salt marshes and marsh-salt meadows and floodplains on alluvial saline meadow-marsh soils;

5) river terraces on alluvial deposits with chestnut and patches of dark chestnut soils;

6) residential complexes (Naur, Alpatovo, Ishgorskaya, etc.) mainly with cottage buildings, gardens and vegetable gardens, pasture pastures and irrigation canals. The population density is 10-18 people per km2;

7) irrigation canals

The functioning of modern landscapes still retains a natural character, but anthropogenic processes have made significant changes to their structure, especially component ones (water cycle, geochemical processes, growth of anthropophytes in vegetation, etc.). Dynamics occurs according to a semi-desert type in a continental climate (hot dry summers and moderately cold low-snow winters). The optimal ratio of heat and moisture is observed only from mid-April to mid-June. The evolution of landscapes is associated with their transition to the stage of natural-cultural (northern) and cultural-natural (southern parts). With the introduction of large masses of water into natural circulation by the Tersko-Kuma Canal, large areas of semi-deserts were plowed. Low soil fertility has determined the involvement of a large number of chemical elements, including toxic ones, in natural cycles. Currently, the semi-desert landscapes have begun to show the processes of their degradation (soil salinization, waterlogging, wind erosion, desertification, etc.). The territory of the North Chechen lowland belongs to the zone of insufficient moisture (aridity of the climate, lack of moisture, salinity of soils, soils of light mechanical composition), fragility and instability of natural ecosystems. Irrational and uncontrolled use of natural forage lands of the North Chechen lowland, high loads on natural pastures, often 2-5 times higher than their soil infertility, progressive desertification of the territory of the North Chechen Lowland. Thus, 50-70 years ago, an unsatisfactory economic condition was noted only on 8% of the area of natural pastures, and currently more than 80% of the area of pastures in the North Chechen lowland has been knocked down, degraded and subject to deflationary processes.

IV. Discussion

The methods of accelerated ecological restoration are based on the basic scientific principles of biogeocenology, physical geography, ecology and geoecology.

These are the principle of floristic and coenoptical completeness of communities, the concept of the types of adaptive strategies of plants, the principle of ecological differentiation of ecological niches and the interaction of species, and the principle of conformity of the design of restored pasture ecosystems with zonal types of biogeocenotic structures (Shamsutdinov, 1998). Lalymenko and Albukaev made a huge contribution to the study of the geoecological state of the arid territories of the Chechen Republic, 1997.

The region belongs to the southern tip of the agricultural belt of Russia with its arid, semiarid and dry semigumid zones - lands of varying degrees of vulnerability affected by desertification. Therefore, the development of a scientific basis for the organization of systematic actions to combat desertification of agricultural lands, using the example of this region, is extremely important to ensure the sustainable development of the entire North-Eastern Caucasus, and will be a guideline for carrying out similar work in other regions prone to desertification (Petrov, 1950,1973).

Sand dunes are found in relatively small areas in the northern and eastern parts (Lalymenko, Albukaev, 1978., Bayrakov, 1996, 1978, 2009).

V. Conclusion

One of the most important environmental problems of our time is anthropogenic desertification, which has covered significant areas of land on our planet. The predominant territory of the arid zone of the North-Eastern Caucasus is used extensively, mainly as natural pastures with unstable and unproductive vegetation cover. An attempt to intensify the economic use of natural pastures without carrying out the necessary agroforestry measures in a semi-desert zone leads to degradation and desertification of landscapes (Bayrakov, 1997, 2004).

According to its physical and geographical features and from the point of view of the direction of economic use, the Priterskiy sand massif is a sharply defined area. The uniqueness of its landscapes in comparison with the surrounding spaces is determined, first of all, by the hydrological conditions of the sands. Typical meadow phytocenoses are found in depressions with close groundwater occurrence. The properties of sands to accumulate and retain moisture throughout the growing season, to some extent neutralize and mitigate the effect of arid climate, create conditions approaching those of a more northern steppe zone.

When using semi-desert ecosystems as forage lands for year-round grazing, it is necessary to take into account the type of grazing cattle and the climatic conditions in which the ecosystem of pasture lands functions. The rate of the desertification process depends on their ecological state and degree of destruction, the threshold values are 0, 25, 50, 75 and 100% of the ecosystem area. If we trace the history of the development of the vegetation cover of the plain, then we can restore the course of restoration to its original state according to the following scheme:

• at the first stage, arable land is overgrown with associations of wormwood, which includes other species: porcine, roofing and spreading bonfire, larkspur, bunny, small-flowered milkweed and field bindweed. This group of plants in this composition develops within 5-10 years;

• at the second stage, the dominance gradually shifts to a plant association with roofing and spread-out bonfires, which includes wormwood, milkweed Seguer, tipchak, like sandy, larkspur, borage, carrot, whiteflower dubrovnik, blue alfalfa and a number of other plants;

• at the third stage, we notice an increase in the sod of piggery, when its rhizomes are closed, conditions of constraint are created and often the displacement of previously dominant plant species and piggery almost completely takes over. In addition to the above-mentioned plant species, this new association includes euphorbia, thyme, roofing and spreading bonfire, broom wormwood, hair-like feather grass, whitewater dubrovnik, bunny, larkspur, watermelons, broad-leaved cormac, bobberry, stinky and some others.

• the final stage of the restoration process creates a tipchak-kovyl steppe in the North Chechen lowland consisting of tipchak, hair-shaped kovyl, sea wormwood, prostrate kochia, combed wheatgrass, noble yarrow and tamarix.

Abstract

The article presents a study that attempts to investigate the features of students' environmental behavior. The peculiarity of this work is the inclusion of some indicators of the digital trace of individuality (openness/closedness of the profile and the color scheme of the profile) in the analysis of the results obtained using valid methods characterizing students' attitudes to environmental issues. The authors trace the relationship between the indicators characterizing environmental behavior and the studied indicators of the digital trace of students' individuality. Also, in the process of analyzing the results obtained, a relationship was revealed between the age characteristics of students and the features of their profile in VK.

Keywords: digital trace of individuality, integrated individuality, environmental issues, digital environment, VK users, environmental behavior, student age

I. Introduction

Trying to analyze the digital trace of individuality, or as we propose from the point of view of the theory of integrated individuality of V.S. Merlin and the theory of polymorphic individuality of V.V. Belous [1] - the supra-status (digital) level of individuality, it is necessary to evaluate its profile in the social network according to available open parameters. In this study, we attempted to analyze the characteristics of the attitude to environmental issues in the student environment, on the one hand, and, on the other hand, to link these characteristics with some parameters of the digital trace of individuality - the openness or closedness of the profile in the social network and the predominant colors in the photographs that are available in the profile. This approach is relevant, since the actively developing digital environment makes its own adjustments to the structure of individuality [2]. Not so long ago - in the early 2000s, psychologists considered this environment, the environment of the Internet space exclusively as a resource that negatively affects the psyche. In studies, the Internet environment was considered addictive.

II. Methods

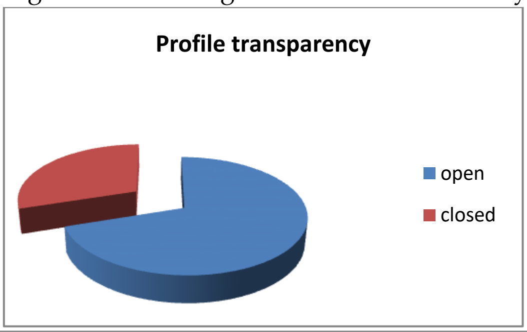
The study involved first-year students of the Institute of International Relations of the Federal State Budgetary Educational Institution of Higher Education "Pyatigorsk State University" - future journalists and specialists in international relations. The diagnostics were conducted in September 2024. We asked the respondents to provide a link to their profile on the social network during the diagnostic methods. Of the 123 students who passed the test, 98 provided this information. Another feature of this component of the study was that several students provided incorrect access to the profile. Thus, 86 people remained in the sample - 69 girls and 17 boys. The profile for analysis was characterized by 2 indicators - openness / closeness of the profile and the predominant color of photos, pictures, etc., which are available in the profile.

To diagnose attitudes towards environmental issues and manifestations of environmental behavior, we used valid diagnostic methods – the Method of Diagnosing Motivation for Interaction with Nature "Alternative"; the Scale of Environmental Concern and the Method of "Differential Emotions Scale" [3]. To process the obtained data, we used statistical data analysis.

At the final stage of the study, a comparative analysis of the obtained data and their interpretation was carried out.

III. Results

At the first stage, our goal was to characterize students' profiles on VK by two characteristics: openness or closedness of the profile and the predominant color scheme of the profile photo, which will indicate the emotional background of the digital trace of individuality.



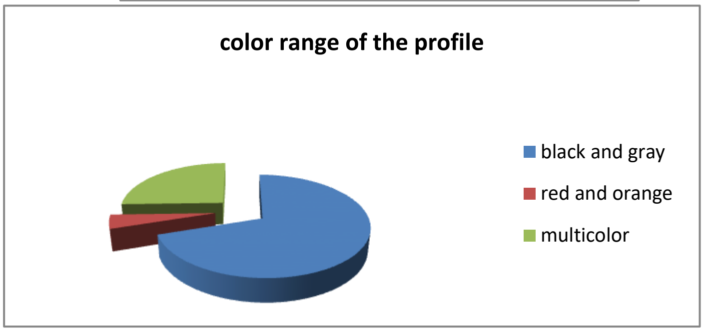


Figure 1: *Results of the analysis of profile openness/closedness and profile color scheme" (%)*

Of the provided VK profiles, 30% were closed. The remaining 70% are open and filled profiles. We assume that students exhibit extroverted behavior in the digital space - they are open to the digital environment and ready to interact. As for the color scheme, black or gray predominates in most profiles (77%). Red or orange predominates in 5% of cases, and in 28% of cases, there is a variety of colors and no dominance of any color. The predominance of black indicates an emotional state characteristic of the stage of adaptation to the university conditions, the presence of a certain stress characteristic of the transition from adolescence to young adulthood. Black in this situation is a desire for independence, resistance to external pressure and denial of any authorities. To this characteristic should be added the manifestation of aggression and depression.

In the further analysis, we will consider the results of diagnostics using methods that determine environmentally responsible behavior - the Method of Diagnostics of Motivation for Interaction with Nature "Alternative"; the Scale of Environmental Concern and the Method "Scale of Differential Emotions". In the analysis, we will trace the relationship between the obtained results and the features of the digital trace of individuality.

Fig. 2 shows the results of diagnostics using the Alternative method of diagnosing motivation for interaction with nature. In the sample under study, two types of motivation predominate:

aesthetic and cognitive. This fact indicates that respondents perceive nature as an object of beauty when actively interacting with it. High rates of this type of motivation are demonstrated by 68% of students with an open VK profile.

Also, high rates are presented in the cognitive type of motivation, which indicates the attitude to the environment as an object of knowledge in interaction with it. This type of motivation prevails in 30% of students with an open profile. It should be noted that 89% of students have a multi-color profile photo.

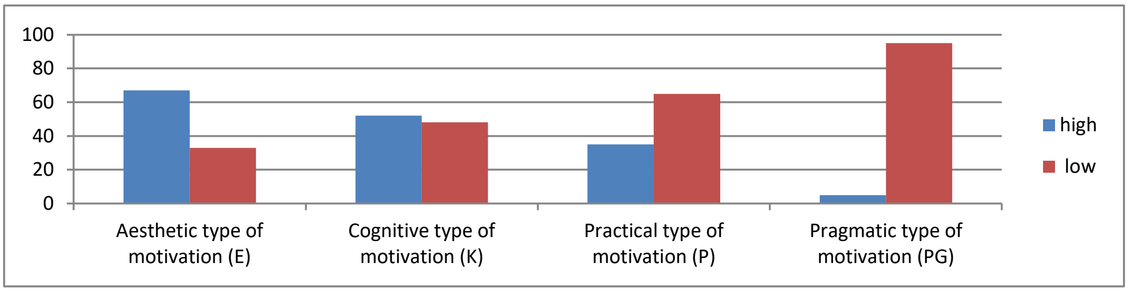

Figure 2: *Results of the Methodology for diagnosing motivation for interaction with nature "Alternative" (%)*

Fig. 3 shows the results of the "Scale of Environmental Concern" method. It is obvious that high scores were obtained for all scales, which indicates concern about the fate of animals, birds and the ecosystem as a whole, as well as concern about the impact of the consequences of environmental problems on children, people who live in the same region. A high level is also observed for the "Egoistic Concern" indicator - everything that concerns the consequences of environmental problems for one's own health, one's own lifestyle and future. Such scores indicate a high level of involvement in understanding the consequences of environmental problems in real life. Moreover, such data are shown by all representatives of this sample - students with open and closed profiles and with all types of color schemes in the profile.

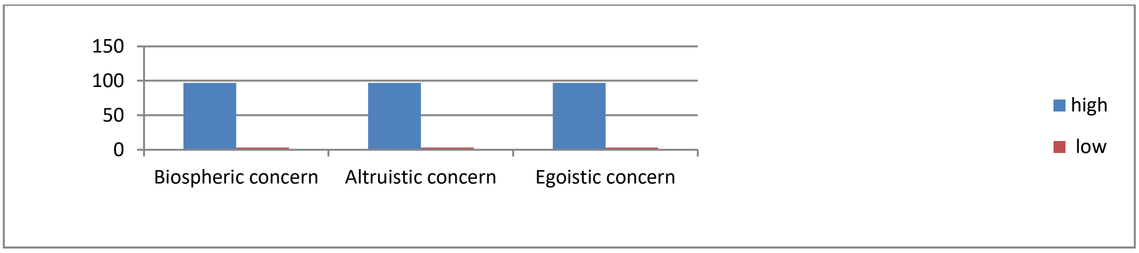

Figure 3: *Results for the Environmental Concern Scale Methodology (%)*

Based on the data obtained, we can state a high level of environmentally responsible behavior.

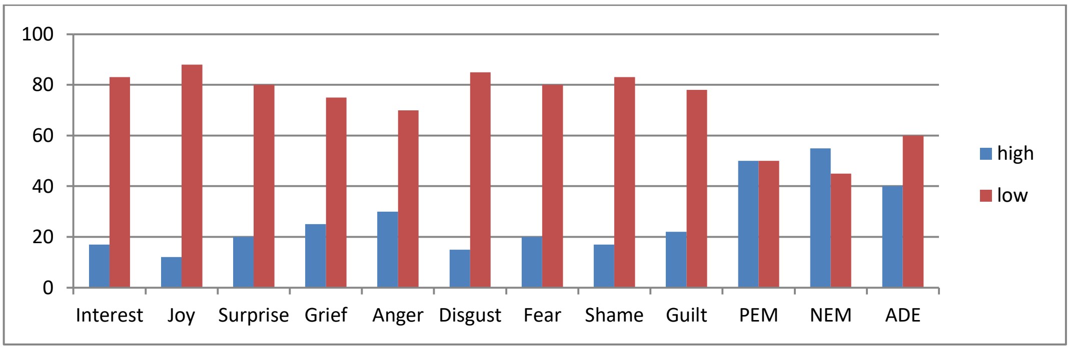

Figure 4: *Results for the "Differential Emotions Scale" method (%)*

The results presented in Fig. 4 determine the level of emotion that the subjects showed regarding the current situation. In the block of positive emotions, there is a predominance of low emotion in all indicators: "Interest", "Joy" and "Surprise". Comparing the data with the manifestation of the digital trace of individuality, and specifically in the prevailing color scheme - black and gray, there is a connection between the emotional state and the prevailing color of the profile. In the block of negative emotions, low values are recorded for all four indicators, which once again confirms the closeness and some emotional instability inherent in first-year students. In general, the general index of positive emotions and negative emotions are distributed approximately in equal shares between high and low indicators. At the same time, the picture is complemented by the predominance of the low level of the indicator " Anxious and depressive emotions ", which characterizes the predominance of environmental features over individual ones in the manifestation of emotions regarding the situation associated with the attitude to environmental problems.

IV. Discussion

The study by Ivanova I.V. and Konenkova N.V. examines the influence of the reflexive-value approach on the formation of environmentally responsible behavior of young people [4]. Scientists have proven the importance of interpersonal relationships and both general and environmental culture in the formation of environmentally responsible behavior. The study by Matovaya N.I and Shagarova L.M. highlights a very relevant and burning topic of our country's share - tourism and its development [5]. Their work examines the need for environmentally responsible behavior of tourists in nature conservation areas. This problem is considered within the framework of the contradiction between the need to develop domestic tourism and the need to preserve unique natural monuments of Russia. Demenshin V.N. in his "Review of Foreign Studies of Environmental Consciousness" [6] refers to the studies of I. Tilikidou and J. Zotos, who, based on the works of B. Schlegelmilch, developed an approach to describing environmental consciousness, in which they included all components of environmentally responsible consumer behavior, while the behavioral aspect includes pro-environmental purchasing behavior, pro-environmental behavior after purchase and environmental protection activities [7]. Summarizing the sources we have cited, we can state that environmentally responsible behavior in the student environment is not considered in psychological science.

In the aspect of the digital trace of individuality, Tulupyeva T.D. and Ivanova A.Yu. consider a psychological approach, which involves studying the manifestation of mental properties and characteristics of a person during communication and behavior on the network, taking into account that communication occurs within social groups, this approach is characterized as socio-psychological [8; 9; 10]. Gaidash O.V. in his study, describing modern approaches to the interpretation of the digital trace, states the fact that the features of these characteristics of individuality are used mainly by marketers [11].

From the point of view of the theory of integrated individuality by V.S. Merlin and polymorphic individuality by V.V. Belous [12], the digital trace of individuality (the data that can be openly available in the digital environment) has not yet been considered as a supra-status level of integrated individuality. In this paper, we postulate a new approach to the study of the holistic individuality of a modern person.

Abstract

The article is devoted to regional climate changes in the territory of Azerbaijan and the study of water resources of the Karabakh region. Based on the actual multi-year temperature and precipitation data, the dynamics of changes of the specified parameters for the years 2007-2022 compared to the multi-year norm were evaluated by regions and different altitude intervals. An increase of 1.2^{0}C in the average multi-year temperatures across the republic, and a decrease of precipitation to 26 mm was determined.

The water resources of the rivers of the Karabakh region were assessed using the newly developed Complex Water Balance Method (CWBM). This method is based on the principle of estimating water resources, taking into account the complex flow-forming factors. For this purpose, satellite data, GIS and other multifunctional computing technology were used. In 1998, the water resources of the Karabakh region's rivers were 2.13 km^3, but in 2022 it was 1.80 km^3, or a decrease of 15.2% was observed.

Keywords: climate changes, temperature, precipitation, CWBM method, water balance, water resources

I. Introduction

Provision of water to the population and economy, purposeful and economical use of water resources have always been priority directions in water policy. The aggravation of water-related problems has made it necessary to pay more attention to this spher than before. Conducting relevant scientific research on water problems is considered one of the priority scientific researches, being one of the always relevant issues in hydrology. Because there is a big difference between the demand and supply of water in the Republic of Azerbaijan, where irrigation agriculture and the population's demand for water dominate. In recent times, due to the influence of global climate changes, there have been changes in the world's water resources, especially in surface and underground waters, in the annual flow and regime of rivers, which of course also manifests itself in the territorial rivers of Azerbaijan. Thus, in the annual flood and high flows period of the country's rivers, their maximum water consumption decreases, while in the winter low flows period flows, on the contrary, there is an increase. As a result of the reforms carried out in Azerbaijan, a strong socio-economic potential has been created in the country. However, the depletion of natural resources against the background of global climate change creates additional problems in the implementation of reforms. For this reason, scientific directions and methods should be determined so that research does not lag behind the general pace of development of reforms. Current conditions require the assessment of natural resources with more modern, sensitive and operational methods that can respond to any changes [1, 3, 9]. Our proposed CWBM method is one of these types of methods. CWBM was developed on the basis of the leading water balance methods available in the world, taking into account their synthesis and the specific characteristics of the nature of Azerbaijan [6, 8].

II. Materials and methods

Satellite images of territory, digital elevation model (DEM) and hydrometeorological observation data of different years were used as initial input data for conducting the research. The main source of climate data is the measurement-observation data of the Ministry of Natural Resources and Ecology of the Republic of Azerbaijan. To determine the types of landscape, land cover, and moisture levels, multispectral space images of the terrain from different periods were processed using normalized difference indices (NDI-Normalized Difference Indices). Considering the content of the research work, difference indices of vegetation (NDVI, SAVI), bare soil and bedlands (BSI), erosion (NDBal), soil salinization (NDSI), residential and build-up (NDBI), urban (UI) , water (NDWI), drought (NDDI) and moisture (NDMI) were preferred in the study. The elevation, slope and aspect values of the study area were determined using DEM, and the morphometric indicators of the rivers using the Hydrology, Surface and Density software of the ArcGIS program. To select similar data and get more reliable correlations between components, Modern Analogue method and Multiple linear regression equations were used.

III. Results and discussion

Since regional climate changes have a greater impact on the water balance elements and annual flow of rivers, in order to study the dynamics of temperature and precipitation changes in the territory of the country, their higher intervals than the multi-year norm and by regions were studied, and some results are given in tables 1, 2 and 3, respectively [4, 5].

Table 1: *Changes of temperatures in the territory of Azerbaijan in 2007-2022 at different height intervals relative to the multi-year norm (1961-1990), T°C*

Periods	Elevation intervals, m					By the republic
	≤ 0	1-200	201-500	501-1000	> 1000	
Multi-annual norm, 1961 -1990	14.6	14.3	13.3	11.9	7.8	12.3
Medium perennial, 2007-2022	15.5	15.7	14.5	12.9	9.2	13.5
Relatively increase to the perennial norm	+1.0	+1.4	+1.2	+1.0	+1.4	+1.2

As can be seen from Table 1, the temperature increase in the territory of the country compared to the multi-year norm is +1.2^{0}C in the period 2007-2022. The greatest increase in elevation intervals is at 1-200 m and >1000 m elevations (+1.4^{0}C). However, the high annual temperature increase for the period 2007-2021 was 2010 (+1.3^{0}C), 2012 (+1.3^{0}C), 2014 (+1.3^{0}C), 2015 (+1.5^{0}C) , 2018 (+1.8^{0}C), 2019 (+1.5^0 C) and 2021 (+2.1^{0}C). In general, the years 2018 and 2021 have gone down in history as the hottest years in the world during the entire observation period, and this has also shown itself in Azerbaijan.

Table 2: *Temperature changes in the years 2007-2022 compared to the 1961-1990 period in different regions of the Republic of Azerbaijan, T°C*

Periods	Regions						By the Republic
	Absheron-Kobustan	Lankaran-Astara	Greater Caucasus	Lesser Caucasus	Kur-Araz	Nakhchi-van AR	
Multi-annual norm, 1961 -1990	14.5	12.9	10.7	9.2	14.3	12.4	12.3
Medium perennial, 2007-2022	15.5	13.9	11.5	10.5	15..6	13..7	13..4
Relatively increase to the perennial norm	+1.0	+1.0	+0.8	+1..3	+1.3	+1.3	+1..2

As can be seen from Table 2, the largest temperature increase by region is in Kura-Araz and the Lesser Caucasus (+1.3^{0}C), in Nakhchivan AR, and the least in the Greater Caucasus is +0.8^{0}C. In 2018 and 2022, a sharp increase in temperature was observed in all regions. Thus, in 2018, +1.4^{0}C in Absheron-Kobustan, +1.7^{0}C in Lankaran-Astara, +1.1^{0}C in the Greater Caucasus, +1.6^{0}C in the Lesser Caucasus, 1.9^{0}C in Kur-Araz, +2.8^{0}C in Nakhchivan AR. But the air temperature has risen by +1.8^{0}degrees across the entire republic.

In 2021, the average annual temperature for the republic increased by 2.1^{0}C, in 2022 by 2.0^{0}C, and the largest increase occurred in the Lesser Caucasus by 2.5^{0}C.

This increase in regions reflects its regularity for the multi-year period (2007-2022). In the Nakhchivan region, which is distinguished by its warm continental climate, the temperature increase compared to the multi-year norm was observed at a record level: +2.8^{0}C. In precipitation (Table 3), a weak decrease was observed compared to the multi-year norm, and it is interesting that, although there was an increase or decrease in all altitude intervals during this period, only in the altitude interval of 200-500 m, a decrease in precipitation was recorded in all years. In 2014-2017, a decrease was observed in all height intervals, including precipitation across the country. In 2011 and 2016, a maximum increase in precipitation was observed at all altitudes (except 201-500 m altitude), including the republic.

The study of regional climate changes in Azerbaijan, including the evaluation of river water resources in the occupied Karabakh territory, where systematic hydrometeorological observations have not been carried out for nearly 30 years, is proposed as the main research goal in the article [2, 7, 10]. Thus, against the background of modern climate changes, the study of the water resources of the Karabakh territory, re-estimation and improvement of water demand are considered more important from the point of view of scientific-research directions.

Currently, water balance methods are preferred in estimating water resources [3, 6, 9]. New advanced methods are created by internal modification of leading hydrological models, called "base methods", or by their synthesis and hybridization. Based on the current trend, a new operational-interactive method–Complex Water Balance Method (CSBM) has been proposed to assess the water balance and water resources of regional rivers. With the new method, the research process is carried out entirely through satellite images and GIS technologies. The main scientific principle of CWBM is the assessment of water resources through runoff coefficients, which include the influence of complex factors that shape the river flow. It is known that the greater the participation of factors affecting the flow formation, the more accurate the results. The participation of complex flow-forming factors was taken into account in CWBM. Even for the first time, new predictors were added to the calculations, such as the vegetation density, slope degree, horizontal fragmentation of the territory, exposure of slopes, humidity level. Among the innovations of CWBM, the application of new and different scientific approaches such as acceptance of the soil-air-water environment as a single mechanism, Counter-approach technology and Analogue method are also included. As a result, it is possible to calculate water resources with high accuracy without space-time limitation and dependence on observational data.

Table 3: *Precipitation changes in different altitude ranges in Azerbaijan for the period 2007-2022, mm*

Years	Heights, m					By the republic territory
	≤ 0	1 - 200	201-500	501-1000	>1000	
Norm	334	327	478	534	639	476
2007	-21.0	-8.0	62.0	89.0	25.0	+16.0
2008	+5.9	-29.0	-171	147.0	+5.0	-31.0
2009	+38.0	+69.0	-7.0	+17.0	+11.0	+6.0
2010	+30.0	+69.0	-28.0	+232	-20.0	+51.0
2011	+178	+124	-19.0	+288	+143	+87
2012	+14,0	-29,0	-130	+94.0	+51,0	-23,0
2013	+29.0	- 44	- 186	+ 78.0	- 18.0	- 45.0
2014	-11.0	-60	-117	-11	-82.0	-70.5
2015	+10.0	+32.0	-55.0	+33.0	-31.0	-42.0
2016	+118	+108	-12	+151	+124	+110
2017	-40.3	-38.6	-260	-41.2	-125	-101
2018	+6	-32	-7	+172	+10	-21
2019	+34	+6.0	-22.0	+8.0	-95.0	-50.0
2020	+20.9	-63.5	-141	+55.7	-43.7	-51.2
2021	-119	-80	-90	49	-140	-134
2022	+16,0	-10	-80	+75	-25	-27
Changes from norms	+14.5	-7.5	-77.0	+67	-22.0	-26.5

Research in this type of methods covers 4 main principles: applicability, operativeness, interactivity and prognosticity. Applicability - characterizes the maximum practical orientation of scientific results. Operativeness - refers to the faster use of the results obtained in order for scientific research not to lag behind the pace of economic development. Interactivity - is the adequacy of research against variable factors, prognosticity - is the assessment of changes in terms of possible consequences that may occur in the future. In terms of ensuring flexibility and interactivity in hydrological research, the most important tool is obtaining the necessary information about the research area without physical contact. Expanding the use of satellite images of the area, giving preference to remote sensing and flexibility methods are presented as an important scientific necessity in modern approaches. On the other hand, since it takes a lot of time to restart measurement and monitoring works on climate and flow quantities, the obtained results can lead to delays from a practical point of view, and lose scientific-practical and economic importance. Therefore, the minimization of observations and experimental experiments is also an important factor in terms of flexibility and interactivity. Expanding the use of modern technologies in the process of research data processing and calculation is one of the aspects considered as the foundation of this process. In this type of scientific approaches, various calculation, comparison, probability and prioritization technologies are highlighted with GIS and other technical means.

Thus, the advantages of the new methods are the following important principles:

1. Conducting research through satellite images without physical contact;
2. Fast, interactive and accurate calculation mechanism;
3. Lack of dependence on observational data;

4. Not imposing time-space and size restrictions;
5. Consideration of the influence of complex factors;
6. The effect of each factor on the flow can be given separately and together in a quantitative expression;
7. In addition to climate factors, landscape and anthropogenic effects are calculated separately;
8. Multivariate prediction line through 3-stage (past, present, future) research;
9. Air, soil and water space are considered as a single environment.

Among the innovations that attract attention in the process of developing the CWBM, for the first time in the GIS environment, the selection of similar geo-spaces based on complex factors, several different interpolation methods and the application of Counter-approach technology, including the inclusion of scientific principles such as recovery of unknown factors.

The Analogue method, that is, the principle of finding similarities in terms of physical and geographical conditions between basins with data and those without observations, is one of the widely used methods in hydrology. The more similar conditions are between geo-spaces, the more successful it is to calculate river flow and water resources. Flow formation is a very complex process. Until now, due to the influence of several factors, the condition of flow formation and the assessment of water resources did not allow obtaining very accurate results. Long-term experiments conducted in river basins using basic methods have also shown that the more similar the physical-geographical conditions in which the flow is formed, the closer the flow coefficients are to each other. At present, scientific and technical achievements have created conditions for a more in-depth analysis of flow formation and precipitation-flow process. These results were obtained based on the data of numerous measuring stations with different natural conditions, as well as artificial experimental experiments carried out in the basins.

In the research process, the correction process of flow coefficients with CWBM was carried out according to the following algorithm:

1. Daily climate and flow data of hydrometeorological observation points located in river basins with different physical and geographical conditions are collected.
2. Data on other complex factors influencing flow in these river basins is obtained through satellite images.
3. Available hydrometeorological observation data and indicators of flow-forming factors are collected and processed together in the ArcGIS database.
4. Based on actual observation and space data, the regional representativeness of climate and flow data in river basins is investigated.
5. The specific physical and geographical conditions corresponding to the flow quantities are defined.
6. Possible situations involving the combined effect of complex climate, landscape and other factors are considered and different runoff coefficients are found for each situation.
7. Correspondence of runoff coefficients is determined, same (or close range) coefficients are grouped and corrected.
8. The applicability of the obtained coefficients to similar places without data is checked and the most reliable results are selected.

In the CWBM method, the influence of factors on the flow is evaluated both separately and together in a complex manner. Not only the factors themselves, but also their intraspecies diversity, different quantitative indicators are necessary when determining runoff coefficients. For example, the vegetation density, the degree of soil moisture, the population settlement level, different slope and height gradations, etc. runoff coefficients are also determined for indicators. Each different situation manifests itself as a new runoff coefficient. The multiplicity of runoff coefficients is due to the consideration of complex effects and each specific situation. In order to facilitate the use of the method, the runoff coefficients are given on the basis of more important and variable factors, which actually include the influence of other factors directly or indirectly.

The application of CWBM is suitable for areas with any physical-geographical conditions and where observations are not made, without time-space restrictions. The evaluation of the water resources of the Karabakh region, which is distinguished by its extreme conditions, through CWBM is the basis of the research work. Due to the fact that it is under occupation, measurement works and researches have not been carried out in the region for many years. However, the research process was carried out with high accuracy, since the advantages of the new method allowed to eliminate these and other shortcomings. The research period covers the years 1998-2022 (figure 1).

Figure 1: *Location of the study area*

The water balance elements and water resources of the Karabakh region for the years 1998-2022 were investigated with satellite images and multifunctional GIS processing. The results obtained using CWBM method are reflected in Table 4.

Table 4: *Comparison of changes in the water balance components and water resources for 1998-2022*

Components of the water balance	1998	2021
Atmospheric precipitation, mm	572	547
Air temperature, C°	8.28	8.51
Potential evaporation, mm	802	829
Factual evaporation, mm	415	423
Humidity coefficient,	0.71	0.66
Maximum soil water retention, mm	1163	1189
Initial abstraction, mm	313	331
Actual soil moisture, mm	196	217
Hydrologic losses, mm	495	478
Rational runoff coefficient	0.303	0.290
Total runoff, mm	158	143
Surface runoff, %	48.9	47.9
Baseflow, %	51.1	52.1
River discharge, m^3/sec	67.5	57.3
Water resources, km^3	2.13	1.80

During 1998-2022, the change of water resources of the administrative regions included in the Karabakh region and the role of climate and landscape changes in this process were also assessed separately (Table 5).

Table 5: *The role of climate and other factors in the change of water resources of the Karabakh region in 1998-2022*

Regions	Water resources changes		İmpact of factors			
			Role of climatic factors		Role of other factors	
	increase-decrease	%	increase-decrease	%	increase-decrease	%
Terter	⬆	+10.9	⬆	+1.15	⬆	+9.75
Agdam	⬇	–9.47	⬇	–14.6	⬆	+5.13
Fuzuli	⬇	–4.86	⬇	–9.54	⬆	+4.68

Kubadlı	⬆	+7.91	⬆	+4.37	⬆	+3.54
Zengilan	⓿	0.00	⬇	–9.33	⬆	+9.53
Karabag	⬇	–15.2	⬇	–9.54	⬇	–5.66

IV. Conclusions

1. A new hydrological method – CWBM (Complex Water Balance Method) was used to assess the water balance of the area and the water resources of the rivers. CWBM is an operative-interactive and highly accurate method. Through CWBM, the whole research process and assessment can be performed without physical contact with the area, time-space limitations, and dependence on observational data.

2. Water resources of the Karabakh region using of the CWBM, were estimated at 2.127 km^3 in 1998 and 1.804 km^3 in 2021. In total, over the specified period, water resources decreased by 15.2 %.

3. According to assessment, the average total runoff coefficient of the Karabakh rivers in the period up to 2022 was equal to 0.2625; that is, 73.75 % of precipitation did not participate in the runoff formation. The fraction of surface runoff was 47.9 %, and baseflow – 52.1 % in total feeding of regional rivers.

4. It was determined that out of this 9.54 % decrease in water resources in 1998-2022 accounts for climatic, and 5.66 % - for the role of human activities and other factors.

5. Serious regime variability is observed in the rivers of the research area. Thus, due to the influence of regional climate changes, the annual runoff decreases, and the runoff of the winter low-water period increases. Due to the decrease in the volume of flood and torrential flows, their maximum water discharge (Q_{max}, m^3/sec.) also decreases.

Abstract

This study explores the influence of climatic conditions on the adaptation of the cardiovascular system of students to physical activity, emphasizing the implications for sustainable development in education. As climate change continues to alter environmental conditions, understanding how these factors affect students' physiological responses to physical exercise becomes crucial. The research highlights the importance of incorporating climate-responsive training programs in educational institutions to enhance students' cardiovascular health and overall well-being. By addressing the interconnection between climatic influences and cardiovascular adaptation, the study aims to provide insights into developing sustainable educational practices that promote physical fitness and health resilience among students in varying climatic contexts. The work studied the functional state and assessed the functional reserves of the cardiovascular system in university students at rest and during adaptation to muscle load. Male and female students of the higher educational institution participated in the study of the functional reserves of the cardiovascular system. Blood pressure, heart rate and a number of indices characterizing the functional state of the cardiovascular system were examined. The study of these hemodynamic parameters was carried out at rest and after a functional motor test. It was found that the type of response to dynamic muscle load in male and female students is normotonic. According to the Ruffier index, male and female students have a satisfactory functional state of the cardiovascular system. The values of the adaptation potential indicate the tension of the adaptation mechanisms and some decrease in the physiological reserves of the cardiovascular system. Minor differences were noted between the sexes in adaptation to muscular load (Ruffier test): females had average performance, while males had good performance.

Keywords: cardiovascular system, blood pressure, heart rate, adaptation, muscle load, hypoxia, hypokinesia, student, climatic conditions, cardiovascular adaptation

I. Introduction

In recent years, the impact of climatic conditions on human health has gained increasing attention, particularly in the context of physical activity and exercise. As students represent a vital segment of society engaged in physical education, understanding how environmental factors influence their cardiovascular adaptation to exercise is essential. The cardiovascular system plays a pivotal role in regulating physical performance, and its efficiency is significantly affected by external conditions such as temperature, humidity, and altitude.

Climatic variations can alter how the body responds to physical exertion. For instance, extreme heat can lead to dehydration and heat-related illnesses, while cold conditions may affect circulation and increase the risk of hypothermia. As climate change progresses, educational institutions must consider these factors to foster a safe and effective environment for student athletes and physically active individuals.

This study aims to examine the intricate relationship between climatic conditions and the cardiovascular responses of students during physical activity. By focusing on these dynamics, we can better understand the importance of developing adaptive strategies that align with the principles of sustainable development in education. Incorporating climate-aware practices in physical education can not only enhance students' health outcomes but also promote awareness of environmental issues, ultimately contributing to a more sustainable future for communities.

The findings of this research will serve as a foundation for educators, policymakers, and health professionals to create more effective physical education programs that prioritize cardiovascular health while adapting to changing climatic conditions. By acknowledging the interplay between climate and health, we can work towards fostering resilience among students in the face of environmental challenges, ensuring their well-being and capacity to thrive in diverse settings. Studying at a higher educational institution causes certain functional and structural changes in the body of young people studying. Long-term physical inactivity in higher educational institutions has a significant impact on the functional state of the cardiovascular system in male and female students. The functional state of the cardiovascular system can act as a key factor in assessing the adaptive reactions of the human body [5]. It is believed that its functional indicators are a universal indicator of the adaptive activity of the human body to environmental factors [11, 12].

The functional state of the cardiovascular system is assessed by studying the parameters of hemodynamics at rest [7]. Assessment of the cardiovascular system at rest does not allow for a full characterization of the functional state. Functional tests are used for this purpose . Functional tests with physical activity lead to activation of neurohumoral mechanisms of regulation of the cardiovascular system, increased oxygen transport, increased respiration rate, and the occurrence of tissue hypoxia in the cardiac and skeletal muscles [4]. In poorly adapted and untrained people, adaptation to muscle activity occurs mainly due to an increase in cardiac output. Cardiac output in such people increases due to an increase in heart rate [4].

When studying the work of the heart and cardiovascular system, a number of parameters and indices are used [2]. In addition to the common parameters - pulse, heart rate, blood pressure, minute blood volume, cardiac output, various indices are often used - the Ruffier index , the Robinson index, indices characterizing the inotropic and chronotropic reserves of the heart muscle [2].

The study of regional features of adaptation of the circulatory system and heart to dosed functional motor tests in young students is of theoretical and practical interest.

The aim of the work: to assess the functional state of the adaptive mechanisms of the cardiovascular system of students in response to hypoxia caused by dynamic motor load.

II. Methods

Students of the educational institution were involved in the study of the parameters of the cardiovascular system. This work involved male and female students of the Biological and Chemical Faculty and the Agrotechnological Institute of Grozny. The age of the students ranged from 21 to 23 years, which corresponds to mature age, the first period. At the time of the examination, male and female students had no complaints about the state of the cardiovascular system. They gave their verbal consent to participate in the study. Second-year female master's students also took part in the study. Only female master's students were examined, since there were no males among the master's students at the university.

We conducted a functional study of the cardiovascular system in response to physical activity using the Ruffier test, which is often used to assess the functional state of the cardiovascular system. The Ruffier test involves performing 30 squats in one minute.

At rest, blood pressure and heart rate were measured. To measure them, we used an automated device for measuring blood pressure and heart rate – MT-40 (USA). This device automatically measures the pulse and two types of pressure – systolic (BPs , upper) and diastolic (BPd , lower) pressure. Pulse pressure (BPp) was calculated as the difference between the maximum and minimum pressure of the subject. After performing the Ruffier motor test, the subjects ’ blood pressure and heart rate were immediately measured.

We studied the following parameters: heart rate, blood pressure (systolic, diastolic, pulse, average), pulse at rest and after a minute of Ruffier's robe . We also determined several different indices - the Kerdo index, the Robinson index, the Ruffier index and the adaptation potential index according to R. M. Baevsky.

Heart rate and blood pressure measurements were taken at rest (15 seconds), after the Ruffier test (15 seconds immediately after the test) and for 15 seconds at the end of the first minute of recovery.

The value of the adaptation potential was calculated at rest, after performing the Ruffier test and after a minute of recovery.

For statistical processing of the results of the study of blood pressure, heart rate and various indices, including the value of the adaptation potential, the Paired Student's criterion was used. The results of the study were processed by the computer program " Biostatistics ".

IV. Discussion

Cardiovascular system parameters at rest and after the Ruffier test . Systolic pressure in male and female students increased significantly after the Ruffier test (Table 1, Fig. 1). According to literature, systolic pressure increases after physical exertion [2, 5].

Table 1: *Systolic pressure (mmHg) in subjects examined after the Ruffier test*

Subjects	State of rest	Ruffier's test	Recovery, 1 min
Girls	118.6±2.32	133.2±2.88**	119.6±2.64
Young men	121.3±2.91	142.4±3.24**	122.3±3.42

*- $p< 0.05$

Unlike systolic pressure, diastolic pressure does not undergo statistically significant changes in both male and female students after the Ruffier test (Table 2, Fig. 2). According to literature [2], diastolic pressure in response to physical activity either increases slightly or does not change immediately after the load. After a fairly short period of time - less than 3 minutes after the load - this indicator returns to the original value or even decreases. As can be seen from Table 2, we note this pattern in both male and female students.

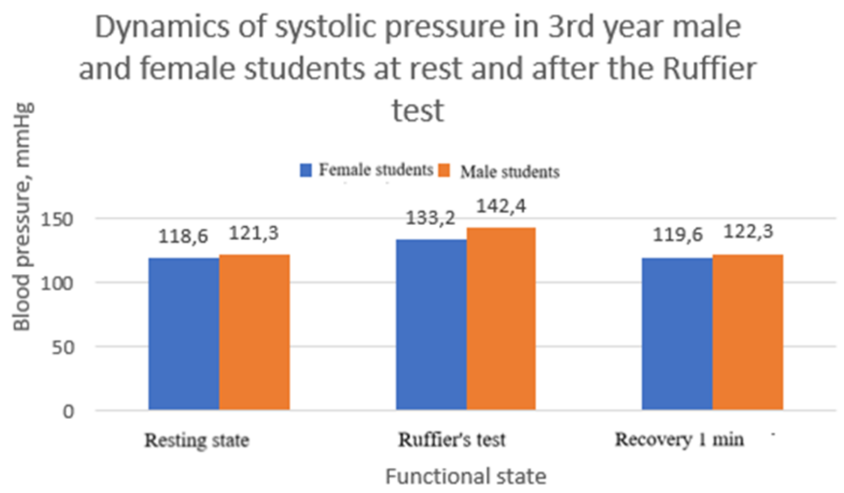

Figure 1: *The nature of changes in systolic blood pressure in 3rd year students after performing a functional motor test*

Table 2: *Diastolic pressure (mmHg) in male and female students after the Ruffier test*

Subject	State of rest	Ruffier's test	Recovery, 1 min
Girls	72.8±2.05	76.4±2.23	68.2±1.72
Young men	74.5±2.11	80.3±2.21	73.7±2.41

p>0.0

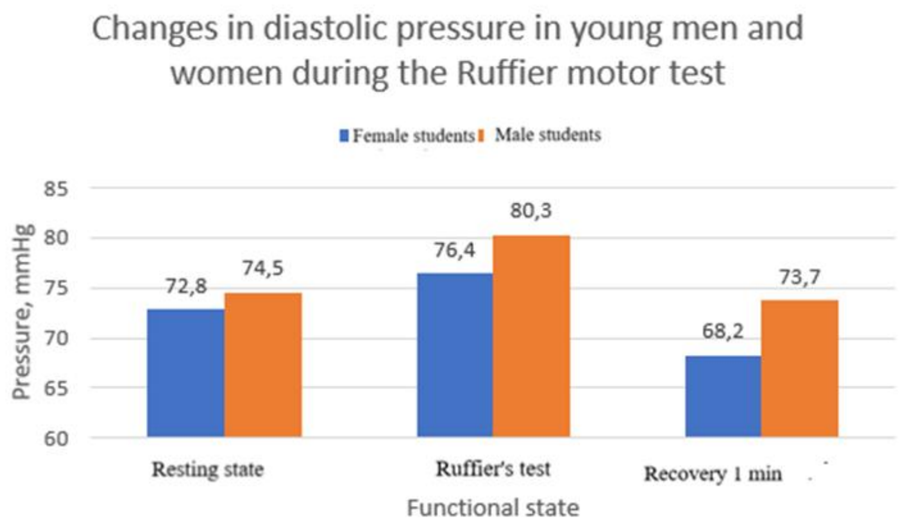

Figure 2: *Lower arterial pressure in 3rd year male and female students after performing the Ruffier test*

It should be noted that the World Health Organization provides the following categories for assessing blood pressure (regardless of gender): systolic pressure of less than 120 mm Hg is considered normal, and less than 130 mm Hg is considered normal systolic pressure. The following categories of assessments are accepted for diastolic pressure: - normal (less than 80) and normal (less than 85). According to these data, the pressure of the surveyed male and female students (general group value) can be considered normal. At the same time, individual fluctuations in blood pressure among male and female students have a wide range.

According to E. A. Ryazanova and L. A. Girenko [9], an increase in heart rate after physical exercise (Martine's test) by more than 31 units indicates an unsatisfactory state of the cardiovascular system. In the present study, the subjects performed physical exercise in the form of the Ruffier test . In those examined by us, the heart rate after the Ruffier test increases quite high, although it does not exceed the limit of 31 units (Table 3, Fig. 3). Moreover, performing the Ruffier test causes a reliable increase in the heart rate (Table 3, Fig. 3).

Table 3: *Heart rate (bpm) in male and female students after the Ruffier test*

Subjects	State of rest	Ruffier's test	Recovery, 1 min
Girls	80.1±2.44	107.5±3.22**	88.7±3.55
Young men	73.4±2.32	98.6±3.65**	79.9±3.67

** p< 0.02

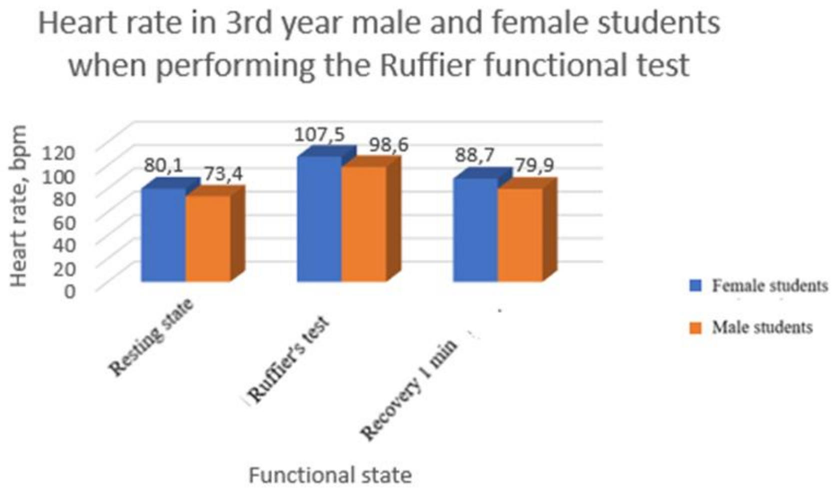

Figure 3: *Heart rate dynamics in 3rd year students after short-term physical activity*

An increase in pulse rate by 27.4 units was noted in girls and by 25.2 units in boys. Consequently, it can be concluded that the organism and cardiovascular system of the students we examined are satisfactorily adapted to physical activity.

Evaluation of the functional state of the cardiovascular system by indices at rest and after performing the Ruffier test . At rest, the Kerdo index in female students indicates the prevalence of sympathetic influences on the work of the heart. As can be seen from Table 4 and Figure 4, girls have a more pronounced sympathetic effect on the activity of the heart and blood circulation: their CI is +9 at rest. Kerdo index values from -10 to +10 are considered normative. Positive CI values indicate the prevalence of sympathetic influences on the work of the heart. In young men, the CI value is negative (-1.5) (Table 4), which indicates a parasympathetic effect on the work of the heart at rest.

After performing the test In Ruffier , both in girls (+29 c.u.) and in boys (+18.5 c.u.), the influence of the sympathetic branch of the autonomic nervous system increases. The values of the Kerdo index after the load and a decrease in its value after 1 minute indicate a satisfactory state of the cardiovascular system of male and female students. At the same time, sympathicotonia is more pronounced in female students and it persists after 1 minute of recovery. In young men, sympathicotonia is noted after the load, and normotonia after a minute of recovery . Female and male individuals responded differently to physical activity.

Table 4: *Kerdo index (cu) in male and female students after the Ruffier test*

Subjects	Peace	Ruffier's test	Recovery, 1 min
Girls	0.091 (+9 USD)	0.29 (+29 USD)	0.231 (+23.1 USD)
Young men	-0.015 (-1.5 USD)	0.185 (+18.5 USD)	0.077 (+7.7 USD)

p>0.05

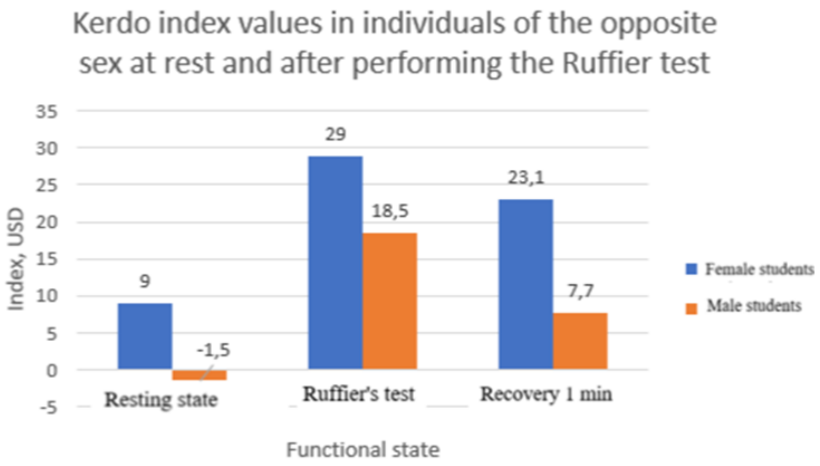

Figure 4: *Changes in the Kerdo vegetative index in students and third-year students*

Analysis of the functional state of the cardiovascular system using the Robinson index revealed the following features (Table 5, Fig. 5). The Robinson index values for girls were - 94.9 c.u., and for boys - 89.0 c.u. For girls, this indicator exceeded the standard limits of the index in a state of rest (85-94 c.u.), corresponding to the average functional state of the cardiovascular system [10].

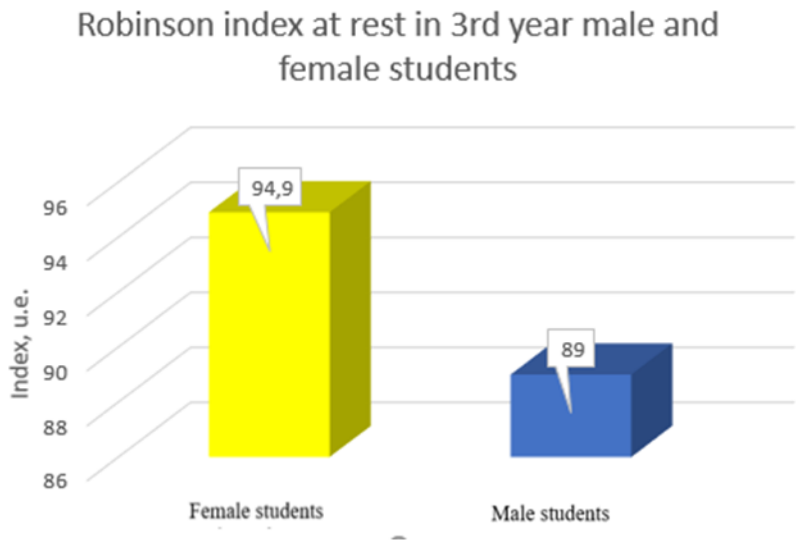

Figure 5: *Comparison of Robinson indices in individuals of the opposite sex. The Robinson index evaluates the functional state of the cardiovascular system at rest.*

As can be seen from Table 5, the IR indicators of female students were at the upper limit of the average functional state. The girls showed a slight decrease in the functional capabilities of the circulatory system.

Table 5: *Robinson index at rest in male and female students*

Floor	IR	Meaning
Girls	94.9 (cu); The upper literary limit of the average functional state of the cardiovascular system is 94 (cu).	Upper limit of the average functional state of the cardiovascular system. Some decrease in the functional capabilities of the cardiovascular system
Young men	89.0 (cu); The upper limit of the average functional state is equal to 94 (cu).	The value falls within the limits of the average functional state of the cardiovascular system. Average functional capabilities of the cardiovascular system

Ruffier index allows us to draw a conclusion about the state of the functional reserves of the cardiovascular system after performing a physical load. According to our data, the students we examined had average Ruffier index values . Thus, for girls its value was 7.63 c.u. , and for boys 5.19 c.u. (Table 6, Fig. 6). The literary norm of more than 15 c.u. indicates low reserves of the cardiovascular system.

Physical activity allows us to identify the features of the functioning of the circulatory system, hemodynamic parameters that are hidden when examining a person at rest. Physical activity is considered a stress factor for the body. It causes hypoxia in the cardiac and skeletal muscles [4]. The Ruffier index allows us to adequately assess the adaptive capabilities of the body, the circulatory system in response to muscle activity.

Table 6: *Ruffier index in male and female students*

Floor	IR values, c.u.
Girls	7.63 (from 7 to 9 – average heart performance [8]
Young men	5.19 (4 to 6 – good cardiac performance in response to physical activity [8]

Ruffier index in persons of the opposite sex, calculated based on changes in the parameters of the cardiovascular system after physical exercise

The magnitude of the adaptation potential at rest and after the Ruffier test .

AP is an integral indicator that takes into account the parameters of physical development and indicators of the cardiovascular system [3].

7 and Figure 7 below show the values of the adaptation potential of male and female students. For female students, the AP was 2.24 c.u., and for male students, it was 2.21 c.u. These values were determined in a state of rest.

According to some authors [1, 3], AP values below 2.6 c.u. are considered satisfactory adaptation of the circulatory system. In the male and female students we examined, AP at rest did not exceed this value. However, after performing the Ruffier test, the AP value rose above 2.6 c.u. (Table 7, Fig. 7). This AP value corresponds to the tension of the adaptation mechanisms. The reason for this is clear: physical activity causes an increase in blood pressure and heart rate. And AP is closely related to the parameters of the cardiovascular system and is calculated based on three of its parameters - systolic and diastolic pressure and pulse. At the same time, the AP values were higher in absolute value in female students, which may indicate a less pronounced adaptation to muscle loads in them compared to male students.

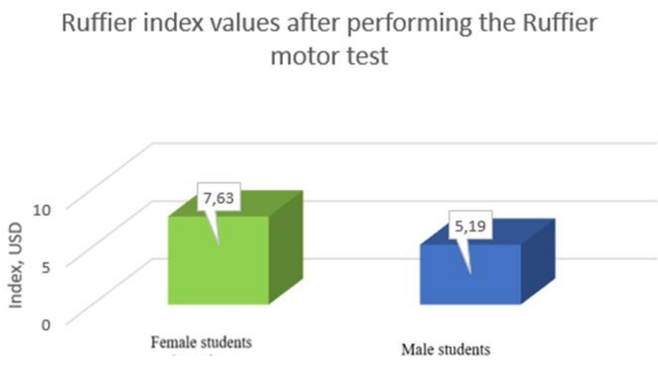

Figure 6: Ruffier index in male and female students

However, according to other authors, there are other limits for the AP values and their interpretation. They are most often found in the literature. In particular, the AP value of up to 2.10 c.u. is accepted as satisfactory adaptation and indicates sufficient functional reserves of the circulatory system. The functional stress of the adaptation mechanisms corresponds to AP values from 2.11 to 3.20 c.u. AP values from 3.21 to 4.30 c.u. are unsatisfactory adaptation, expressed in insufficient adaptability to physical activity, and finally, a breakdown of adaptation, corresponding to AP values of more than 4.30 c.u., a sharp decrease in the functional capabilities of the cardiovascular system [6]. According to this author, the AP values of our male and female students correspond to the stress of the adaptation mechanisms even at rest. After loading, the AP values increase even more, although they correspond to the state of tension of the adaptation mechanisms, that is, they are in the range from 2.11 to 3.20 conventional units.

Table 7: *The magnitude of the adaptive potential of male and female students studying in senior years*

Floor	AP at rest, c.u.	AP after Ruffier's test , c.u.	AP after 1 min recovery, c.u.
Students	2.21±0.176	2.82±0.210	2.34±0.176
Female students	2.24±0.195	2.86±0.193	2.38±0.182
r	>0.05	>0.05	>0.05

p>0.05

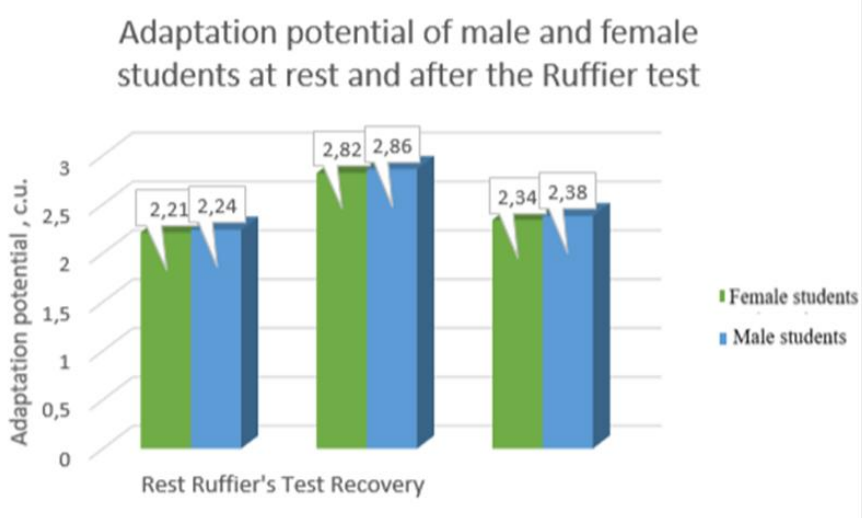

Figure 7: *The magnitude of the adaptation potential in individuals of the opposite sex at rest, after performing the Ruffier test and one minute of recovery*

No statistically significant differences in the magnitude of AP between male and female students were found at rest and after exercise.

Thus, the functional state of the cardiovascular system in 3rd year male and female students can be characterized as satisfactory. Physiological reserves of the body and cardiovascular system in male and female students are characterized by average functional capabilities. At the same time, students demonstrated higher physiological reserves of the cardiovascular system. In general, males are more adapted to muscle loads and to hypoxic conditions that occur in the cardiac and skeletal muscles during dynamic muscle loads.

Assessment of the functional state of the cardiovascular system of graduate students based on the results of the Ruffier test . After performing the Ruffier test, the HR of graduate students increased by 29% compared to rest, and after 1 minute of recovery, the increase in HR was 7%.

The dynamics of changes in heart rate in second-year full-time female master's students is presented in Table 8. As can be seen from the table below, after the functional test, the increase in heart rate is statistically significant (Table 8, Fig. 8). After one minute of recovery, the increase in heart rate was still significantly higher than at rest. Compared with third-year students, the recovery of female master's students after the Ruffier test is delayed, since even after one minute the heart rate does not reach the resting value . Such results can possibly be explained by a longer period of physical inactivity in female master's students, since the duration of their studies at the university is more than five years.

Table 8: *Heart rate indicators at rest and after performing the Ruffier test in 2nd year female master's students*

Functional state	Peace	Ruffier's test	Recovery, 1 minute
Heart rate, bpm	78.8±3.75	101.5±3.81***	83.9±0.40***

Ruffier index obtained by us when performing the Ruffier test on graduate students was 6.42 U (Table 9). Values above 6 to 10 indicate average performance of the cardiovascular system [8]. According to this source, the Ruffier index value from 6 to 7 occupies an intermediate position between good and average performance.

Thus , it can be concluded that the functional state of the cardiovascular system of second-year master's students is satisfactory.

Table 9: *Ruffier index after performing the Ruffier test*

Functional state	Ruffier's test
Index Ruthie	6.42±1.111

Evaluation of functional reserves of the cardiovascular system , health of young people studying is an urgent task. Most methods of evaluating functional reserves calculate some integral indices that are based on measurements of hemodynamic parameters at rest. At the same time, measurements at rest cannot fully reflect the state of human functional reserves and adaptive capabilities. To study the reserves of the cardiovascular system, motor tests are used. Motor muscle load causes hypoxia in the human body. Physical activity acts as a stress factor. In response to such an impact, human functional reserves are mobilized. As a rule, those well adapted to motor activity have good functional reserves of the body. Young people studying, due to the specifics of the educational process, are at risk, so assessing their health and functional reserves using functional motor tests is of practical importance.

1. Based on the nature of the change in blood pressure and heart rate in response to a motor test (Ruffier test), male and female students exhibit a normotonic type of response from the cardiovascular system;

2. The value of the Ruffier index indicates a satisfactory functional state of the cardiovascular system in male and female students;

3. According to the Robinson index, average (in girls) and good (in boys) functional capabilities of the cardiovascular system are noted;

According to the Kerdo index, sympathetic influences on the work of the heart at rest slightly prevailed in third-year female students ; parasympathetic influences prevailed in young men; an increase in the index was noted in both male and female students after the Ruffier test and an increase in the influence of the sympathetic link on the work of the heart;

5. The value of the adaptive potential of male and female students corresponds to the tension of the adaptation mechanisms, while the functional reserves are still preserved, although reduced;

6. The Ruffier index is an important indicator for assessing the physiological reserves of the cardiovascular system, as it characterizes its response to a motor test and adaptation to muscle work;

7. The cardiovascular system of the examined male and female students demonstrates satisfactory adaptation to short-term physical activity.

The interplay between climatic conditions and the adaptation of the cardiovascular system in students to physical activity is a critical area of study, especially in the context of sustainable development in education. Understanding how different climatic factors influence cardiovascular responses can lead to more effective training regimens, promote healthier lifestyles, and ensure the safety and well-being of students during physical activity.

1. Impact of Climate on Cardiovascular Responses: The body's cardiovascular system is designed to respond to the demands placed upon it during physical activity. However, external climatic conditions can significantly alter this response. For example, in hot and humid environments, the body may struggle to regulate its core temperature, leading to increased heart rates and potential heat-related illnesses. Conversely, in cold climates, blood vessels constrict to conserve heat, which may impair circulation and overall cardiovascular efficiency. Understanding these responses allows educators to tailor physical activities and training programs that account for local climate variations, ensuring that students can perform safely and effectively.

2. Adapting Training Regimens: Educators and coaches must adapt training regimens to the specific climatic conditions that students face. This includes modifying the timing of physical activities, choosing appropriate types of exercise, and ensuring adequate hydration and nutrition. For example, conducting outdoor training sessions during cooler parts of the day can mitigate heat stress, while incorporating warm-up routines that prepare the cardiovascular system for exertion in colder climates can enhance performance and reduce injury risks. By developing adaptive training strategies, educational institutions can improve cardiovascular health and performance among students while also instilling lifelong habits of safety and awareness regarding environmental conditions.

3. Importance of Education and Awareness: Promoting awareness of the effects of climate on health is essential for fostering resilience among students. Educational programs should emphasize not only the physical aspects of fitness but also the environmental context in which students operate. This can be achieved through integrated curricula that connect physical education with environmental science, encouraging students to understand how their surroundings impact their health. By educating students about the importance of adapting to climate conditions, we empower them to make informed decisions about their health and well-being.

4. Sustainable Development Goals: This discussion aligns with several Sustainable Development Goals (SDGs), particularly Goal 3 (Good Health and Well-Being) and Goal 4 (Quality Education). By focusing on the intersection of climate, health, and education, we can develop holistic approaches that promote student well-being while addressing environmental challenges. Schools can act as models for sustainable practices, promoting outdoor activities that are climate-sensitive and fostering a culture of health and fitness. Furthermore, students equipped with knowledge about the relationship between climate and health are more likely to engage in sustainable behaviors, contributing to community resilience and environmental stewardship.

5. Future Research Directions: Further research is needed to explore the long-term effects of climatic conditions on cardiovascular health in various populations. Longitudinal studies can provide valuable insights into how consistent exposure to specific climatic factors influences cardiovascular adaptation over time. Additionally, investigating the role of technology, such as wearable fitness trackers, in monitoring cardiovascular responses under varying climatic conditions can offer practical solutions for enhancing student health and performance.

In conclusion, the influence of climatic conditions on the adaptation of the cardiovascular system in students is a multifaceted issue that requires careful consideration in educational settings. By understanding these dynamics and implementing adaptive strategies, we can promote not only the physical health of students but also a broader commitment to sustainable development and environmental awareness.

ASSESSING THE VULNERABILITY OF BUILDINGS TO THE THREAT OF KARST SINKHOLES

Andrey Savinov, Gennadii Nigmetov, Temir Nigmetov
•
All-Russian Research Institute for Civil Defense and Emergency Situations, RUSSIA
savandr198@mail.ru

Abstract

Karst sinkholes pose a great danger to people and infrastructure in many countries, so effective methods for assessing karst hazard are needed. However, there are currently no modern regulatory documents and methods for assessing the danger of karst sinkholes. The article describes the methods and provides examples of the application of several methods for assessing karst hazard, tested in real conditions in the karst zone of the Bryansk region.

Keywords: sinkhole formation, karst collapse, electrical resistivity tomography, ground-penetrating radar, dynamic-geophysical method, dynamic sounding method

I. Introduction

Sinkholes pose a serious danger to people and infrastructure. They can form suddenly and without apparent cause, making them unpredictable and difficult to predict.

Sinkholes can occur as a result of various factors, such as underground waters washing away soil and rocks, or natural geological processes. They can also be caused by human activity, such as construction or mining, the use of rural baths and toilets that discharge waters that are chemically aggressive to limestone rocks into the ground.

Karst sinkholes can have serious consequences: destruction of buildings and structures, damage to communications, and loss of life. They can also cause environmental problems, such as groundwater pollution or changes to the landscape.

To prevent the danger of karst sinkholes, it is necessary to conduct research and monitor geological conditions in areas where there is a risk of their occurrence. It is also important to take precautions, when constructing and operating facilities in such areas.

When designing buildings and structures in areas prone to karst sinkholes, it is necessary to take into account the geological features of the area and use special construction technologies. This will reduce the likelihood of destruction of buildings and structures when a karst sinkhole occurs. It is also necessary to identify developing karst sinkholes in populated areas in advance. [1]

II. Study area and geological setting

Bryansk region is located in the central part of the East European Plain. The length from west to east is 270 km, from north to south - 190 km. In the southeast of Bryansk region there are settlements, which are characterized by karst sinkholes. Mainly, research on karst sinkholes was conducted in the city of Novozybkov and the village of Vyshkov.

In the walls of the failure, a section of soil and vegetation layer with a thickness of 0.2 meters and clay rocks with a visible thickness of 6-7 meters will be exposed.

Below the observed clay rocks lie waterlogged sands, under which there is a layer of chalk deposits with interlayers of Upper Cretaceous marls. Karst and suffusion phenomena are associated with the area of distribution of Upper Kaman chalk rocks and Paleogene terrigenous deposits in the southwestern regions of the Bryansk region. Karst processes are confined to zones of tectonic disturbances and the associated increased fracturing of the chalk strata.

Increased fracturing of the chalk rock mass, chemical dissolution of chalk rocks by aggressive waters of Quaternary deposits, mechanical leaching of chalk rocks and removal of clayey chalk in the discharge area lead to the formation of karst-suffusion cavities and subsequent failures.

Active use of agrochemicals, runoff from large livestock complexes, failure to comply with sanitary protection standards cause pollution of the aquifer complex with nitrates, nitrites, chlorides, sulfates. Groundwater is especially poorly protected, and therefore its use by household wells is not always environmentally safe.

III. Methods

There are several challenges associated with detecting emerging sinkholes in urban areas. First, settlements are usually located near water bodies; thus, there is an abundant supply of groundwater near the village. Second, with frequent anthropogenic activities affecting geophysical detection. Thirdly, power cables are buried under the subsurface around the village, resulting in an electric surface current that affects some processes [2].

Therefore, accurate detection results cannot be obtained using only a single geophysical method [2], [3]. Therefore, we integrated multiple geophysical approaches, namely, dynamic-geophysical method (DGM), Ground-penetrating radar (GPR), dynamic sounding method (DSM), to improve the accuracy of detecting sinkholes.

Ground-penetrating radar GPR

The objective of the GPR survey was to determine the condition of the soil mass in the failure zone along longitudinal and transverse profiles. And also, to study the school territory for the presence of forming failures. The profiles are located both along and across the failure of the soil relative to the direction of the street. The purpose of the GPR studies was to identify zones of possible manifestation of karst and suffusion processes on radargrams [2].

GPR is based on the study of the field of high-frequency electromagnetic waves (frequencies from the first tens of MHz to the first units of GHz are used). The method is based on the difference in rock permittivity. The emitted pulse, propagating in the examined environment or object, is reflected from the boundaries at which the electrical properties change - electrical conductivity and permittivity. The reflected signal is received by the receiving antenna, amplified, converted into digital form and stored. As a result, from an ordered set of reflected signals, a section of the examined environment is formed, perpendicular to the plane of the georadar antennas, called the GPR profile [4].

The main quantities measured in GPR are the travel time of an electromagnetic wave from the source to the reflecting boundary and back to the receiver, as well as the amplitude of this reflection. Such interfaces in the studied environments are, for example, the contact between dry and water-saturated soils (groundwater level), contacts between rocks of different lithological composition, between rock and the material of an artificial structure, between frozen and thawed soils, between bedrock and loose rocks.

Dynamic sounding method DSM

For DSM, small-sized and powerful geological equipment will be appropriate. This method is used where clayey and sandy soils of any type of occurrence are studied. DSM specializes in obtaining complete and very accurate data on sandy and clayey soils.

DSM stages:

- Geological equipment is installed on a prepared site, appropriate equipment is selected so that its parameters meet the tasks and operating conditions;
- Then, using a hammer, the probe is driven into the ground;
- After a series of blows, the depth of the probe in the ground is measured;

- Sounding is completed when the probe reaches the design depth, or when, after a series of blows, the probe is immersed in the ground no more than 3-4 cm.

Dynamic geophysical method (DGM)

DGM is based on the assessment of the integral rigidity of a structure based on characteristic features and criteria that appear when processing the dynamic parameters of the "soil-structure" system.[5]

One of the features characterizing rigidity is the period or frequency of natural oscillations of the structure. Since the period of natural oscillations of the structural system of the structure is directly proportional to its mass and inversely proportional to its rigidity, then by measuring the frequency or period of natural oscillations, one can evaluate the rigidity of the structure. To evaluate the standard value of the period of natural oscillations of the structure, expressions obtained from the solution of differential equations describing its oscillation are used [6], [7]:

$$T=k\times\sqrt{(m/EJ)} \quad (1)$$

where

m – linear weight of the system, kg/m;

EJ – the rigidity of the system as the product of the modulus of elasticity and the moment of inertia, H×м2;

k – coefficient taking into account the structural design of the building.

IV. Results

As an example of the methods' operation, the data measured in the area of the school in the village of Vyshkov in the Bryansk region were taken. Since this zone was the most socially important, the largest number of measurements were made there by various methods. The main measurement methods were: dynamic probing, GPR and DGM.

GPR

In the surveyed area 12 GPR profiles were made. One of them is shown in Fig. 1.

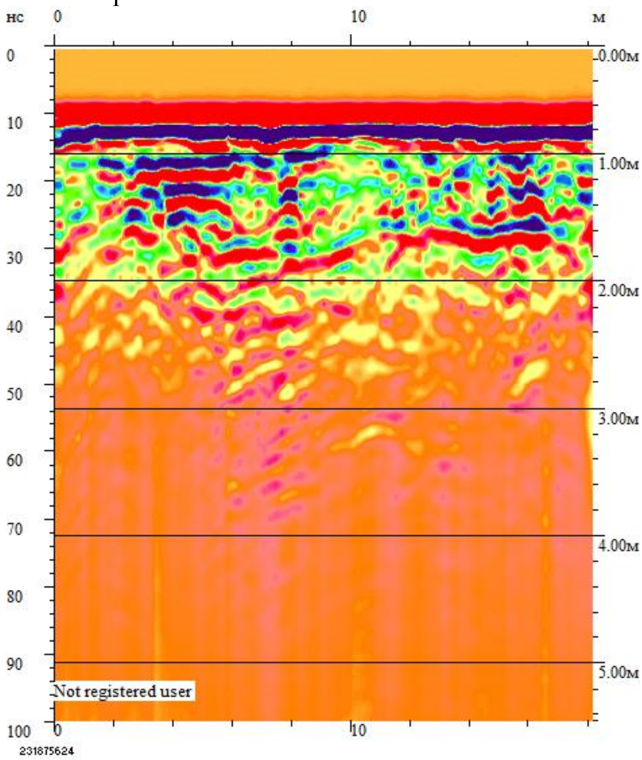

Figure 1: *GPR profile at the site of a possible karst failure*

On all georadar profiles the device does not give data below 3-4 meters, which indicates strong waterlogging of the soil. With the help of GPR, small anomalies were noticed and 2 zones of possible formation of a karst failure were identified.

DSM

DSM confirmed the high-water content of the soils. (Fig. 2) In addition, in places of possible karst failures, the dynamic probe easily entered the soil massif and showed weak soil resistance.

Figure 2: *Waterlogged soils on the extracted probe*

DGM

The dynamic parameters of the soil-building system include the frequencies of natural vibrations and the damping decrements along the X, Y, Z axes.

The frequencies characterize the rigidity of the system, the damping decrements show how the vibrations of the system are damped.

When assessing the soil mass, the researchers were guided by the following points:

- each type of soil of the same thickness is characterized by a certain level of the average weighted period (Taw);
- the values of Taw vary depending on the thickness and type of soil;
- the presence of a loose soil layer (arable land, etc.) causes the presence of high values of Taw in the immediate vicinity of the source of soil vibrations;
- at a distance of about 30-40 m from the source, the values of Taw approach the values of the prevailing period of vibrations (Tpr) for a layer thickness of 8-10 m ($Tpr=4H/v_s$);
- with distance for soils of great thickness (H>10 m) at a distance of more than 40 m, an abrupt increase in Taw is observed, approaching the corresponding Tpr; moreover, for soils (thickness H≈8-10 m) the increase in Taw with a distance of more than 30-40 m is small.

Thus, the study of average-weighted periods allows us to study both the physical and mechanical properties of soils and their resonance properties, determined by the equality of average-weighted and prevailing periods of oscillations.

Another indicator for searching for failures was the characteristic pronounced pulsation of the soil massif. (Fig. 3)

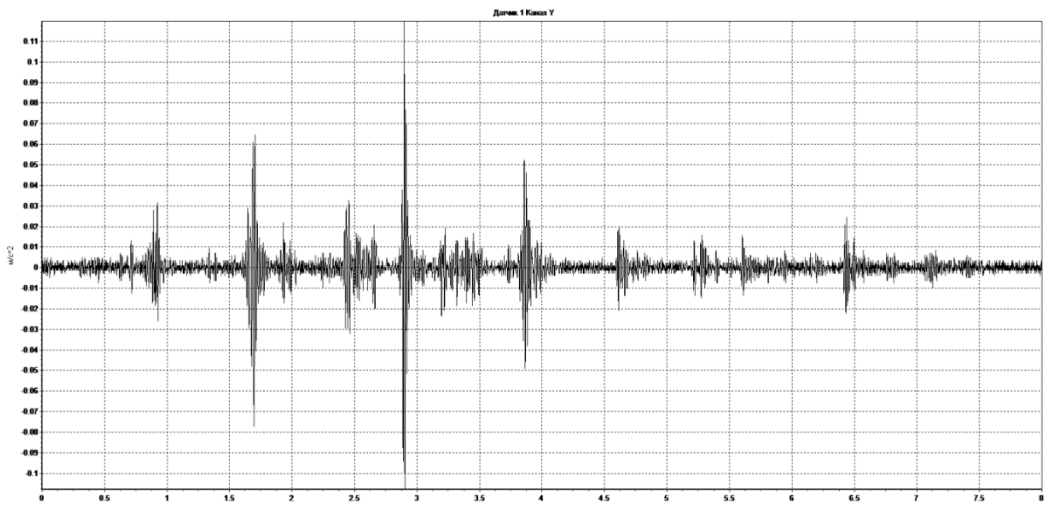

Figure 3: *Soil mass vibrations with pronounced pulsation*

Based on dynamic geophysical measurements (Table 1) and expert analysis, a map was constructed with zones of increased karst hazard. (Fig. 4)

Table 1: *The degree of karst hazard assessed using dynamic geophysical measurements*

Point	Fx, Hz	Fy, Hz	Fz, Hz	Degree of karst danger (in points from up to 10)
	100	105	100	9
2	30-100	3,75;60	41,648	6
3	38	39,2	0,15	8,5
4	5,25	4,35	5,2	9
5	34,6	94,8	0,15	8,6

22	10-25	10-25	10-25	4
23	9,95	12,8	12,8	3

Figure 4: *High karst hazard zones (red) at the school construction site, obtained from the results of processing DGM*

According to the dynamic geophysical soil tests in 2023, there is a threat of karst hazard at the building construction site (Fig. 4). The vibration spectra in the low-frequency region are equal to (2.3-7.25) Hz and correspond to waterlogged soils.

V. Discussion

During the surveys conducted in the karst hazardous area, a huge amount of data was collected. The data collection included various types of work, such as dynamic probing, ground penetrating radar and dynamic geophysical methods.

The collected data helped to better understand the characteristics of karst phenomena in this area and to develop recommendations for the safe use of the territory. They can also be used to predict possible changes in the karst system and to develop measures to prevent dangerous situations.

The main reason for the occurrence of karst sinkholes in the Bryansk region is the shallow depth of the chalk layer and its high-water saturation. And as a result of human activity such as the use of private rural baths and toilets, as the active use of agrochemicals, runoff from large livestock complexes, non-compliance with sanitary protection standards, pollution of the aquifer complex with nitrates, nitrites, chlorides, sulfates is caused. Groundwater is especially poorly protected.

In the course of the study of karst sinkholes by the three methods described above, DGM was found to be the most suitable. With the help of this method, anomalous areas of possible formation of karst sinkholes were identified.

The results of this method were subsequently confirmed by DSM. This method confirms places where the soil is greatly weakened, but this method is too point-based and labor-intensive. To assess karst hazard zones even in a small area, it is necessary to make a huge number of measurements with driving a titanium rod into the soil at each point. As an independent method, the DSM is not applicable separately from others.

GPR showed the most mediocre results. This method shows itself excellently for assessing soils to a depth of 10 m, but if the soils are not water-saturated. In this situation, the signal was jammed at depths of 3-4 m and the specialists were practically not able to see the anomalous zones.

Abstract

In order to ensure trouble-free operation of offshore oil production and transportation facilities, it is necessary to consider seismic hazard in their design. As part of this work, seismic hazard calculations were performed for the Zhenis oil and gas field facilities located in the Kazakhstan sector of the Middle Caspian. According to this project, the initial seismicity and seismic microzoning were clarified, i.e., accounting for real soil conditions made by different methods. Calculations showed that the intensity of seismic shocks in the Zhenis field can be 8.31 points on the MSK-64 scale, which corresponds of acceleration of a sea bottom ground of 0.253 g.

Keywords: Caspian Sea, seismic hazard, offshore oil and gas facilities, seismic microzoning

I. Introduction

The assessment of the seismic hazard of the water areas is carried out to ensure the seismic resistance of marine structures. However, research in this area makes it possible to solve other tasks that are not directly related to the problems of seismic safety of field development facilities. In particular, information about the maximum seismic impacts in a particular region makes it possible to solve not only the traditional tasks of engineering seismology and earthquake-resistant construction, but also to find application in the study of global climate change.

There are many hypotheses that differently explain the global climate change on our planet. Among them, as it seems to the authors of this article, a new theory of academician L. I. Lobkovsky about the influence of strong subduction earthquakes on the Earth's climate [24]. The author shows that strong earthquakes (M=8-9) result in tectonic waves in the lithosphere, which contribute to the emergence in the sedimentary cover of additional stresses commensurate with the stresses created by tidal deformation waves, and which are accompanied by the dissociation of metastable gas hydrates and the release of large volumes of methane into the atmosphere, which in turn leads to rapid global warming and global sea level rise. In this regard, it seems relevant to assess the level of seismic hazard in other areas, in particular, in the Caspian Sea, which contains gas hydrates in its sedimentary apron [3] and located at a relatively short distance from the Alpine-Himalayan collision zone.

Modern normative maps of general seismic zoning OSR-2015 A, B, C do not contain information on the intensity of seismic shaking (score) in the water areas of inland and marginal seas of Russia. Such information in integer MSK-64 score values is contained in the OSR-97 maps, which are not up to date.

Seismological monitoring using temporary and permanent networks of autonomous (ground and bottom) seismic stations is carried out to refine seismotectonic models of the studied region and detailed seismic zoning (DSZ) [10-13]. Description of operating systems of bottom seismological monitoring is given in works [14,18,21,26]. The results of using monitoring data for constructing seismotectonic models are given in [15,16,22,23,26]. If instrumental observations are not carried out, it is necessary to carry out work to clarify the initial seismicity (CIS) by computational methods, using both seismotectonic models already developed for the area under study and refined models. In our case (the Middle Caspian region), an example of such a model is given in [27], and a refined model in [19].

The purpose of seismic microzoning (SMR) is to quantify the influence of local conditions (soil composition, relief features, presence of active faults, etc.) on the seismicity of the site, indicating the change in the intensity of shaking in points according to GOST 6249-52 (Russian Standard) or in acceleration values in units of gravity (g).

II. Clarification of initial seismicity

The initial seismic impacts for the offshore oil and gas field Zhenis (Kazakhstan sector of the Middle Caspian Sea) were calculated by the method of probabilistic seismic hazard analysis (PSHA) [9] using the modified program SEISRISK III [6].

The input data for the PSHA are models of possible earthquake source zones (PES zones), earthquake recurrence models for these zones, and suitable attenuation models for the computed ground motion parameters (accelerations or response spectra). These models are prepared based on the analysis of available geological-geophysical and seismological data for the study area.

In this work we used the lineament-domain-focal (LDF) model of seismic hazard zones of the Middle Caspian Sea, which is the basis of seismic hazard calculations under the Global Seismic Hazard Assessment Program project [27], refined in accordance with [19] and shown in Fig. 1.

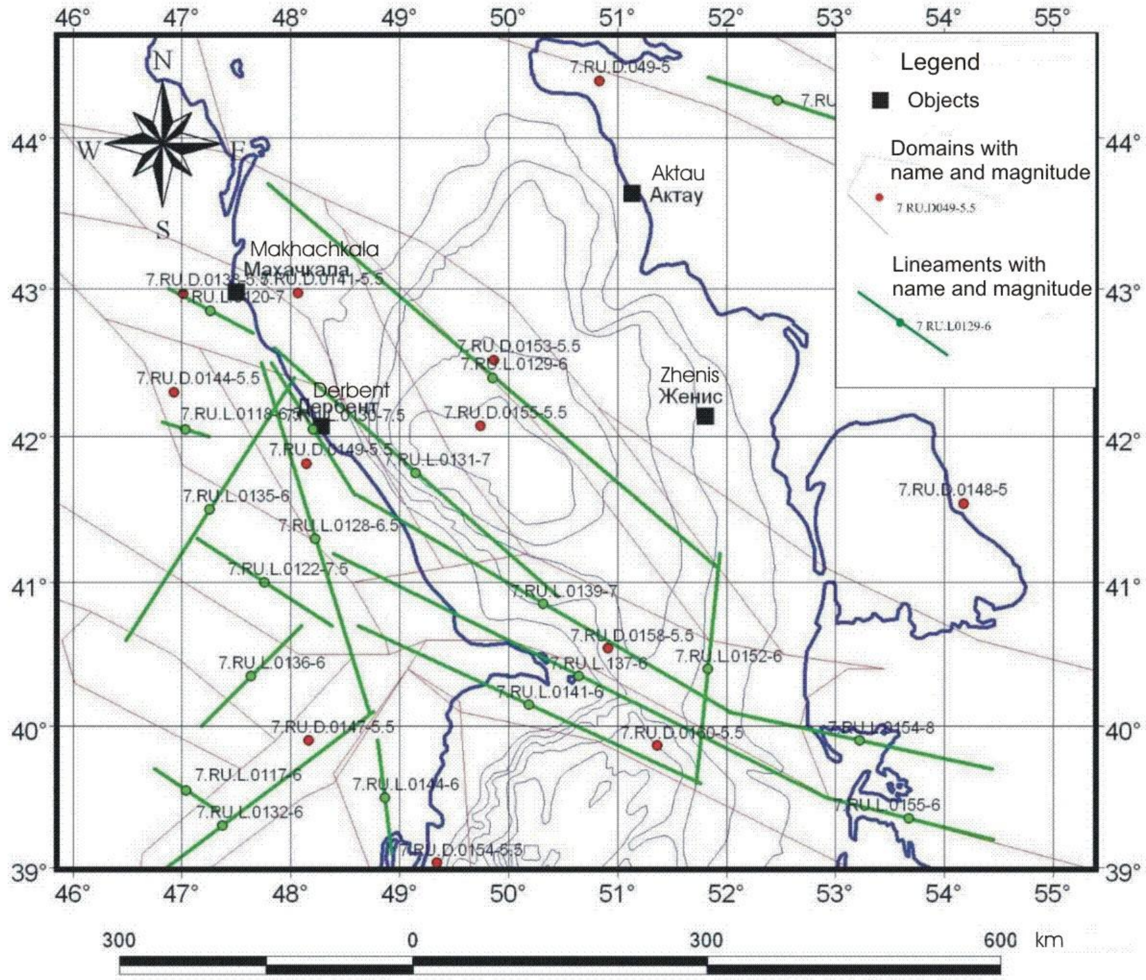

Figure 1: *Lineament-domain-focal model of seismic hazardous zones of the Middle Caspian Sea, which is the basis for seismic hazard calculations under the Global Seismic Hazard Assessment Program Project [27], refined in accordance with [19]*

The recurrence curves for this model are shown in Fig. 2 (lineaments). They are nonlinear relationships between the decimal logarithms of the number of earthquakes occurring over a period of one year within the specified PES zone (lineament or domain) and the magnitude of the earthquake. The plots are constructed using the database of the Global Seismic Hazard Assessment Program Project [27] with refinements in accordance with [11,12].

In this work, we used the models of attenuation of SA (T, 5%) acceleration response spectra for the simplest oscillatory systems modeling the response of individual elements of complex structures to seismic effects - linear oscillators with 5% attenuation. For each spectral period T of ground oscillations, a separate dependence of the response spectrum on the magnitude M and the distance R to the observation point is required. Values of M: from 4.0 to 8.0 in steps of 0.5; values of R: from 1 km to 1024 km to the observation point. These models were developed from databases of strong ground motions recorded from earthquakes with foci in the Earth's crust (H<=35 km) occurring in tectonically and, therefore, seismically active regions of the globe. Among the initial data were records of earthquakes in Turkey, Iran, Caucasus (Spitak), Central Asia. The Caspian Sea region also belongs to tectonically active regions of the globe, and the main hazardous events here are earthquakes with foci in the Earth's crust. Therefore, the applicability of these attenuation models in this case can be considered justified. The used models [1,2,4, 7] are shown in Fig. 3.

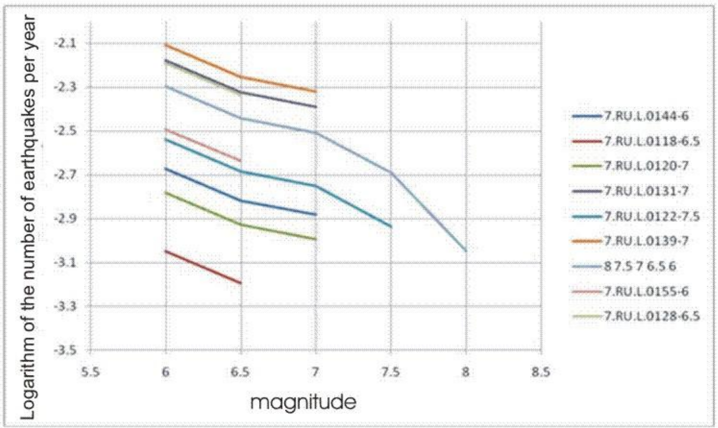

Figure 2: *Earthquake recurrence curves for earthquake dangerouse lineaments of the Middle Caspian Sea and adjacent land areas*

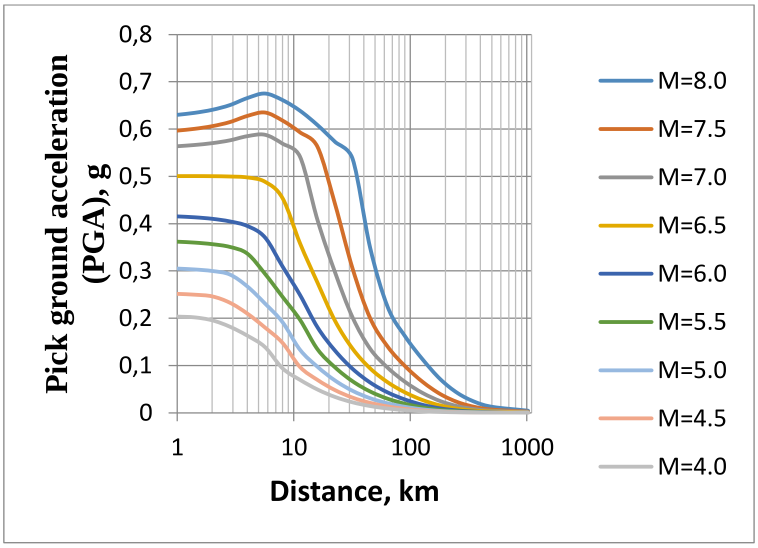

Figure 3: *Models of peak ground acceleration attenuation (PGA, g) as a function of distance*

The performed calculations have shown that for average soils of the Zhenis site for the design-basis earthquake (DBE, recurrence period 5000 years) seismic shaking intensity is 0.2 g in terms of PGA (peak horizontal ground acceleration) or 8 points in terms of seismic shaking intensity in MSK-64 scale points, which practically coincides with the data of OSR-97C map.

For the operating-basis earthquake (OBE, 500-year recurrence period), the seismic shaking intensity is 0.075 g in terms of PGA (peak horizontal ground accelerations) or 6.55 in terms of seismic shaking intensity in MSK-64 scale points, which is 0.45 points below the value shown on the OSR-97A map.

Various methods exist for modeling the nature of expected ground motions at the site under investigation. One of the most useful methods for design purposes is the method of calculating synthetic (artificial) accelerograms, velocigrams and seismograms whose response spectrum coincides with the design one.

In this work, we used the method proposed in [25] to calculate the ensemble of the most probable expected accelerograms for the area of the Zhenis well site. The method is based on the summation of a Fourier series consisting of sinusoidal oscillations with amplitudes varying according to the lognormal law, both in time and frequency, and with random phases uniformly distributed in the interval $[0, 2\pi]$.

Fig. 4 shows the response spectrum with 5% attenuation calculated with the SEISRISK III program for a recurrence period of 5000 years assuming that the Zhenis site is composed of soils of II category according to SNiP II-7-81* (Russian Standard), as well as the average statistical response spectrum constructed from an ensemble of 10 synthetic accelerograms. This ensemble of accelerograms (Fig. 5) corresponds to the design-basis earthquake (DBE) - close seismic events with magnitudes MLH=5.5 occurring at a distance of 5 km from the site. Both spectra are close to each other. The difference does not exceed 10%.

The performed calculations have shown that for average soils of Zhenis site for the design-basis earthquake (DBE, recurrence period 5000 years) seismic shaking intensity is 0.2 g in terms of PGA (peak horizontal ground acceleration) or 8 points in terms of seismic shaking intensity in MSK-64 scale points, which practically coincides with the data of OSR-97C map. For the operating-basis earthquake (OBE, recurrence period 500 years) intensity of seismic shaking makes 0.075 g in terms of PGA (peak horizontal ground acceleration) or 6.55 points in terms of intensity of seismic shaking in MSK-64 scale points, which is 0.45 points lower than the value specified in OSR-97A map. The SEISRISK III-calculated spectra of initial seismic shaking for medium soils with 5% attenuation (red curve in Figure 4) and synthetic accelerograms modeling the initial seismic shaking were further used for SMZ purposes.

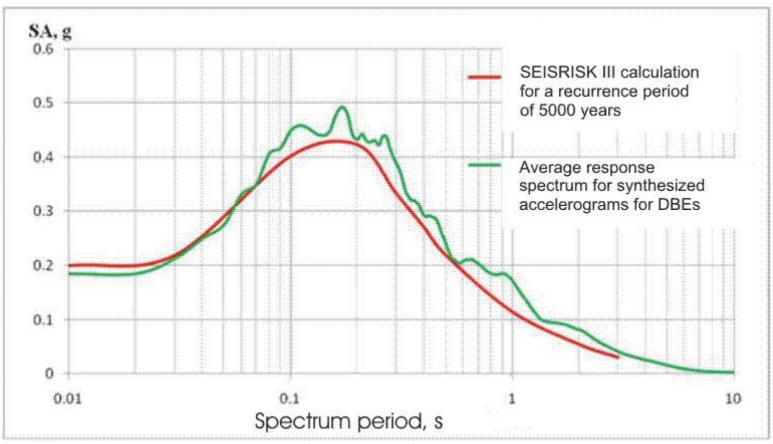

Figure 4: *Reaction spectrum with 5% attenuation calculated using the SEISRISK III program for the recurrence period of 5000 years and the average statistical reaction spectrum constructed from an ensemble of 10 synthetic accelerograms of the corresponding DBEs*

III. Seismic microzonation

For the purposes of seismic microzonation of the Zhenis site seafloor ground models were developed using high-resolution seismic data from the HR MRW CDP seismic survey and drilling data (Fig. 6).

The HR MRW CDP seismic record obtained in the study area is divided into two parts corresponding to the Cenozoic and Mesozoic stages of sedimentation.

The upper part of the section (interval - 50÷1000 ms, the most interesting for SMZ purposes), corresponding to the Cenozoic sediments (Quaternary, Pliocene-Quaternary, Miocene and Maikop), is characterized by parallel-layered, rather high-frequency record with numerous extended reflecting horizons (Fig. 6).

Within the Quaternary seismic complex, there is an intense reflecting horizon A, corresponding to the roof of the Apsheron sediments (the crimson-colored line in the section shown in Fig. 6.1). This seismic horizon can be traced throughout the Caspian megabasin. In the central part of the megabasin it lies conformally with the overlying and underlying boundaries, in the lateral parts it is distinguished as a shear surface with elements of roof adjoining the lower boundaries. The horizon is traced over the whole area in the record interval of 163-172 msec.

The bottom of Quaternary sediments is marked at the level of 186÷197 msec. The B horizon corresponding to this boundary is traced on the temporary sections (light green color line in Fig. 6).

Several types of seismic geologic sections were developed.

● Cross-sections to a depth of 35 m from the seafloor, constructed from longitudinal seismic wave velocity data and recurrence relations linking longitudinal and transverse seismic wave velocities in the upper layer of bottom sediments. These are the Mudrock Line equation [7], and the Boore relations [8], which relate seismic wave velocities in sediments and rock densities.

● Cross-sections to a depth of 35 meters from the seabed, based on seismic and drilling data. The latter were used for reconstruction of the upper (15 m) part of the section.

● Cross-sections constructed to a depth of 140 m for a deep well using drilling data for the upper part (74 m) and seismic data to a depth of 140 m (Fig. 7).

SMZ calculations to take into account the influence of bottom soils on seismic parameters were performed using two different methods: the seismic rigidity method and the calculation method using the NERA program [5].

The NERA calculation for the section developed to a depth of 140 m at the location of the deep borehole gave A_{max}=0.215 g or 8.08 points of MSK-64 scale. This calculation for this section using the NERA program was performed in accordance with the recommendations of STO 95 12022-2017 (Departmental Standards of Rosatom State Corporation). For the section to a depth of 35 m, these values were higher: A_{max} = 0.253 g and 8.31 points in seismic shaking intensity values on the MSK-64 scale.

The calculations of grade increment by the method of seismic rigidity were performed using two relations.

1. S.V. Medvedev's formula:

$$\Delta I = 1.67\log(R_{ref}/R_i), \quad (1)$$

where R_{ref} is the seismic rigidity of the reference soil, R_i is the seismic rigidity of the investigated soil. ($R=V_s \times \varrho$, V_s – shear wave velocity, ϱ – density of the rock or ground). It was used to process the section constructed to a depth of 35 m.

2. Formula from the current SMZ norms SP 283.1325800.2016 (Russian Standard):

$$\Delta I = 2.5\log(bR_{ref}/(R_i+R_{ref})) \quad (2)$$

where R_{ref} is the seismic rigidity of the reference soil (V_s>800 m/s, ϱ>2.5 g/cm^3), R_i is the seismic rigidity of the investigated soil, b is the maximum dynamic coefficient.

Figure 5: *Examples of the ensemble of synthesized accelerograms for the design-basis earthquake (DBE) MLH=5.5, R=5 km*

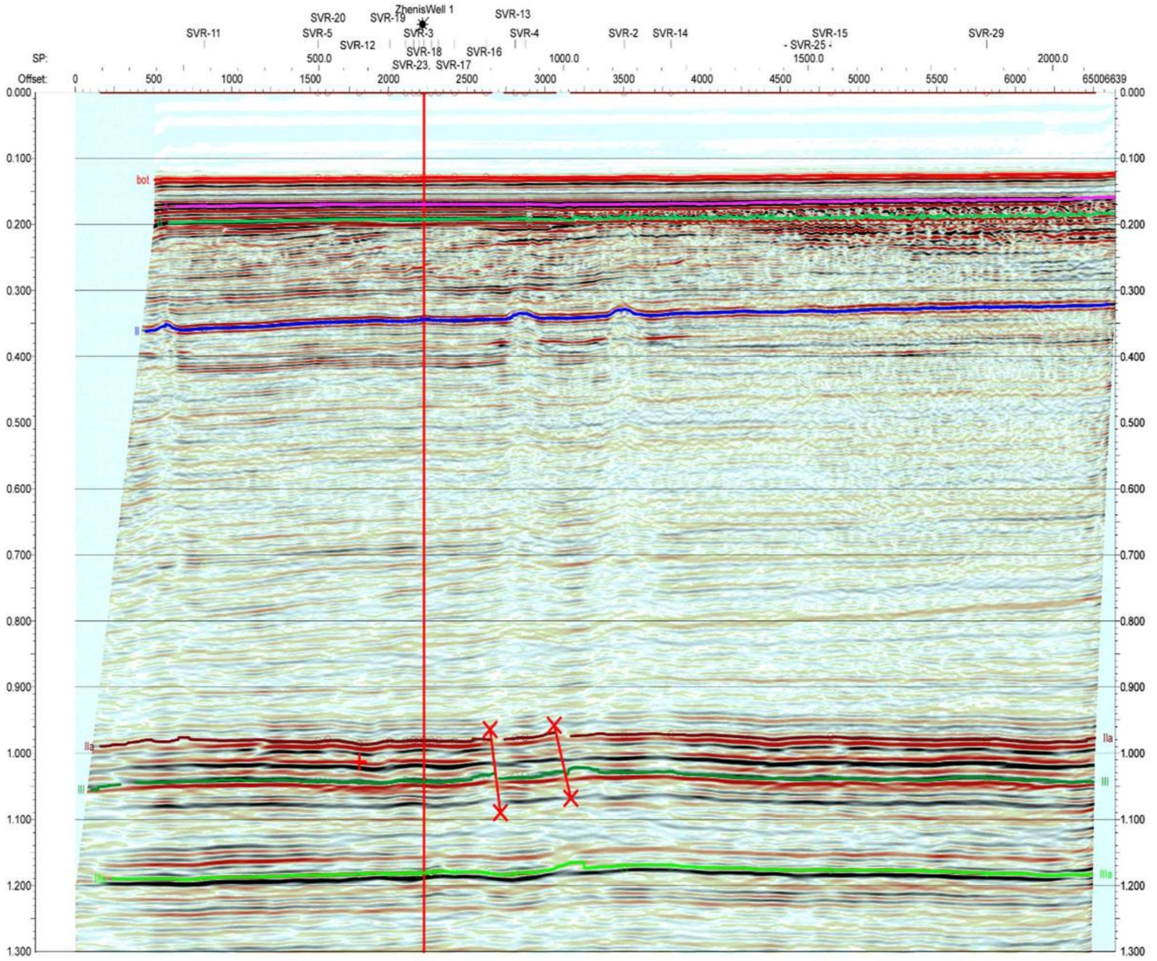

Figure 6: *Time section along the profile passing through the well at the Zhenis site*

Formula (2) was used to calculate the grade increment for the deep cross-section (140 m) in accordance with the guidelines of SP 283.1325800.2016 (Russian Standard). The use of these two formulas yielded the following values of the pointness at the bottom soil surface: for the 35 m cross-section A_{max} = 0.236g, I = 8.208; for the 140 m cross-section and the formula from SP 283.1325800.2016 A_{max} = 0.275 g, I = 8.430. The discrepancies in the results of using different calculation methods can be explained by the fact that all the above approaches to calculating seismic impact parameters to account for ground conditions have been developed for land. They need to be verified by in situ measurements on the seafloor using bottom seismographs and records of remote and local earthquakes. Such studies are very rare, but their necessity is evident for both SMZ and DSZ purposes. Examples of seismological monitoring and DSZ at sea are given in [10-15, 18, 21-23].

A total of 18 such cross-sections were constructed, which were further used for calculations using the NERA program to determine seismic parameters on the seafloor surface in the southwestern part of the Zhenis site.

The distribution of the calculated seismic parameters over the study area is shown in Fig. 8 and 9 for the design-basis earthquake (DBE).

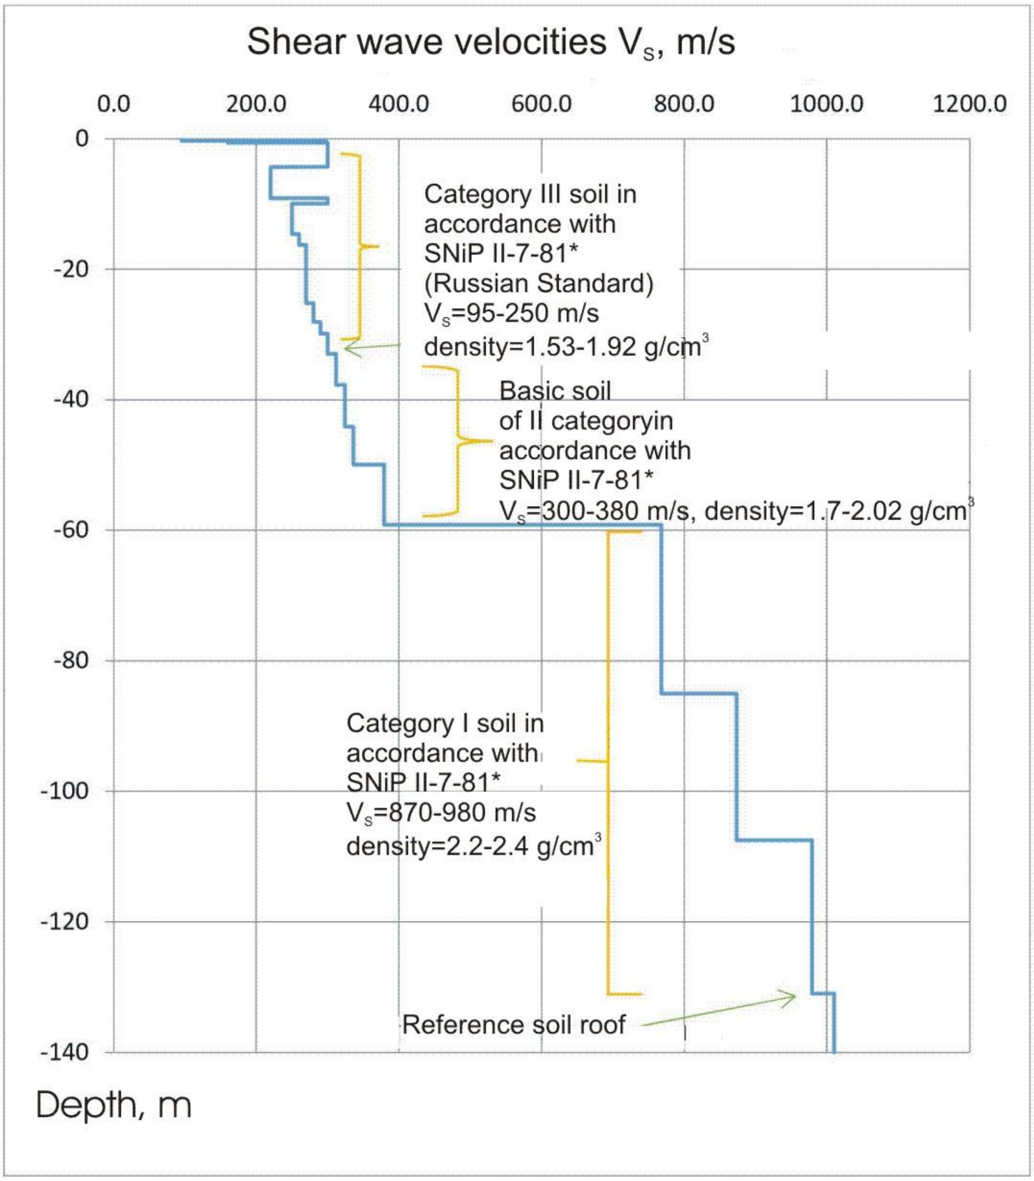

Figure 7: *Seismogeologic cross-section for the well obtained from drilling data to a depth of 74 m and seismic data from CDP reflection waves to a depth of 140 m*

Thus, the results of seismic zoning of the Zhenis site, obtained by two different methods and different input parameters: the method of seismic rigidity and the computational method according to the NERA program with cross-sections constructed solely on the basis of seismic data and cross-sections constructed with the involvement of geotechnical data, showed insignificant differences in the values of seismic effects on the ground surface.

In addition, it is necessary to point out the following circumstance: from Fig. 10 it can be seen that the spectrum on the surface of bottom sediments, calculated without taking into account real soil conditions, significantly differs in shape from the spectrum calculated taking into account geotechnical data. Although the amplitudes of maximum accelerations in both cases practically coincide. Perhaps the spectrum acquires a resonant shape due to the presence in the section of a layer of very soft clays up to 9 m thick, which is detected by drilling and not found by seismic methods. Or it is necessary to take into account the properties of bottom sediments according to the methods described in the works [17, 20].

VI. Conclusion

The performed calculations have shown that for average soils of the Zhenis site for the DBE seismic shaking intensity is 0.2 g in terms of PGA (peak horizontal ground acceleration) or 8 points in terms of seismic shaking intensity in MSK-64 scale points, which practically coincides with the data of OSR-97C map.

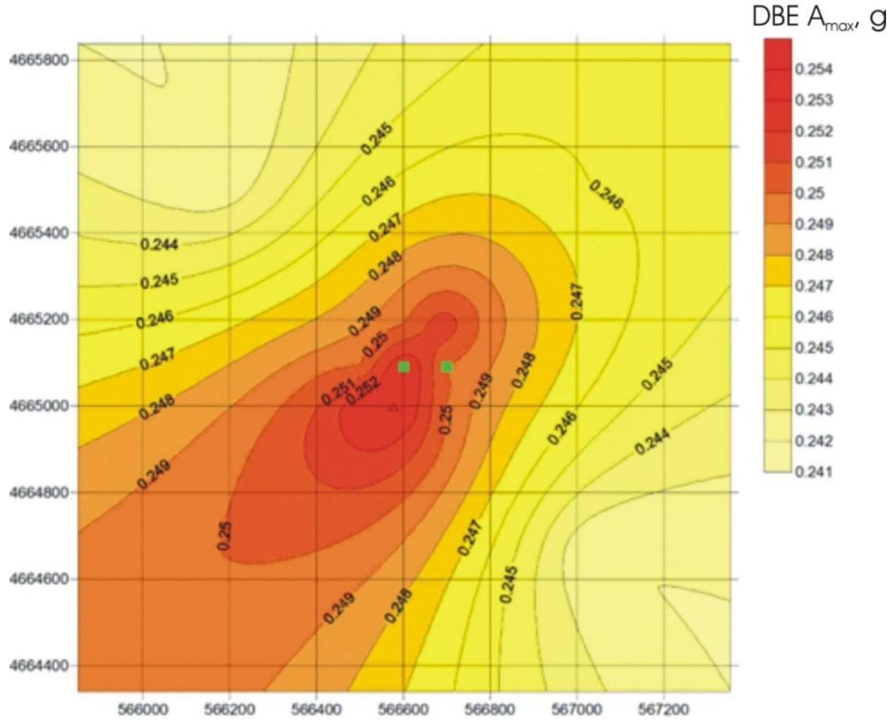

Figure 8: *Distribution of the amplitude of the maximum acceleration of the bottom soil A_{max} in fractions g in the southwestern part of the Zhenis site. Well locations are shown in green boxes*

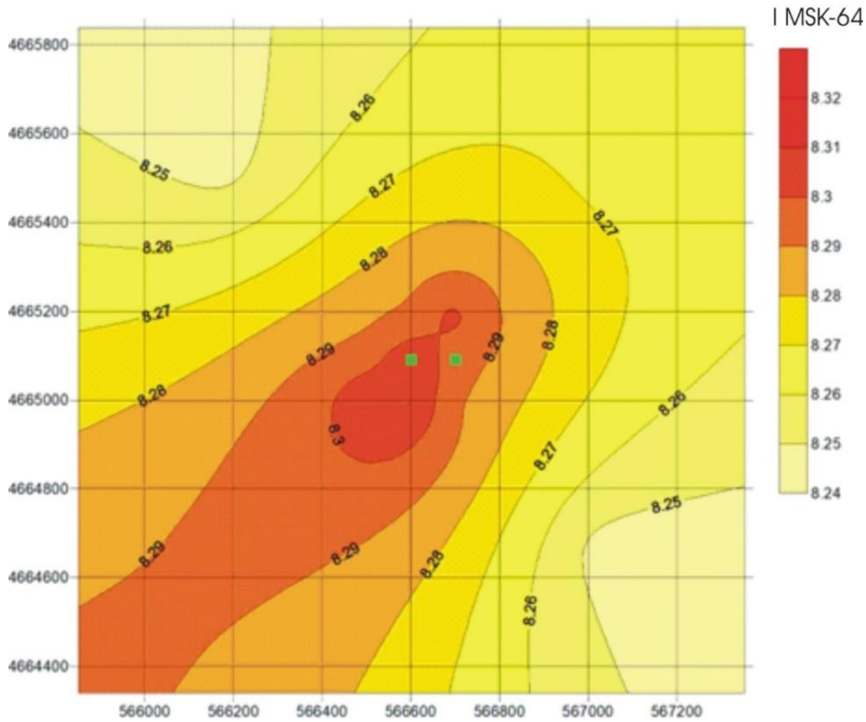

Figure 9: *Distribution of seismic impact intensity on the bottom soil surface in MSK-64 scale points in the southwestern part of Zhenis site for SSE. Well positions are shown in green squares*

The SMZ calculations to take into account the influence of bottom soils on seismic parameters were performed using two different methods: the method of seismic rigidity and the calculation method using the NERA program [4]. For the first method, seismogeological sections constructed to a depth of 35 m using seismic data were used.

For the calculation method, geotechnical cross-sections were also used. All calculated seismic parameters, taking into account the influence of bottom soil, were plotted on the SMZ maps.

A NERA calculation was also performed for a cross-section developed to a depth of 140 m at the BHV well location. This calculation showed that the amplitudes of the maximum accelerations A_{max} are smaller than A_{max} calculated from the section to a depth of 35 m: 0.215 g and 0.253 g for the maximum design earthquake. These values are 8.08 and 8.31 points in the values of seismic shaking intensity on the MSK-64 scale. All this is true for the DBE.

This is not the case with the of operating-basis earthquake OBE. The A_{max} for the OBE plotted on a cross-section to a depth of 140 m is 0.1 g or 7 MSK-64. For another cross-section plotted to a depth of 35 m, the A_{max} is 0.073 g or 6.69 MSK-64.

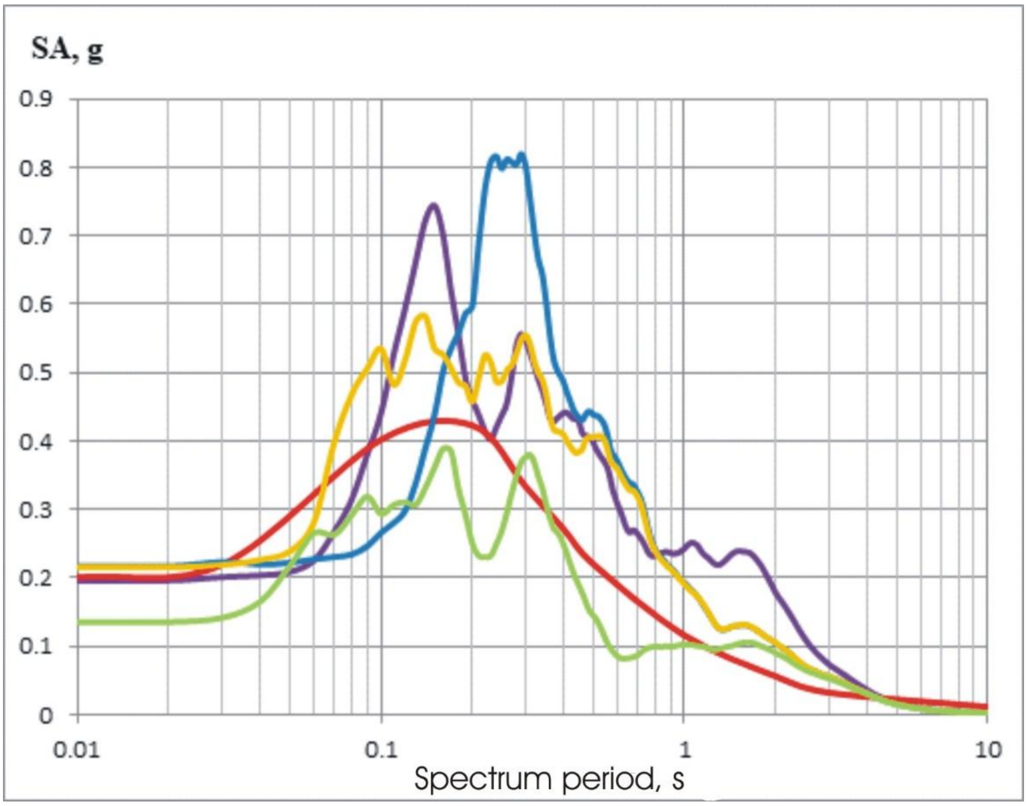

Figure 10*: Seismic response spectra with 5% attenuation for the Zhenis site for DBE. Red curve - initial seismic impacts, green curve - seismic response spectrum on the roof of Apsheron sediments (roof of basic soils); yellow curve - spectrum on the surface of the bottom soil of the well (74 m), calculated on the basis of the cross-section constructed without taking into account geotechnical data at the depth of 35 meters; blue curve - the same one for the section built with geotechnical data, purple curve - the same one for the section with geotechnical data built at a depth of 140 m to the reference soil roof*

This effect can be explained by the fact that for a OBE, seismic impacts are less intense than in the case of DBE. Therefore, the seismic signal is less affected by the non-linear properties of the ground, which weaken its amplitude.

For the OBE for the BHV borehole on the bottom soil surface of the Zhenis site, the maximum acceleration value A_{max}= 0.1 g or IMSK=7 MSK, as more conservative values, should be assumed for the OBE.

The results of using the seismic rigidity method were very close to the results obtained by the computational method.

Methods for assessing the potential for bottom liquefaction show a non-zero probability of this occurring. However, the burial of the anchors in the case of a semi-submersible drilling rig, or of the platform supports

in the case of a jack-up drilling rig, reduces this probability to zero. To the southeast of the Apsheron sill, a lineament structure can be traced, where earthquakes with M = 8 can occur, which, according to L. I. Lobkovsky's ideas, generates decomposition of gas hydrates.

Funding

The study was carried out within state task no. FMWE-2024-0018 (data acquisition) and was supported by the Russian Science Foundation, grant no. 23-17-00125 (development of data interpretation methods).

THE INFLUENCE OF NATURAL AND CLIMATIC CONDITIONS ON THE INTEGRATION PROCESS OF DEPORTED PEOPLES IN SPECIAL SETTLEMENTS

Sapiyat Tsutsulaeva

Kadyrov Chechen State University, RUSSIA
sapiyat_univ@mail.ru

Abstract

This paper delves into the complex role that natural and climatic conditions played in the integration process of deported peoples who were forcibly relocated to special settlements, particularly during the Soviet era. The research investigates how the extreme environments—ranging from harsh winters and scorching summers to remote and isolated regions—impacted not only the physical survival of the deportees but also their social, economic, and cultural adaptation in these new and often hostile locations. The analysis draws on historical data to examine how different environmental factors influenced the daily lives, labor conditions, and community structures of the deported populations. In many cases, these peoples were relocated to areas with severe weather conditions, poor infrastructure, and limited access to basic resources, which created significant barriers to their integration into the local economy and society. The climatic extremes often forced the deportees to adapt quickly to new agricultural practices, unfamiliar landscapes, and arduous working conditions, while also challenging their physical endurance and mental resilience. Furthermore, the paper explores how these environmental hardships affected the relationships between deportees and the local populations, as well as their interactions with Soviet authorities. The study also looks into the long-term effects of these forced migrations on the cultural and social identity of the deported peoples, highlighting the enduring legacy of such relocations in shaping the historical memory of these communities.

I. Introduction

The forced relocation of entire populations to special settlements during the Soviet era represents one of the most significant social and demographic transformations of the 20th century. From the 1930s through the 1950s, millions of people, often from ethnic minority groups, were deported to remote and underdeveloped regions of the Soviet Union. These resettlements were a result of political and security considerations, with the Soviet government aiming to control potentially “disloyal” populations by moving them far from their native lands. However, beyond the political motives, these deported peoples faced immense challenges due to the natural and climatic conditions of the areas they were forced to inhabit.

This study focuses on the impact of those environmental conditions—particularly the harsh climates, geographic isolation, and scarcity of natural resources—on the integration process of these deported peoples. Integration, in this context, refers not only to the economic incorporation of the deportees into local labor systems but also their social and cultural adaptation to their new surroundings. For many, the abrupt shift from familiar environments to regions with extreme cold, desert heat, or dense forests created profound obstacles to survival and social cohesion.

The conditions in which these people found themselves often determined the pace and extent of their adaptation. In Siberia, for example, where winters could be long and harsh, deportees had to endure subzero temperatures while attempting to cultivate new lands or work in labor camps with limited resources. In contrast, those relocated to Central Asia faced a different set of environmental challenges, including extreme heat and droughts that affected agricultural productivity and basic living conditions. The diversity of these climatic challenges created varied experiences of integration, with some communities managing to establish new livelihoods while others struggled under the weight of environmental and economic pressures.

In this context, the objective of the research is to analyze how these natural and climatic conditions influenced the integration of deported peoples into special settlements. By exploring the intersection of environmental hardship, labor demands, and social adaptation, this paper seeks to shed light on how geography and climate affected not only the immediate survival of these populations but also their long-term socio-economic and cultural integration into Soviet society.

This investigation into the role of climate and geography will help to enrich our understanding of the broader historical experience of forced migration and resettlement. While much of the existing scholarship on deportations has focused on the political and economic aspects, the environmental factors remain underexplored. By focusing on the natural conditions that deported peoples faced, this study aims to fill this gap, offering a nuanced perspective on the integration processes within special settlements.

II. Methods

This study employs a multidisciplinary approach to analyze the influence of natural and climatic conditions on the integration process of deported peoples in special settlements. The methods used include a combination of historical analysis, geographical assessment, and qualitative case studies, drawing on both primary and secondary sources. The research is designed to provide a comprehensive understanding of how environmental factors shaped the experiences of these deported populations during their resettlement and adaptation.

1. **Historical Document Analysis**:

The primary method involves the analysis of archival records, government reports, and personal testimonies from deported individuals. Soviet-era documents, including official resettlement plans, labor assignments, and population censuses, provide crucial insights into the logistical and administrative aspects of the deportations. These records are cross-referenced with memoirs, letters, and oral histories of deportees to capture the lived experiences of those affected. By comparing official Soviet reports with personal narratives, the research aims to uncover the discrepancies between state policies and the realities faced by the deported peoples.

2. **Geographical and Climatic Data Assessment**:

A significant aspect of the research focuses on the geographical and climatic conditions of the regions where deportees were sent. This involves the use of historical climate data and geographic mapping to analyze the specific environmental challenges faced in different regions, such as Siberia, Kazakhstan, and the Russian Far East. Factors such as average temperatures, precipitation levels, and soil quality are examined to assess how they impacted agricultural productivity, labor requirements, and living conditions in the special settlements.

By mapping deportation locations and overlaying climatic data, the study seeks to correlate environmental conditions with integration outcomes. For example, settlements in extremely cold regions are compared with those in arid or semi-arid areas to identify patterns in survival rates, labor output, and community development.

3. **Case Study Analysis**:

The research also employs a case study approach to provide detailed accounts of specific deported communities and their adaptation processes. These case studies focus on deported groups such as Chechens, Crimean Tatars, and ethnic Germans, who were relocated to different regions under varying climatic conditions. Each case study looks at factors such as employment in local industries, agricultural success, mortality rates, and social cohesion to understand how natural environments influenced integration.

By using a comparative case study method, the research highlights how some groups managed to adapt more successfully than others, depending on the environmental conditions they encountered. These case studies are drawn from a variety of sources, including regional archives, local histories, and ethnographic studies.

4. **Qualitative Interviews and Oral Histories**:

In addition to archival research, the study incorporates qualitative interviews and oral histories where available. Interviews with descendants of deportees, as well as existing oral history projects, provide personal insights into the challenges faced by these populations and how they perceived the impact of climate on their daily lives. This qualitative data helps to capture the emotional and psychological aspects of integration that are not always reflected in official documents.

5. **Thematic Analysis**:

The data collected from archival research, climate analysis, case studies, and interviews are subjected to thematic analysis. Key themes such as "adaptation to harsh climates," "resource scarcity," "labor struggles," and "social cohesion under environmental stress" are identified and analyzed to explore the broader patterns of integration. This thematic approach helps to link the specific experiences of different deported groups with the overarching influence of environmental conditions.

6. **Comparative Analysis**:

Finally, a comparative analysis is conducted between different groups of deported peoples and the various regions to which they were relocated. This allows for the identification of factors that either facilitated or hindered the integration process across different natural and climatic contexts. Variables such as the type of labor, proximity to local populations, government support, and climatic severity are considered in comparing the experiences of deported communities.

Through this combination of methods, the study aims to offer a comprehensive and nuanced understanding of the role that natural and climatic conditions played in shaping the integration of deported peoples in special settlements.

III. Results

Soviet and Russian historian N. F. Bugai explains the deportations of individual ethnic groups by the fact that the Soviet authorities feared their possible betrayal. This assumption became the basis for preventive accusations and forced expulsion of entire peoples. The reasons for deportations also included: collaboration with the fascists (treason), belonging to a nation or religion with which the war was waged, which could lead to support for the enemy due to ethnocultural proximity. The strategic goals of these deportations included: 1) establishing fear in order to control the country; 2) undermining the internal unity of peoples and promoting ethnic assimilation; 3) shifting the blame for the political and economic mistakes of the regime onto the repressed peoples; 4) increasing the population in sparsely populated regions of Siberia, Kazakhstan and Central Asia; 5) providing labor resources for the backward regions of the USSR. Thus, according to the decree of the Presidium of the Supreme Soviet of the USSR of October 12, 1943 and the resolution of the Council of People's Commissars of October 14, 1943, the Karachays were subject to deportation to the Kazakh and Kirghiz SSRs. On November 2, 1943, 69,207 people were deported from the Karachay Autonomous Region, as well as 424 Karachays found in neighboring regions. The bulk of the deportees were placed in the South Kazakhstan Region (25,212 people), the Dzhambul Region (20,285 people) and Kirghizia (22,900 people), and small groups were sent to Tajikistan, the Irkutsk Region and the Far East. They were later joined by 2,500 demobilized Red Army soldiers. In the early years, the local population, under the influence of propaganda, was suspicious of the settlers from the North Caucasus. However, the similarity of the languages of the Karachays and Balkars with the languages of the Kyrgyz, Kazakhs and Uzbeks contributed to the establishment of trusting relationships between the special settlers and the local population.

IV. Discussion

Despite being deported under extremely difficult conditions, Chechens and other ethnic groups played a significant role in the development of Kazakhstan's economy. They were employed across various industries, including mining, agriculture, and construction, often under grueling circumstances. For example, in 1945, Chechen workers on the Balqash mine exceeded production quotas by 200-300%. This indicates that, although initially inexperienced in certain industries, they adapted quickly and contributed to crucial sectors like coal mining and industrial construction. Their labor not only helped meet the economic demands of the war and post-war periods but also facilitated the modernization of Kazakhstan's infrastructure.

Discussion Point: How did the contribution of Chechen laborers affect the broader narrative of forced resettlement in the Soviet Union? Did their participation in nation-building challenge the negative stereotypes associated with them?

2. Adaptation and Professional Development

The process of adapting to new professions was not without challenges. Many settlers initially struggled due to their lack of experience in industrial work and poor Russian language skills. However, through bunched work teams and training programs, they eventually gained the skills necessary to meet and exceed production standards. For instance, the introduction of brigade methods of teaching proved to be an effective approach for accelerating skill acquisition, as evidenced by the remarkable productivity of individual workers like the drill operator Mezhidov and others.

Discussion Point: What does this tell us about the adaptability and resilience of deported populations under extreme pressure? How important were education and skills development in their successful integration?

3. Harsh Living and Working Conditions

The text underscores the inhumane living conditions experienced by the special settlers upon their arrival. The forced relocations were conducted under severe circumstances, leading to overcrowding, lack of food and clothing, and high mortality rates. Despite these obstacles, the settlers managed to not only survive but also thrive in the industrial workforce. This raises the question of the role that labor played in their survival and integration into new environments. Labor became a means of both survival and resistance to their marginalized status.

Discussion Point: How did the harsh living conditions affect the settlers' psychological and physical well-being? In what ways did work serve as a mechanism for survival and eventual social inclusion?

4. Political and Social Context of Deportation

The deportation of Chechens, along with other ethnic groups, was part of a larger Soviet policy that sought to control perceived threats to state security during World War II. The settlers were initially stigmatized as "traitor peoples," which justified their harsh treatment and relocation. However, as the text highlights, by the 1950s, there was a shift in attitudes, with authorities beginning to publicly acknowledge and reward the contributions of these workers.

Discussion Point: How did the shift in political attitudes towards special settlers reflect broader changes in Soviet society during the post-war period? How did their labor contributions challenge or reinforce Soviet narratives about loyalty and productivity?

5. Historical Memory and Legacy

The narrative around Chechen special settlers, and deported peoples more broadly, has a complex legacy. On one hand, their forced relocation was a significant human rights violation, but on the other hand, their labor contributed to the economic development of Kazakhstan and other regions. This duality poses difficult questions about how such historical experiences are remembered and interpreted.

Discussion Point: How should the legacy of forced resettlement and labor be remembered? Should the focus be on the hardship endured, the contributions made, or both? What are the implications for contemporary discussions about historical memory and reconciliation?

In sum, the experience of Chechen special settlers in Kazakhstan highlights themes of resilience, forced adaptation, economic contribution, and shifting political perceptions in Soviet history. These themes invite a broader conversation about the complex dynamics between state policy, labor, and the lived experiences of marginalized populations.

On December 28, 1943, the deportation of Kalmyks to the Krasnoyarsk and Altai Territories, Omsk and Novosibirsk Regions began. One of the largest groups deported from the North Caucasus were the Chechens. On February 23, 1944, about 400,000 Chechens and more than 90,000 Ingush were forcibly resettled. According to the report of the Deputy Chief of the 3rd Directorate of the NKGB of the USSR D. V. Arkadyev from March 11, 1944, out of 180 trains with deportees, 171 arrived at their destination, and 9 trains remained en route. By March 11, 1944, 468,583 people had arrived at the resettlement sites: 24,281 in Jalal-Abad Region, 16,565 in Dzhambul Region, 29,089 in Alma-Ata Region, 34,167 in East Kazakhstan Region, 20,808 in South Kazakhstan Region, 39,542 in North Kazakhstan Region, 20,309 in Aktobe Region, 31,236 in Semipalatinsk Region, 41,230 in Pavlodar Region, and 37,938 in Karaganda Region. They were later joined by thousands of Chechens and Ingush who had been discharged from the Red Army after February 1944. More than 60,000 people were resettled in Kazakhstan.

On March 8, 1944, about 38,000 Balkars were deported, and on May 18, 1944, more than 180,000 Crimean Tatars were expelled from Crimea. Professor V. B. Ubushaev from the Kalmyk State University rightly emphasizes that "the deportations of peoples were carried out spontaneously and had no legal basis. For each people subject to punishment, L. Beria opened a special case with incriminating documents, which he then presented to I. Stalin. These materials were selected tendentiously and did not stand up to serious verification." In the areas where special settlers were resettled, the NKVD organized special commandant's offices, and the status of the deportees was determined by the instructions of the NKVD and the NKGB of the USSR, decrees of the State Defense Committee, as well as the regulation of January 8, 1945 "On the special commandant's office." The deportees could participate in elections to the Supreme Soviet of the USSR and were gradually drawn into public life, but their rights were limited in wartime conditions. Once a month, they were required to report to the commandant's office, signing a special journal. The special settlers retained the status of citizens of the USSR, but did not have the right to leave their designated places of residence, which had a negative impact on social life based on family support. Many families were separated, and the Ministry of Internal Affairs carried out work to find and reunite them. The authorities of the Union republics and local executive committees were engaged in the economic arrangement of the settlers, based on the decisions of the Council of People's Commissars of the USSR. Usually, preparations for the placement of deportees began a month or a month and a half before their eviction, providing for a set of measures to arrange for the resettled families. However, in practice, the implementation of these measures encountered difficulties due to a lack of material and economic resources, harsh climatic conditions and sometimes the negligence of local authorities. This led to an increase in morbidity and mortality among the settlers. For example, in Kazakhstan in 1944, 32,502 people died, and in 1945, 32,111 people. The highest mortality was recorded in the second half of 1944 and the first half of 1945, which coincided with the period of acclimatization, as well as food difficulties and a shortage of clothing and footwear.

Special settlers worked actively in all sectors of the national economy of Kazakhstan. Documents from regional archives testify to the significant contribution of Chechens to this activity. By the fall of 1944, 2,158 Chechen special settlers worked in enterprises and collective farms in Leninogorsk. At first, their productivity was low due to lack of experience, weak discipline and difficult living conditions. Additional difficulties were created by the language barrier, but over time, the special settlers mastered professions and increased their labor efficiency. The use of team training methods helped speed up this process, and by August 1944, 415 people fulfilled and 382 exceeded labor standards. In 1946, 1,044 people worked in the mines of Leninogorsk, including 332 Chechens, many of whom significantly exceeded plans. From the first days of their stay in the Karaganda region, able-bodied men were involved in production. In 1945, 628 Chechens worked at the Balkhash mine, of which 426 regularly exceeded the plan by 200-300%. New professions for special settlers were actively mastered: in 1947, 75 tractor drivers and 7 drivers were trained, 472 people were trained at FZO enterprises, and 355 people mastered new specialties. By January 1, 1948, 10,393 people worked at 75 industrial enterprises in the Karaganda region, 2,414 in Temirtau, and 3,122 in Balkhash.

By 1952, 15,114 special settlers from the North Caucasus worked at enterprises and construction sites in the region, including Chechens employed in the coal industry and construction. They participated in coal mining, construction of industrial and residential facilities, and railway repair. The reports noted that most of the special settlers were conscientious about their work, and from the mid-1950s their successes were openly encouraged.

Thus, the deported peoples, including the Chechens, despite the difficult conditions of resettlement and life, made a significant contribution to the development of the country's economy, refuting the myth of "traitor peoples."

Abstract

In recent years, there has been significant focus on utilizing production and household waste to create polymer composites. These composites can be employed either independently or in a modified form, and can also serve as additives. The aim of our study was to develop composite materials using epoxy resin and household rubber waste and to evaluate their properties. We tested various aspects, including water absorption, flexural strength, and adhesion.

Keywords: adhesive, rubber, composite, ecology, epoxy resin

I. Introduction

Today, no country is free from issues related to waste management. This is especially true in large nations with high populations, where both domestic and industrial waste can reach enormous volumes. Landfills consume vast areas of land and contribute to soil, air, and water pollution, which often leads to various diseases and epidemics. Thus, a comprehensive approach to waste management is essential to address these challenges. The primary objective is to minimize both domestic and industrial waste. People often dispose of garbage in landfills, rivers, or valleys, making waste a significant source of environmental pollution. Typically, waste is "disposed of" by being dumped in landfills, where it is then crushed and covered with layers of soil. It may seem as though the waste has "disappeared" once buried, but this is not the case. Waste is just hidden underground and remains a significant environmental concern. Decomposing waste generates harmful gases that are released into the atmosphere, and rainwater infiltrates the waste, becoming contaminated with its harmful substances. If a landfill lacks a system to collect and treat this contaminated runoff, the polluted water can eventually mix with groundwater or rivers, leading to severe pollution. Additionally, some waste decomposes very slowly, taking decades to break down while continuously polluting air and water. On a positive note, silicon-containing compounds can enhance the properties of composite materials. Epoxy resins, known for their excellent physical, mechanical, and technological characteristics, are widely utilized in creating various materials, including heat-sensitive adhesives and composites designed for extreme conditions [1-10].

Our objective is to develop new construction materials using recycled rubber waste, epoxy resin, and ethyl silicate. By incorporating rubber waste, we not only recycle household waste but also contribute to environmental improvement. These materials stand out from other options due to their cost-effectiveness, user-friendly technology, and resistance to microorganisms. Additionally, they meet all contemporary standards for building materials.

II. Experimental part

Processing. In a specialized mixer, we combine epoxy resin, ethyl silicate, and rubber waste in varying proportions. After adding a stabilizer, we thoroughly mix the components. The mixture is then poured into specific molds and left to set overnight. The following day, we remove the material from the molds, conduct a thermostatic treatment, and proceed with testing.

Fourier transform infrared spectra were determined with a Varian 660-IR FT-IR Spectrometer. The KBr pellets of samples were prepared by mixing (1.5–2.0) mg of samples, finely grounded, with 200 mg KBr (FTIR grade) in a vibratory ball mixer for 20 s.

Microstructure of the samples was studied by NMM-800RF/TRF type of optical microscope SEM and EDS observations were conducted. Measurements were performed under a microscope - Tescan Vega 3, LMU, LaB 6 cathode. Maximum accelerating voltage was 30 kV, resolution 2.0 nm. The microscope was also equipped with an energy dispersive spectrometer of X-ray-induced electron beam specimens (EDS, Oxford Systems). EDS was used to analyze the sample compositions.

Impact viscosity determination, also called *shock viscosity* determination, is a technique applied to soft solids and is essentially a drop impact test. The drop height h is the vertical distance between the upper surface of the tested material (h_1) and the bottom surface of the drop hammer at the end of the impact event (h_2). With the sample mass m and the acceleration g, the work performed by the falling hammer is mg ($h_1 – h_2$), anormalized with respect to the horizontal cross-section of the specimen.

Vicat softening depth consists in the determination of the depth of the indentation with respect to the top surface caused by a flat ended indenter with the cross-section of 1 mm^2. The load applied is 10 or 50 N and the cross-section of the indenter end is circular. The term *Vicat hardness* is also in use – really confusing since larger values correspond to lower hardness.

Water absorption is determined simply as the percentage weight change of the sample after submersion in water. We have performed such measurements after 3 hours and 24 hours exposition to water

III. Results and discussions

Composites were produced using epoxy resin, rubber waste, and ethyl silicate, and were subjected to testing. We determined the strength limit of the composites and examined how it depended on both the content of rubber waste and its modification with ethyl silicate. Based on the curves shown in Fig. 1, we observed an increase in the strength limit of the epoxy resin-based composites with varying concentrations of rubber waste. The three curves presented in the figure exhibit both qualitative and quantitative differences. The first curve represents the strength limit as it relates to the amount of unmodified rubber waste. This curve displays a broad peak, illustrating the well-known relationship between composite strength and filler concentration. The mechanical strength of composites containing unmodified rubber waste peaks at relatively low concentrations (10-20%). In contrast, rubber waste modified with ethyl silicate (3-5%) significantly enhances the mechanical strength of the composite, shifting the maximum strength to higher concentrations of rubber waste (as shown in curves 2 and 3). This finding is practically important: the more mineral fillers a polymer composite includes, the lower its intrinsic cost. Curve 3 shows an interesting trend: a single peak is observed at relatively low filler concentrations, while at higher concentrations, the curve becomes disrupted. This disruption occurs because achieving high filler content in composites is technically challenging, primarily due to difficulties in uniformly distributing the filler within the polymer matrix.

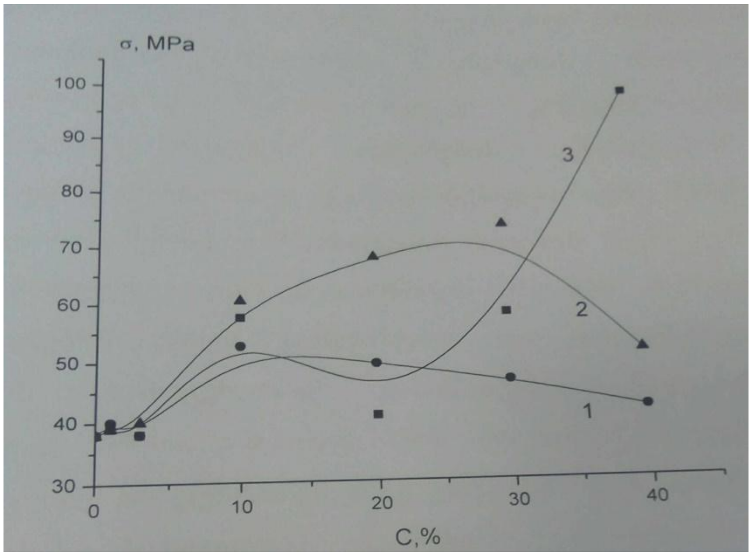

Figure 1: *Dependence of the strength limit of ED-20 + rubber residue composites on the content of rubber residue for*

The curves indicate that finely dispersed rubber tire powder significantly enhances both the mass density and strength of the composites compared to those with the same concentrations of unmodified rubber. The addition of ethyl silicate, a modifier, greatly impacts the mechanical properties of the composites. The siloxane compound on the rubber grain surfaces activates them, and during heat treatment, ethyl silicate likely forms bonds with the macromolecules of the epoxy resin. It fills the gaps between polymer blocks and creates a "buffer" zone between the rubber and the polymer. This interaction between the epoxy resin and ethyl silicate results in the formation of additional physical, Van der Waals, sorption, and chemical bonds, which collectively enhance the mechanical strength of the composites compared to their unmodified counterparts. Epoxy resin composites filled with modified rubber powder demonstrate better compatibility compared to those with unmodified rubber, as evidenced by superior mechanical strength indicators. The mechanical stresses in the composite, whether from compressive or tensile forces, are effectively absorbed by the relatively soft siloxane phase. This phase helps to limit and contain the development of microdefects within the carbon chain matrix, thus reducing the overall thickness of the composite. These structural improvements are also reflected in the thermo-mechanical properties of the materials. Composites with rubber residues modified with ethyl silicate exhibit a higher and more consistent softening temperature compared to those with unmodified rubber residues. This behavior correlates well with the mechanical strength values, suggesting that the modified filler has a stronger interaction with the polymer molecules through the modifier than the unmodified filler.

The enhanced compatibility of rubber residues in the carbon chain matrix of the composite, facilitated by ethyl silicate, is evident from the water absorption properties. Table 1 reveals that increasing the filler concentration generally leads to larger microstructures and the formation of interconnected or isolated microvoids, resulting in higher water absorption rates. However, composites with rubber residues modified by ethyl silicate exhibit significantly lower water absorption rates compared to those with unmodified rubber residues. This reduction can be attributed to the well-known hydrophobic nature of siloxane compounds, which greatly decreases water absorption in composites with modified fillers.

Table 1: *Dependence of Composite Water Absorption on Ethyl Silicate Content*

Rubber Residue Content	Ethyl Silicate Content	% of water absorption after 3 hours	% of water absorption after 24 hours	Density
10	0	0	0	1.1252
20	0	0.08	0.12	1.2332
40	0	0.14	0.36	1.2546
10	3	0.053	0.108	1.2198
10	5	0.032	0.100	1.2341
20	3	0.062	0.116	1.2455
30	5	0.072	0.266	1.2678

It has been established that ethyl silicate enhances the hydrophobicity of the composite by a factor of four at a 10% concentration, while also increasing both the softening temperature and mechanical strength. The modification of rubber residues with 3% and 5% ethyl silicate leads to a significant increase in the composite's mechanical strength up to a certain concentration of rubber residues. The strength dependence curve for these modified composites shows a peak much higher than that of composites filled with unmodified rubber waste. Specifically, composites with 5% ethyl silicate-modified rubber waste exhibit substantially greater maximum strength compared to those with 3% ethyl silicate-modified rubber waste. All composites incorporating ethyl silicate-treated rubber waste demonstrate notable hydrophobic properties.

Abstract

Landslides are considered as a complex process in which anthropogenic activity plays an important role. The purpose of this work is to describe the cause-and-effect relationships in the system "anthropogenic activity - landslides" using the example of mountainous regions of the Chechen Republic. The article is based on field studies and materials from the interpretation of high-resolution space images, which made it possible to identify about 1800 landslides in the territory of the Chechen Republic. They were characterized in terms of landscape position (coordinates, height, exposure, slope, vegetation composing rocks) and involvement in economic activity (forestry, pastures, agriculture, settlements, etc.). The results of the work made it possible to assess the mutual influence of landslides on settlement, on the one hand, and land use (in particular, road construction, irrigation, etc.) on the nature of landslides. A detailed analysis of the obtained database made it possible to identify 356 landslides that somehow fall within the analysis field of the "landslide - person" system. The analysis of the relationships was carried out based on the superposition of various layers of the created geoinformation system. Anthropogenic activity was assessed in three aspects: 1) spatial proximity of landslides and economic objects; 2) intensity and type of economic activity influencing landslide manifestations; 3) dynamics of land use over time, in particular, a sharp change from one type of use to another.

Keywords: landscapes, slope exposure, human impact, landslides

I. Introduction

Mountains and mountain ranges are complex and multifaceted geosocio-ecological systems and play a crucial role in biodiversity, hydrological cycles and human society. Mountainous areas face numerous challenges, including climate change, land use change, which lead to slope instability, erosion, mudflows, landslides. Landslides are caused by geological, meteorological and human factors, which vary not only depending on the natural environment, but also depending on the socio-territorial context. In recent years, the impact of landslides on the economy and settlement has become more serious due to the overlap of various interacting factors. Therefore, mountainous regions around the world are faced with an increase in poorly predictable catastrophic events, cascading effects and an increase in natural disasters. Landslide phenomena often form areas that can be considered as specific disaster zones - risk landscapes. Risk landscapes are complex, heterogeneous and uncertain territories, which confirms the need to consider the relationship between nature and society at different levels of time and space. The mountainous territories of the Chechen Republic have long been well developed [1]. There is a well-developed settlement system here, which underwent significant changes in the 20th century, many settlements were abandoned, the population migrated to the foothills and to the plain. On the other hand, the developed territories in the mountains were affected by slope processes, primarily landslides. Traditional forms of life activity allowed for the formation of relatively long-term symbioses of the environment and settlement with a high degree of adaptation. However, the development of new technologies for the construction of residential buildings, roads, communications and, in general, land use, led to the disruption of traditional adaptation mechanisms and the intensification of landslides.

II. Methods

The article is based on field studies and high-resolution satellite imagery interpretation materials, which allowed us to identify about 1,800 landslides in the Chechen Republic. Profiles were built for key areas, which included not only the landslide body itself, but also the surrounding landscape, including land use and settlement. This allowed us to assess the mutual influence of landslides on settlement, on the one hand, and land use (in particular, road construction, irrigation, etc.) on the nature of landslides. A detailed analysis of the resulting database allowed us to identify 356 landslides that, in one way or another, fall within the scope of the analysis of the "landslide - person" system [2]. The remaining landslides were classified as conditionally natural, since the main factors influencing their dynamics were natural processes: river erosion, natural instability of slopes, earthquakes, etc. All 356 landslides were characterized in terms of geographic location (coordinates, height, exposure, slope, vegetation, landscapes that make up the rocks), as well as in terms of inclusion in economic activity (forest management, pastures, agriculture, settlements, etc.). The analysis of the relationships was facilitated by the presence of various layers of the created geographic information system. The use of layer overlay operations and loading of images from different years made it possible to assess the dynamics of the relationship between economic activity and landslides in different periods of development: in Soviet times (intensive land use), in the 1990s (weakening of economic activity, migrations caused by military actions), in the 2000s and to the present (construction of roads, communications, creation of new settlements in safe places, migrations to the city, etc.). The study of changes in land use was also supported by field surveys of key areas, landscape mapping and profiling [3].

Landscape management within the high-altitude zonal landscape-landslide complexes has undergone significant changes over the past 80 years. The highland landscapes, densely populated before the deportation of the Chechens in 1944, were used as a basis for life – for arable land, hayfields and grazing. The destruction of the settlement system and the deportation of mountain dwellers to the plain led to the expansion of use in the form of distant-pasture livestock farming, mainly as pastures for sheep driven in the summer from collective farms in the foothills and plains. The settlement of abandoned villages was prohibited in Soviet times. In the late 1980s, individual families began to gradually reclaim their ancestral lands. The process stopped during the military actions, but then resumed in the 2000s. However, individual entrepreneurs gradually began to drive small herds (mainly bulls) to summer pastures. With the construction of roads, the development process accelerated. In recent years, high-mountain areas, in particular the basin with Lake Galanchozh in the center, have become a weekend tourism destination. However, the laid dirt roads significantly reduced the stability of the slopes and began to serve as sources for the development of landslide processes. In the foothill-low-mountain zone, where the densely populated areas of the Chechen Plain and the Black Forest meet, mountain forests have long been used for firewood, and individual farms developed sections of clearings in the mountain forests. However, this process was slowed down due to the lack of areas suitable for farming. In Soviet times, forest management began to be regulated. The return of the Chechens in the late 1950s and the restoration of villages led to a change in the settlement structure, an increase in the number of livestock and an increase in the need for firewood [4]. During the military actions of the 1990s, the surrounding landscapes suffered greatly. The restoration in the post-war period was accompanied by the installation of gas supply, which had a positive effect on the forest cover. In addition, the basis of the population's life has changed, which is now largely associated with work in cities. This has led to a decrease in the livestock population, stall keeping and driving to high-mountain areas are used. All this gave the mountain forests a chance to recover.

The development of the oil industry played a major role in the use of the landscapes of the front ranges. The network of wells and infrastructure of the oil industry led to fundamental changes in the landscapes [5]. Population growth due to the oil industry, and later due to internal migration led to an increase in the number of privately owned livestock and, as a result, an increase in the pasture load. Local residents have long used the adjacent slopes for year-round grazing of privately owned livestock, which prevented the restoration of shrubs and trees.

The main load on the landscapes came from the oil industry facilities. Almost everywhere there are roads, slag ponds, oil pipelines. Currently, the number of oil industry facilities has decreased, regulated grazing is underway, which allows us to hope for a reduction in the load due to the regulation of use. Mountain-forest landscapes of the front ranges are experiencing a stage of restoration: forest areas are being compacted, in some places land is being developed for the construction of private houses, mainly for recreational use.

III. Results

Analysis of statistical data for different years on settlement, economic activity and landslide distribution allowed to detail the main factors that directly or indirectly affected the intensity of landslide manifestation. These include: 1) intensive development of oil fields, which affects the change in the seismogenic situation and the state of rocks, 2) changes in the historically established settlement system, the layout of settlements, technologies for building houses of other designs, intra-settlement arrangement of communications and infrastructure with asphalt and concrete pavements, while increasing the number of continuous development centers, 3) changes in the use of land in the host landscape [6]. Development of oil fields. Overlaying oil fields on a landslide map shows that the correlation between them is manifested only in the foothills (Fig. 4). Geological exploration and exploitation of fields leads to a change in the dynamic state of geological structures, the formation of weakened zones and voids, which leads to a violation of the seismic regime in the area. Most of the observed landslide processes on the slopes of the Tersky Range are closely related to oil production processes (mainly the road network to the wells and along the oil pipelines). In the areas of oil production and exploration, slopes are being cut and flooded (Fig. 1). There are several hundred abandoned wells, the injected water overflows from the layers and contributes to the instability of the slopes. The dominant natural complexes here are slopes composed mainly of Neogene deposits of sandstones and clays, partially covered by Quaternary deposits, northern exposure, gentle and medium steep, stepped and hollow, complicated by artificially leveled terraces and roads of the oil industry complex, under mountain forest vegetation of oak, small forests and shrubs of thorn tree on mountain forest chernozem-like and chestnut soils. Subdominant natural complexes are slopes with shrub steppes on chernozem-like and chestnut soils.

IV. Discussion

Analysis of statistical data for different years on settlement, economic activity and landslide distribution allowed to detail the main factors that directly or indirectly affected the intensity of landslide manifestation. These include: 1) intensive development of oil fields, which affects the change of seismogenic conditions and the state of rocks, 2) change of the historically established settlement system, planning of settlements, technologies of construction of houses of other designs, intra-settlement arrangement of communications and infrastructure with asphalt and concrete pavements, while increasing the number of continuous centers of development, 3) change in land use in the host landscape. Development of oil fields [7]. Overlaying the landslide map of oil fields shows that the correlation between them is manifested only in the foothill areas (Fig. 2). Geological exploration and exploitation of fields leads to a change in the dynamic state of geological structures, the formation of weakened zones and voids, which leads to a violation of the seismic regime in the area. Most of the observed landslide processes on the slopes of the Tersky Range are closely related to oil production processes (mainly the road network to the wells and along the oil pipelines). In the areas of oil production and exploration, slopes are being cut and flooded. There are several hundred abandoned wells, the injected water overflows from the layers and contributes to the instability of the slopes [8]. The dominant natural complexes here are slopes composed mainly of Neogene deposits of sandstones and clays, partially covered by Quaternary deposits, northern exposure, gentle and medium steep, stepped and hollow, complicated by artificially leveled terraces and roads of the oil industry complex, under mountain forest vegetation of oak, small forests and shrubs of thorn tree on mountain forest chernozem-like and chestnut soils. Subdominant natural complexes are slopes with shrub steppes on chernozem-like and chestnut soils.

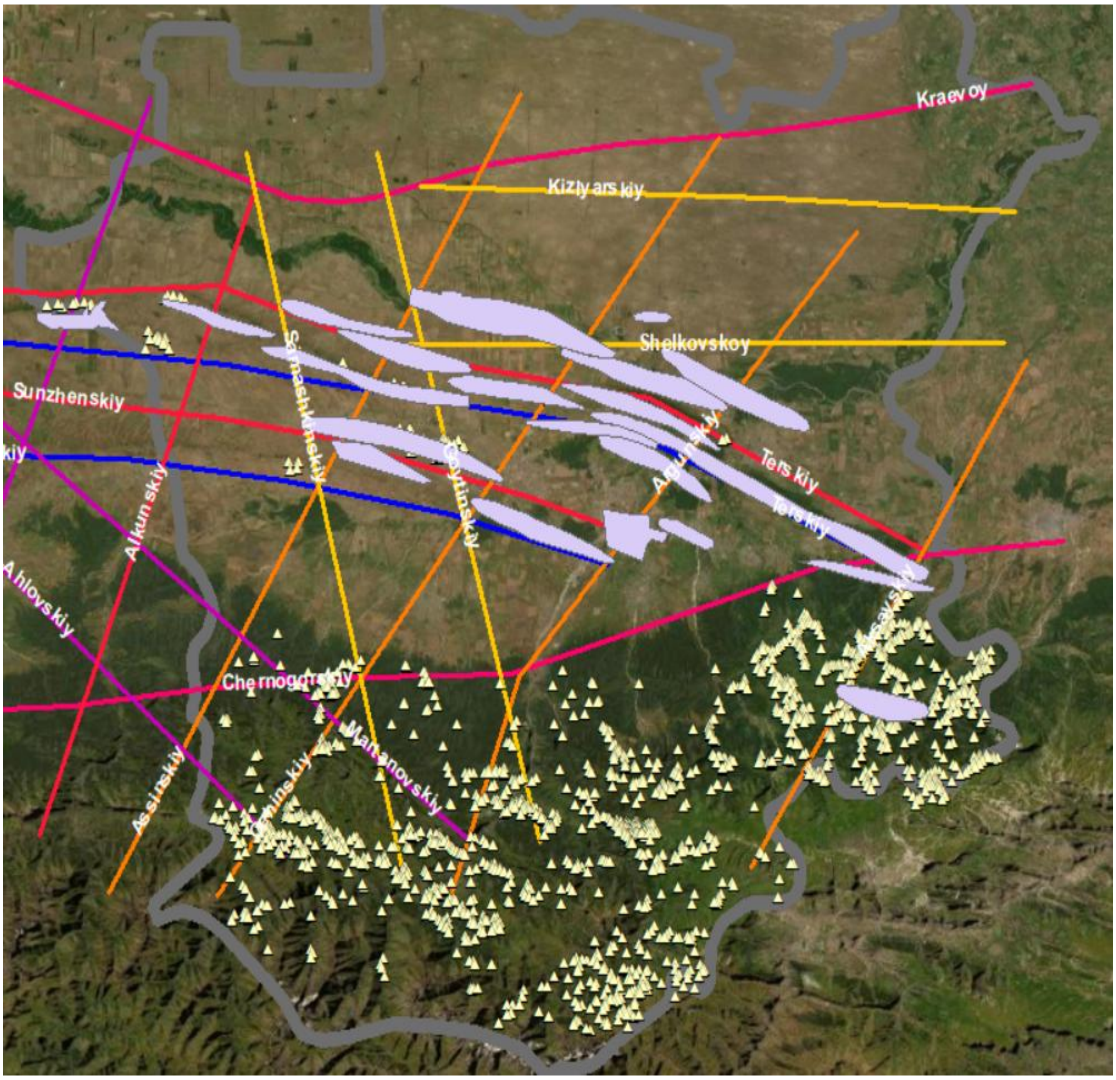

Figure 2: *Landslides (indicated by light triangles), faults (straight lines of different colors) and oil fields (light-colored lenses) in the Chechen Republic.*

A striking example of the impact of land use on landslides is observed in the area of the village of Varanda. After the eviction of the Chechens, Old Believers arrived in these territories, who carried out intensive agricultural activities - arable land with mechanical soil cultivation. As a result, instead of small parcels of arable land and vegetable gardens, which had a terraced nature of distribution, large fields were formed on which the water supply regime of the soils was disrupted [9]. The torrential nature of summer rains contributed to the formation of erosion furrows, subsidence, which disrupted the stability of the slopes. A decrease in the infiltration properties of soils with an increase in water supply led to the occurrence of landslides in watershed areas.

Landslide areas coincide in terms of moisture conditions, fertile substrate with favorable conditions for life. In natural terms, the mountainous territories of the Chechen Republic have a relatively limited number of areas for agriculture and settlement, mainly areas unfavorable for settlement predominate: dissected relief, steep slopes and mountain gorges with turbulent watercourses that wash away these slopes [10]. In the lowlands and midlands, where climatic conditions are relatively favorable for permanent residence, the slopes are composed of loose, rapidly eroding and unstable deposits of clays, argillites and siltstones. Vegetation contributes to the consolidation of landslide-prone areas. However, the very uneven precipitation regime, especially in early spring, when the vegetation cover has not yet formed, serves as a factor in increasing landslide manifestations [11].

Fertile fine-grained substrate has always been attractive for development under arable land. Near such areas, which also had outlets of groundwater used for economic needs and irrigation, people settled, founded new villages (Fig. 3). Traditional Chechen houses in the low-mountain and partly mid-mountain zone, where rocky rocks were rare, were built of light material (usually a wooden frame, and the filler consisted of straw and clay). The roads were unpaved and narrow, they were winding and fit into the relief. Houses and outbuildings also fit into the relief, buildings were scattered along the slopes, and roads were rare. In the second half of the 20th century, with the use of heavy machines, roads began to expand, heavy construction and agricultural machinery passed along them [12]. Houses, starting with foundations and walls, began to be built using brick and concrete structures, which significantly increased the load on the soil. The increased need for water and energy (gas, electricity) led to the emergence of linear water and energy supply facilities. All this together significantly increased the load on the host landscape in landslide areas.

Figure 2: *Landslide processes near the Gendargen-Shunoy road*

The distribution of landslides and the features of settlement and land use differ in different high-altitude landscape zones; the most extensive landslide areas are confined to low-mountain densely populated landscapes of the eastern part of the Chechen Republic. Several types of cause-and-effect relationships are distinguished in the "landslide occurrence - economic activity" system: on the one hand, landslide areas are characterized by good water supply and the presence of fertile substrate for agriculture [13]. On the other hand, landslide processes cause destruction and force the population to migrate to cities and plains. The main factors that influenced the connections in the "landslide occurrence and anthropogenic activity" system should be considered changes in settlement and land use caused by socio-political events of the last century.

Abstract

The relevance of the scientific issue concerns with the search for scientific methods of technology-related emergencies prevention. Those caused by dumping and disposal of wastes in the natural environment. The purpose of the study is to find new approaches for preventing the discharge of oily waste into water bodies and soil caused by stationary and mobile sources of pollution. At the annual international scientific and practical event "Integrated Safety-2024" we reported on new approaches to preventing excessive pollution of natural objects with oil waste. However, it creates risks of man-made emergencies with unfavourable environmental consequences for water bodies. Our report was highly appreciated by the participants. The authors plan to test and adapt the proposed technologies and methods for preventing the formation and disposal of oily wastes as sources of increased environmental danger.

Keywords: environmental safety, oily waste, pollution, magnetic fluid, recycled raw materials, utilisation

I. Introduction

Industrial, energy, and transport facilities are factors of increased environmental hazard. Environmental hazard is a source of technological emergencies risk concerning with unfavourable socio-economic, environmental, and other consequences. The factors of such hazard are emissions of harmful substances into the air, discharges of polluted wastewater, and the formation of toxic waste [1-5].

One of the most widespread and dangerous environmental pollutants is oily waste. Indeed, oil sludge, oily wastewater, waste oil, and a wide range of other similar wastes generated practically by all industries and sectors of the economy [6-9]. In addition, the recycling of iron-containing waste as a result of metallurgical, machine-building, and chemical industries is currently a serious problem. However, these wastes contain valuable components that can be used as raw materials for the production of sought-after products.

In this paper authors consider the high relevance of the posed scientific problem and present the results of their research.

II. Methods

Research methods are based on collected information system analysis. It allows us to substantiate the choice of the algorithms and tools for solving the scientific issue. Additionally, to find strategic ways for solving the stated issue in accordance with the logical chain: object - subject - research context, we use the conceptual analysis and numerical methods of data processing.

The research is also based on the experimental data obtained during establishing and validation of water purification technology. This technology allows ones to remove oil products using magnetic liquids recycled on industrial waste.

III. Results

This particular research is two-staged one. The first its objective is related to the prevention of negative impact of oil-containing wastes and effluents from water transport on drinking water sources. Therefore, we solved this by development new approach and technologies for treatment of oily waste and effluents (by separation of oil sludge and treated wastewater) using magnetic liquids made of industrial waste.

The second its objective is related with the application of magnetic liquids obtained using industrial wastes [10-13]. This objective refers to the development of oil-containing wastewater treatment technology (by separation of oil waste and treated wastewater).

Nowadays, the following method of water purification from oil products by magnetic liquids is known: spraying of magnetic liquid through special spraying devices onto the oil film and subsequent collection of "magnetised" oil products by an electromagnetic device.

However, this water purification technology requires large volumes of magnetic fluid. The high cost of industrial magnetic fluids produced from "pure" raw materials is one of the factors hindering the widespread adoption of this technology in terms of economic feasibility. Researchers of Yaroslavl State Technical University have developed and patented environmentally safe technologies for obtaining cheap magnetic liquids using iron-containing industrial waste.

This project was successfully laboratory tested. Nowadays, it is in the industrial testing phase.

The proposed water purification technology is based on magnetisation of oil products with paraffin based magnetic liquids. Magnetised petroleum products are separated by a magnetic field in the process of treating contaminated water with magnetic fluid. The innovative method of water purification has many advantages. Firstly, it effectively removes oil products from water. Secondly, it allows ones to avoid the use of hazardous chemicals. This significantly reduces the unfavourable impact on the environment and humans. Moreover, volumetric water purification by using magnetic fluid is a relatively fast and cost-effective process. It significantly accelerates the water purification process by reducing the time of filtration and sedimentation of contaminants [14-18].

Magnetic fluid is a suspension of magnetic material nanodispersed particles stabilised by a surfactant in a carrier fluid. Three components are required to produce a magnetic liquid: a liquid base, magnetic particles of colloidal size (magnetite), and a stabiliser to prevent the colloidal particles from sticking together. Therefore, taking into account these conditions and limitations, YSTU researchers used iron-containing wastes of metallurgical, machine-building, and chemical industries as raw materials for obtaining magnetic particles.

The proposed technology of obtaining magnetic liquid utilises iron-containing production wastes and provides wider application of the obtained product (for example, for water purification from oil and oil products) due to its significant cost effectiveness.

The magnetic liquids obtained using waste products were characterised by physical and chemical methods of analysis. The saturation magnetisation of ML was 14-17 kA/m, volume fraction 4-6 %, density 800-950 g/dm^3. To confirm the structure and composition of the ML, spectra of the samples (Figure 1) were obtained on a FT-IR spectrometer RX (Perkin Elmer) with an NPVO Spectrum Two attachment in the frequency range of 400-4000 cm^{-1}.

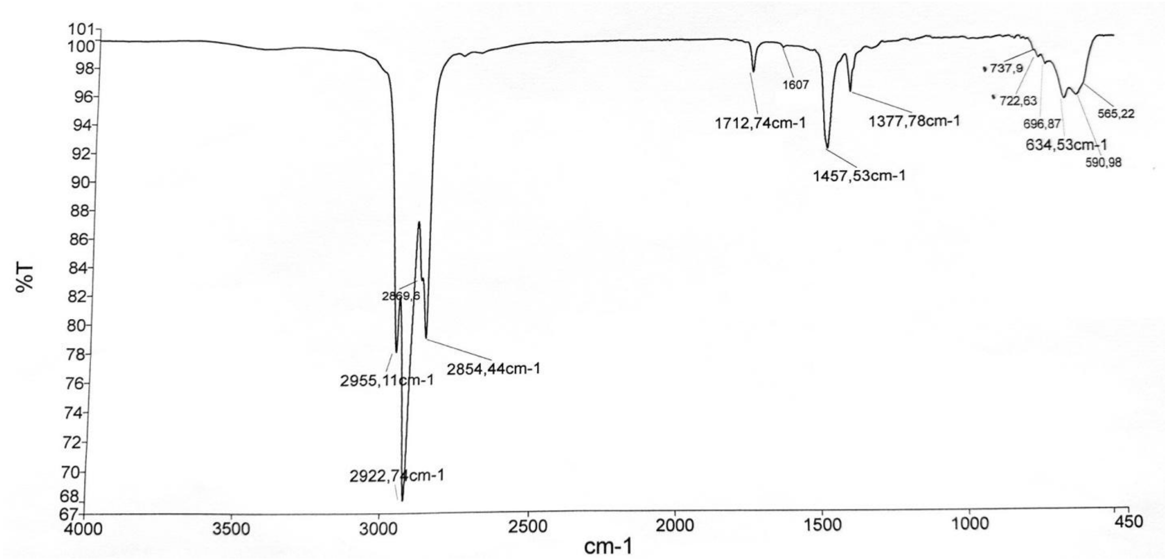

Figure 1: *Infrared spectrum of the magnetic fluid*

In the IR spectrum of the ML sample (Figure 1), there are absorption bands 696.87-565.22 cm^{-1}, which correspond to the Fe-O bond vibrations. This confirms the presence of the mineral form of magnetite in the synthesized sample.

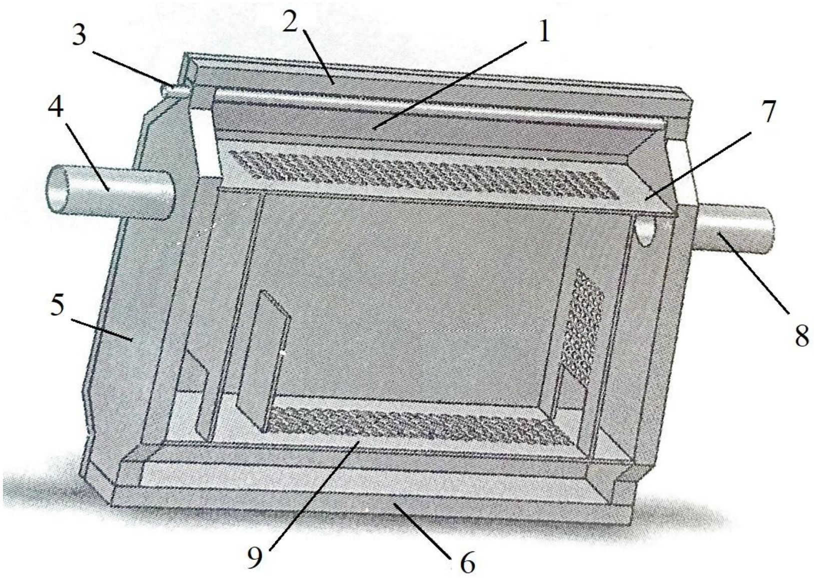
To remove oil products, we used magnetic liquids from production wastes for surface and volumetric water purification. Experiments show the high efficiency of application (90-96%) of the obtained magnetic liquids for "magnetic" water purification from oil products. The residual content of oil products in the water is less than 8 mg/dm^3 compared to industrial oil traps, where the residual content of oil products is more than 50 mg/dm^3.

Implementation of the proposed technology will cause a reduction in the impact of heavy metal ions and petroleum products on water bodies. This will improve water quality, reduce population morbidity and mortality, decrease costs on drinking water treatment, contribute to aquatic ecosystems conservation, increase the yield of fish economic water bodies, and reduce pollution of coastal areas by heavy metals and petroleum products. Hence, heavy metals and petroleum products extraction, treatment, and disposal reduce the environmental impact. Technical specifications and technological regulations for obtaining magnetic liquid and its application were developed and approved during the conducted research on the process of oil products collection on water surface by magnetic liquid.

In addition to surface water purification, experiments on volumetric purification of water from oil products were conducted. We use the apparatus described in the patent [19] (Figure 2).

The magnetofluid cleaner is a cell in which the side steel walls are set parallel to each other and taper at the top at an angle of 45°. Magnets are attached to them, arranged in two tiers along the entire length of the wall, according to the north-south pole arrangement in order to close the magnetic flow. The magnetic field at the top of the cell is larger than in the gap between the permanent magnets. It allows the magnetised petroleum product to be trapped. There are also separating plates with holes in the cell located above and below the magnets. They divide the cell into three layers: upper (magnetised petroleum products), middle (metal chips), and lower (heavy petroleum products) one.

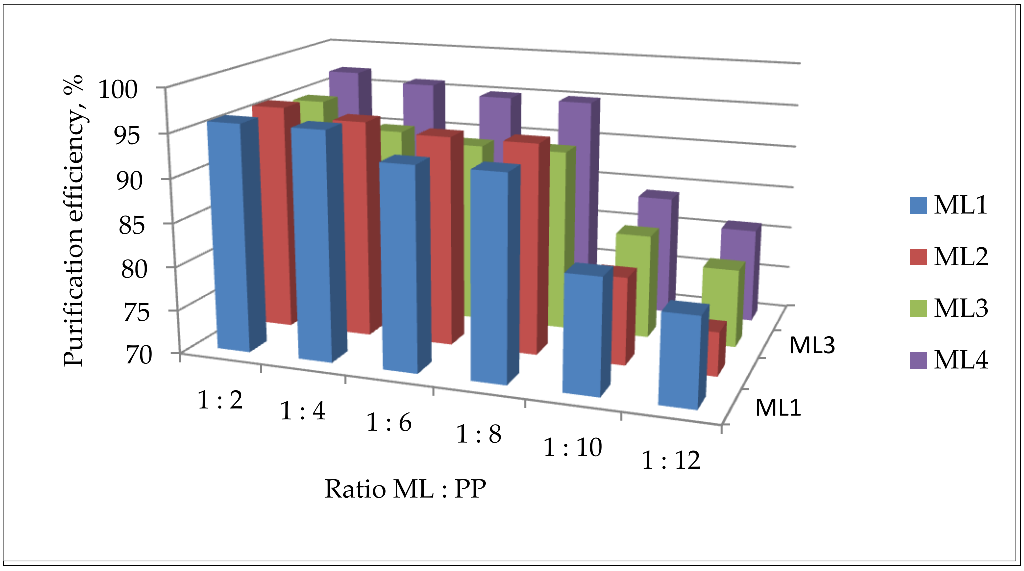
The principle of magnetic-liquid separator-cleaner operation is quite simple and highly efficient. Wastewater contaminated with oil products mixed with magnetic liquid, enters the unit body through the inlet pipe *8*, where ferromagnetic material is located. Oil droplets in contact with the chips are adsorbed on their surface, forming a thin layer due to the hydrophobic (water repellent) property of ferromagnetic chips and the oleophilic (attractive) property of oil products. The drops of petroleum product held on the surface of the ferromagnetic material chips float to the upper layers of the chamber under the action of Archimedes' forces arising in the gravitational field. As the polluted effluent moves through the apparatus, the content of oil products in the water gradually decreases due to coalescence and adsorption processes. The purified water is discharged from the chamber through branch pipe *4*.



1 – lateral steel wall; 2 – top cover; 3 – tube for magnetised oil product pumping out; 4 – tube for treated water pumping out; 5 – lateral wall; 6 – bottom; 7 – top plate with holes and two partitions; 8 – tube for water supply with magnetised oil product; 9 –bottom partition with holes and limiting partition

Figure 2: *Wastewater treatment plant for treatment of oil products using magnetic fluid*

The ratio: magnetic liquid / oil products changed during the experiments. The results of the experiments are presented on the diagram (Figure 3).



ML-1 is a magnetic liquid obtained from cupola dust, PAO Avtodiesel, Yaroslavl, Russia; ML-2 is a magnetic liquid obtained using waste from Olcona – Olenegorsk Mining and Processing Plant, Murmansk region, Russia; ML-3 is a magnetic liquid obtained using gas cleaning waste from OAO Severstal, Cherepovets, Russia; ML-4 is a magnetic liquid obtained using pure components.

Figure 3: *Experimental results of volumetric water purification using liquid magnets*

According to the diagram analysis, the optimum ratio of magnetic fluid to oil products during cleaning is 1 : 8; it provides cleaning efficiency in the range 91 %-95 %.

Collected magnetised petroleum products can be used as an additive to the rubber compound. It will result in improved rubber deformation and strength properties [20].

Moreover, the current methods of oily waste utilisation are their burning and landfilling. It causes the loss of valuable components and secondary pollution of the environment. More than 400 thousand tonnes of such waste have been accumulated only in the Yaroslavl region, Russia. Hence, this issue is very urgent both for the region and the country.

In this regard, the pond sour tar of Yaroslavl experimental industrial oil and oil plant named after D.I. Mendeleev, Yarioslavl region, Russia and oil sludge of OAO Slavneft-YaNOS (Slavneft-YANOS PJSC), Yaroslavl, Russia Flottweg plant have been the objects of long-term studies of oil waste reuse in the production of oil-containing products.

YSTU Department of Labour and Nature Protection researchers have developed a technology of producing binding materials for road construction with the use of oil-containing waste - bitumen pastes. Moreover, they determined the quality indicators for their assessment; the obtained bitumen pastes fully completely correspond to the standard requirements.

Indeed, we introduce binding materials obtained using oil-containing industrial wastes.

Development stage - the project has been successfully laboratory tested. Nowadays, it is at the stage of industrial testing at construction sites.

Unlike road bitumen, the use of bitumen pastes based on the following proposed technology:

- full adhesion to the base;
- it is allowed to spill bitumen pastes on the moistened surface;
- the possibility of varying its composition by qualitative indicators required for each individual type of work;
- lower energy consumption due to absence of necessity to maintain high temperatures;
- use of bitumen emulsions at temperatures 30-70 °C makes its application safe.

The economic effect of the research is achieved in decreasing of enterprises payments for storage of oil-containing wastes in sludge collectors, expansion of raw material base for production in Yaroslavl region, Russia, and decreasing of finished products (bitumen paste and asphalt-concrete compositions) production costs.

The approximate prime cost of prepared bitumen paste on the basis of oil-containing waste is about 3, 000 RUB. For instance, the analogue produced by the enterprise OOO Doros, Yaroslavl, Russia is 16, 000 RUB.

Hence, the collected and treated oil products after their separation out of the sub-slope (bilge) waters can be subjected to utilisation, namely - regeneration. Regeneration is the restoration of product useful properties to the level of secondary raw materials, or commercial product suitable for reuse in production and economic processes and operations.

IV. Discussion

The authors proposed ways of solving one of the modern urgent issues - prevention of pollution of drinking water sources surface with oil wastes and oily effluents. It causes threats and risks of man-made emergencies. Our solutions imply prevention of hazardous impact on water bodies by utilisation of oily waste and effluents through innovative technology for oil products separation coming out of the sub-slope water and their reuse as secondary raw materials for wide range of products production.

According to YSTU practical results, modified magnetic liquids effectively remove oil products on water providing high quality of its purification through the separation.

The authors conducted morphological and physic-chemical analyses of the composition and structure of oil waste separated out of waste water (after appropriate treatment (cleaning, separation, drying, resizing). According to their technical and operational characteristics, the following separated oil products can be reused as secondary raw materials to produce a wide range of products: oil-containing lubricants, pastes, additives in rubber mixtures and construction materials (asphalt concrete plants), etc.

The study also considers: environmental acceptability, technical feasibility, and economic efficiency of the proposed approach to the separation and purification of oily mixtures generated during repair and operation of water transport. It also proposed the practical application in water treatment facilities on ships. The final decision on the application of the proposed method and technology of oil waste separation using magnetic liquids will be made after additional researches, their comprehensive discussion, and approbation in the water transport system.

THE INVESTIGATION OF THE EFFICIENT OPERATING MODES OF VARIOUS SOURCE HEAT PUMPS IN THE HEATING SYSTEMS OF INDIVIDUAL RESIDENTIAL HOUSES IN KHANKENDI

Sevinj Babayeva
•
Azerbaijan State Oil and Industry University
babayeva_sevinc64@mail.ru

Abstract

*The article investigates the efficiency of various-source heat pumps in the heating system of an individual residential house located in the Nagorno-Karabakh economic zone, specifically in Khankendi. The parameters characterizing the heating supply scheme, along with all the equipment and components related to the scheme, have been calculated utilizing the GeoT*SOL simulation software. This program is one of the modern simulation tools used for the planning and design of heating pump systems. As an example, a private residence in Khankendi has been studied, and schematic diagrams for four different-source heat pump systems for the house's hot water supply and heating have been proposed. Seasonal performance indicators, energy efficiency, losses, solar contributions, efficiency, and more have been computed through computer simulations. The most efficient system has been identified.*

Keywords: alternative energy, heating equipment, GeoTSOL, ground-source, air-source, soil-source heat pump, modeling, simulation

I. Introduction

The 29th session of the Conference of the Parties to the United Nations Framework Convention on Climate Change (COP29) will be held in Azerbaijan this year. In 2024, hosting COP29 in Azerbaijan, one of the largest and most significant international events in the world, marks yet another notable triumph for President Ilham Aliyev. This stands as the most significant success of the Republic of Azerbaijan's foreign policy following our leadership in the Non-Aligned Movement and membership in the Security Council. The Republic of Azerbaijan aims to reduce greenhouse gas emissions by 35% by 2030 compared to the 1990 levels, with even more ambitious targets set for the period after 2030, aiming for a 40% reduction by 2050.

President of the Republic of Azerbaijan has declared the liberated territories as the "Green Energy" zone, with the goal of transforming these areas into a "Net Zero Emission" zone by 2050. This initiative reflects Azerbaijan's commitment to sustainable and environmentally friendly practices [1,2,3].

Within the framework of creating Green Energy Zones in the liberated territories, various measures are planned, including the production of electricity from restored energy sources, energy efficiency initiatives, installation of energy devices (especially solar panels) on building roofs, utilization of solar energy-based LED lamps for street and road lighting, use of recovered energy technologies in heating, cooling, and hot water supply, implementation of smart energy management technologies, and measures for the energy-efficient management of traffic lights.

Despite Azerbaijan's wealth in oil and gas reserves, special attention is being given to the development of the renewable energy sector. In the near future, Azerbaijan aims to transform into an exporter of green and hydrogen energy. Based on agreements and memorandum of understanding signed with leading international green energy companies and external investors, the restored energy production in Azerbaijan is projected to reach 10 gigawatts in the coming years.

Global issues and tasks are addressed and analyzed by extensively studying world experience. In the realm of science, modern advancements, particularly in technology, are applied to the utilization of alternative energy. Research findings are applied to relevant areas, results are analyzed, and effective methods and approaches are selected.

II. Results

The aim of this research is also to address the heating demand of individual residential houses in the city of Khankendi through the use of heat pumps. There are several methods for researching the effective operating modes of heat pumps. Among them, the most modern and effective method providing rapid results is computer simulation.

There are several simulation programs available for the calculations of heat pump systems. Programs used for the calculation of heat pump systems include GeoT*SOL, EnergyPlus, TRNSYS, DesignBuilder, HAP, HEAT2, RETScreen, etc. Each simulation program has its own specific features. In this research, the process of heating the individual residential house in the city of Khankendi through the use of a heat pump system has been investigated using the GeoT*SOL simulation program [4]. This program is a professional tool widely applied in developed European countries for the planning and design of heat pump systems. GeoT*SOL allows selecting various system types and components to achieve the best possible seasonal performance. It enables the calculation of energy consumption and costs to achieve optimal seasonal performance. GeoT*SOL simulates heat pump systems alongside solar thermal collectors and conventional boilers as required.

The analysis of simulation results revealed the significance of pre-calculating parameters characterizing the heating system during the modeling and exploration of "smart village" and "smart city" projects in developed countries [5-9]. As a result of the simulation, it has been clarified through the comparison of the obtained results which scheme will operate more effectively.

The heating pump environment has been selected to include geothermal probes, geothermal collectors, air, and groundwater. Over the course of one-year, dynamic minute-by-minute simulations have been conducted to calculate seasonal performance factors, energy consumption, losses, solar fractions, efficiency, and other relevant parameters for the entire heating pump system. The simulation process was conducted for one system type and four different heat sources. The operating mode of the heat pumps was accepted in monovalent mode. The simulation results yielded the following insights.

The city of Khankendi is located at approximately -46.77° E longitude and 39.83° N latitude. The annual sum of global irradiation has been calculated through simulation and is determined to be 1,498,465 Wh/m². Four different heating equipment schemes relying on various heat sources have been selected for an individual residential house with the same parameters. The aim of the research is to investigate which heat source is more effective for space. For this purpose, all parameters of each scheme were calculated, and all values were compared. According to the schemes provided in Figure 1, the following heating equipment configurations have been selected:

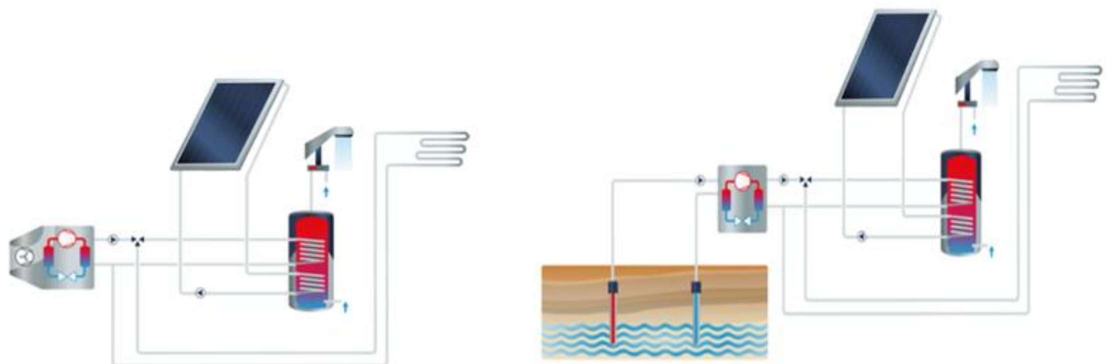
a) Air-source heat pump for hot water supply and heating system,

b) Ground-source heat pump for hot water supply and heating system,

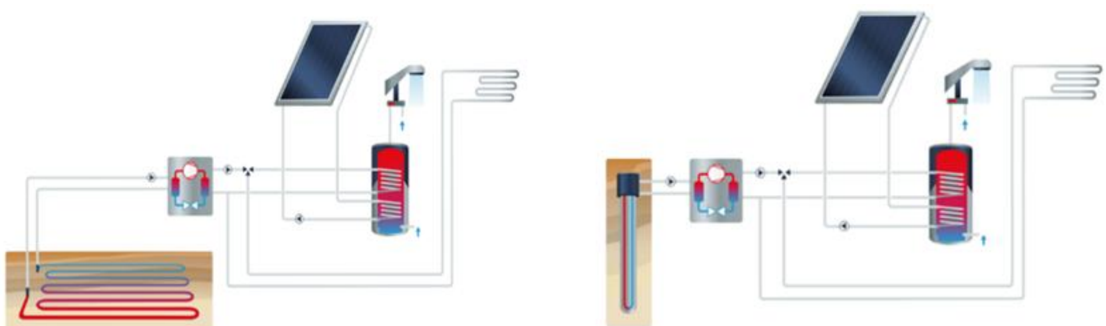
c) Soil-source, collector-type heat pump for hot water supply and heating system,

d) Soil-source, probe-type heat pump for hot water supply and heating system.

There are several operating modes for a heat pump: monovalent mode, monoenergetic mode, bivalent mode, bivalent parallel mode. In the investigated heating equipment system, the heat pumps operate in monovalent mode. In this mode, the heat pump serves as the sole heat source for both space heating and domestic hot water. The heat source should be designed to operate throughout the heating season; in monovalent mode, the heat pump heats the entire space to the lowest external temperature. In this mode, a solar collector is used as the secondary heat source.



a) Air-source heat pump b) ground-source heat pump



c) Soil-source, collector-type heat pump d) soil-source, probe-type heat pump

Figure 1: *Schemes of heating equipment with various heat sources*

The use of solar collectors in heat supply is related to the abundance of solar energy, its inexhaustibility, accessibility, and environmental cleanliness. For the heating equipment of residential buildings, primarily small solar systems are employed. Such systems include solar collectors, storage tanks, circulation pumps, and other auxiliary devices. Computer simulation has been utilized to calculate all specific characteristics of the solar collector for Khankendi.

The energy used for space heating and domestic hot water supply, measured in kilowatt-hours per hour (kWh/h), based on various sources, is shown in Fig. 2. Since the same space is selected for each scheme, all parameters are identical for this position.

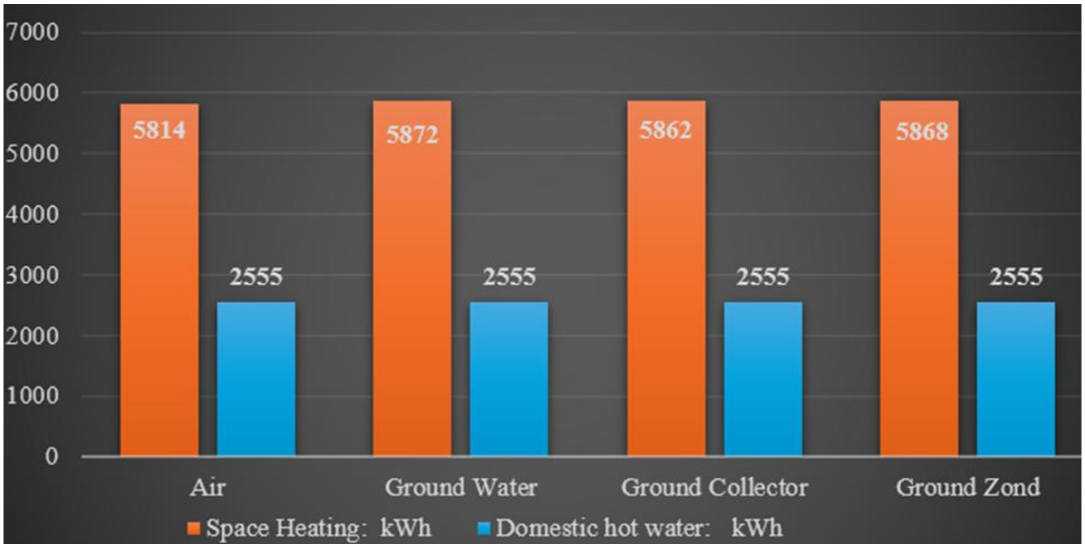


Figure 2: *Energy Used for Space Heating and Domestic Hot Water Supply (kWh/h)*

For each heat source, annual produced energy values have been calculated. The analysis of the results indicates that, although with slight differences, ground-source heat pumps are theoretically preferable.

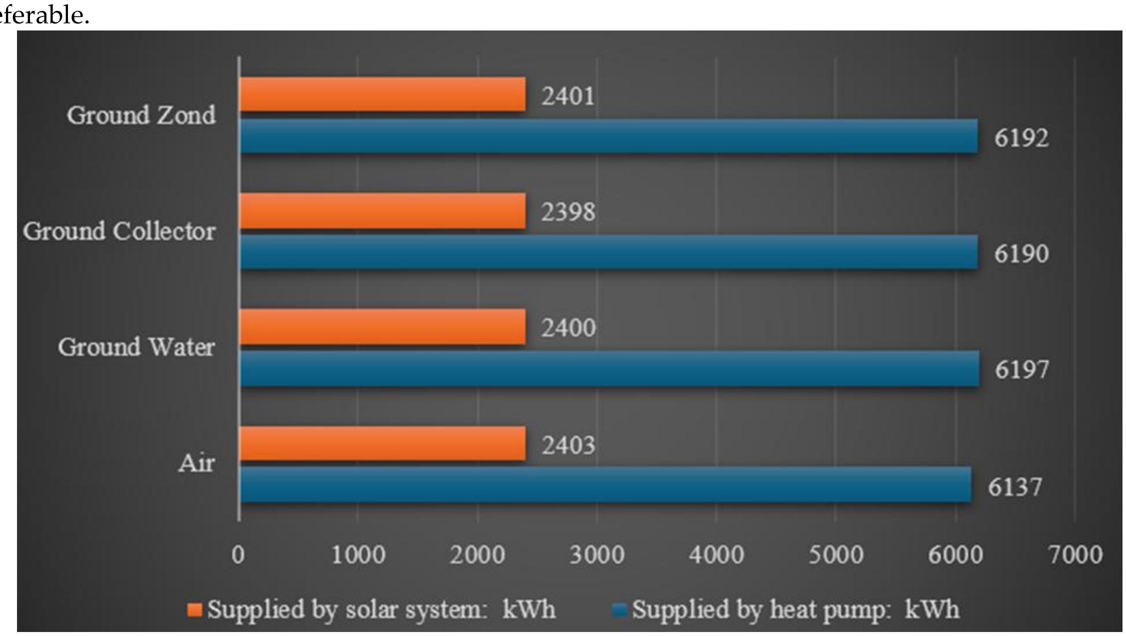

Figure 3: *Energy values produced by various heat sources (kWh/h)*

The efficiency of the heat pump operation is characterized by its performance factor. Fig. 4 illustrates the results obtained from computer simulation for the performance factor of the heat pump, the heat pump system, and generator system with the heat pump.

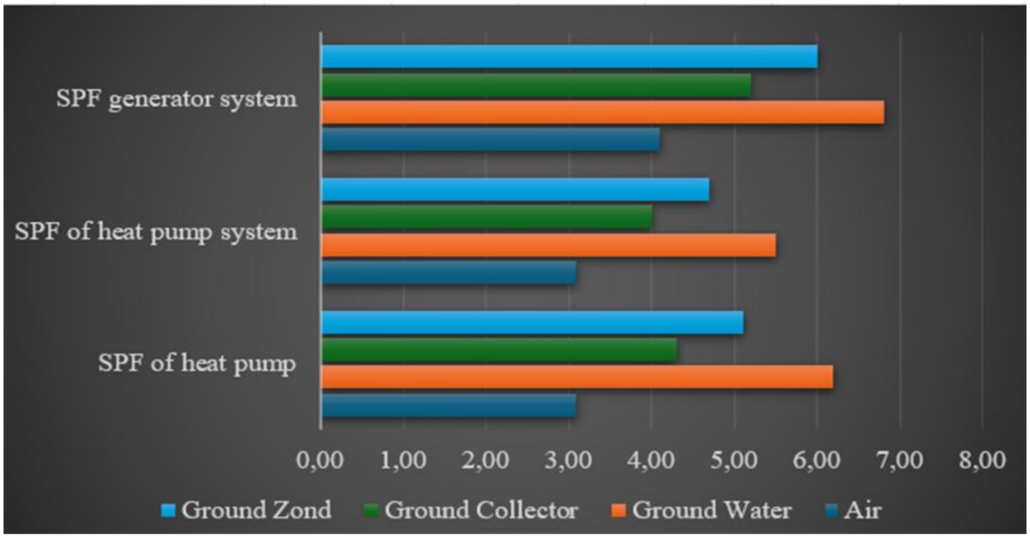

Figure 4: *Performance factor values*

In the comparison of performance values based on schemes, the position related to the ground-source holds an advantage. Namely, the calculated values for the ground-source heat pump, the heat pump system, and the generator system are lower than the others.

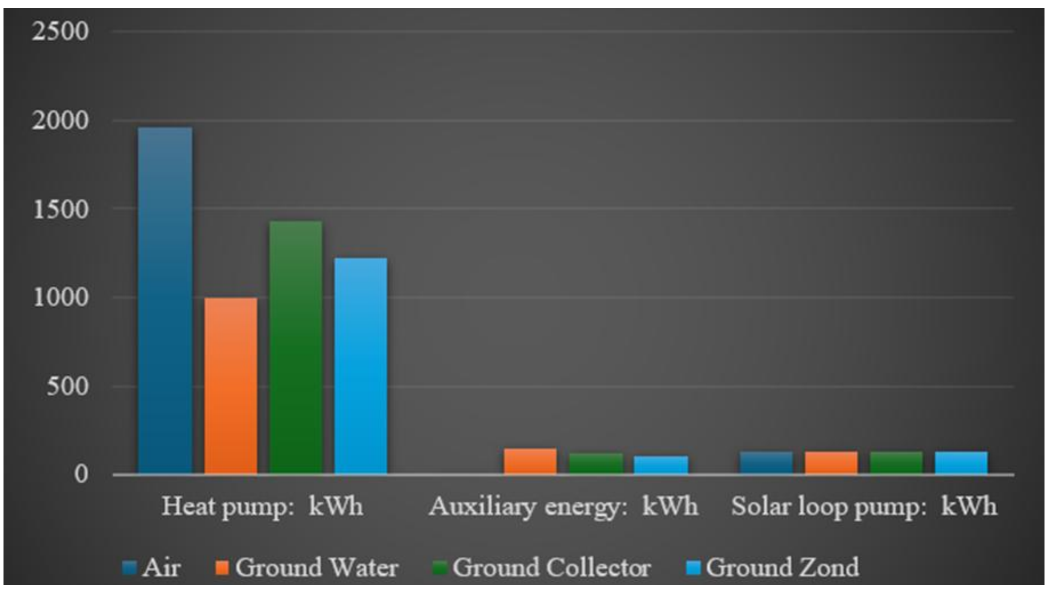

Figure 5: *Annual energy consumption of heat sources*

In each scheme, the heat source consumes electrical energy. According to the simulation, the energy consumed by each energy source in each scheme was calculated and compared. In terms of these parameters, the ground-source heat pump scheme stands out. The annual energy consumption of the energy sources in the corresponding schemes is minimal here (Fig. 5).

Table 1 presents the values of system losses. One of the parameters characterizing the efficiency of the system is the annual tank losses. In this regard, there is not much variation in tank losses among various source heat pump systems.

Table 1: *System losses*

	Air	Ground Water	Ground Collector	Ground Zond
Tank losses: kWh	379	379	380	379
...fraction of solar tank losses: kWh	157	158	158	157
Solar loop piping indoors: kWh	400	400	400	400
Solar loop piping outdoors: kWh	70	70	70	70

Using various source heat pumps in the heating supply scheme, all parameters related to the solar component have been calculated, as presented in Table 2.

Table 2: *Solar fraction of the heating equipment system*

	Air	Ground Water	Ground Collector	Ground Zond
Solar fraction: %	28,10	27,9	27,9	27,9
Solar fraction DHW: %	87,40	87,3	87,3	87,4
Efficiency of solar system: %	23,30	23,3	23,3	23,3

The energy gain of each system is one of the main factors influencing its efficiency. In Fig. 6, the primary energy gain values of the system, including the energy transferred by the collector and through the collector loop, are compared. Here, the most favorable values belong to the ground-source heat pump scheme.

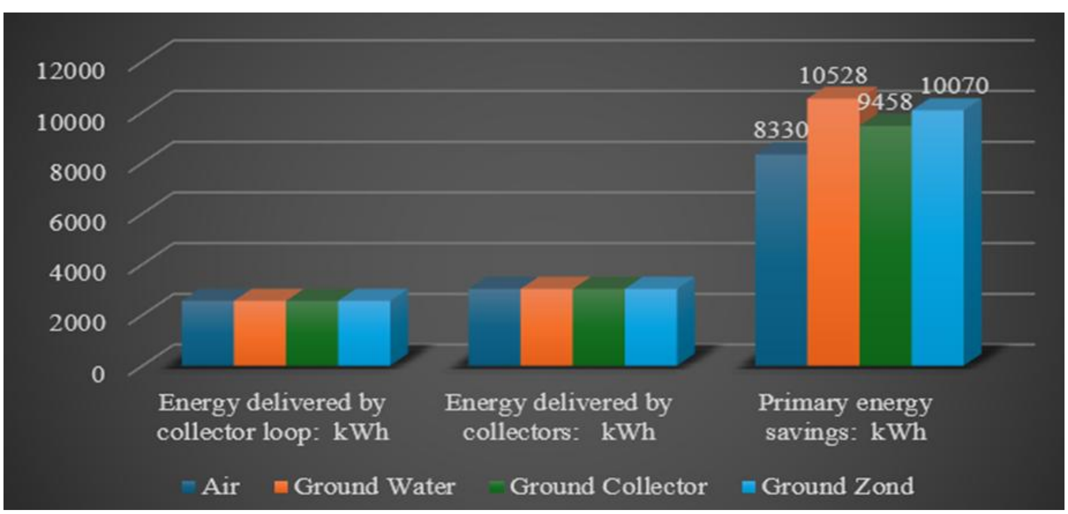

Figure 6: *Primary energy gains in systems*

The world reached a new anti-record in CO_2 emissions into the environment from energy production in 2022. The implementation of these schemes significantly reduces the amount of CO_2 emitted into the environment. In this context, the ground-source heat pump scheme holds an advantage (Fig. 7).

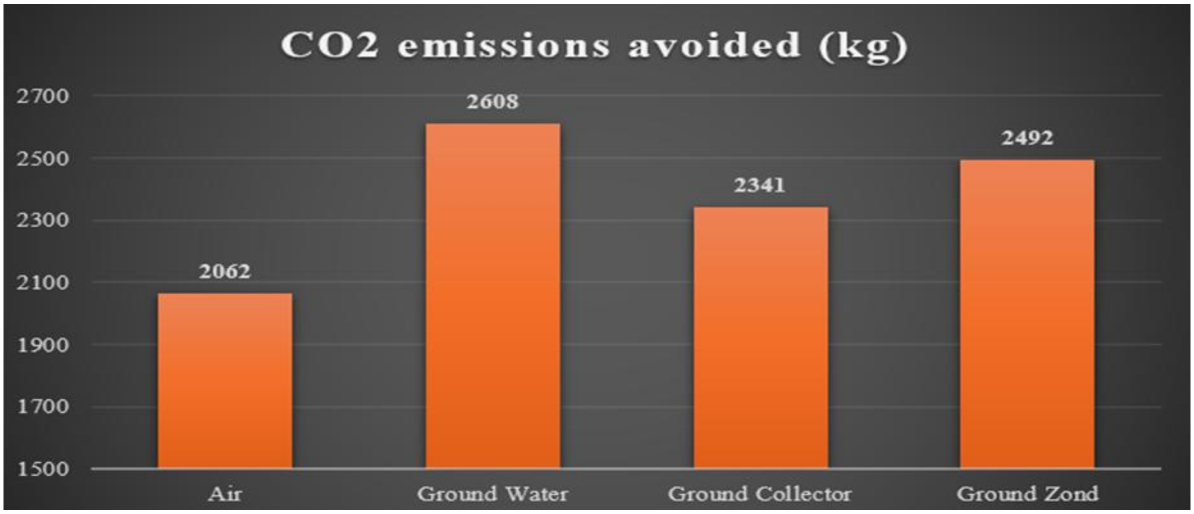

Figure 7: *Amount of captured CO_2 emissions*

Global warming has currently turned into a human catastrophe, primarily due to the disruption of the atmospheric heat balance. The problem arises from the increasing pollution of the environment. One of the main factors contributing to environmental pollution is the emission of flue gases from the combustion of fossil fuels used to obtain electricity and heat energy [7]. In addition to being energy-efficient in utilizing alternative energy, including heat pumps in heating systems, the simulation method prevents a significant amount of carbon emissions from being released into the atmosphere. The advantage of research conducted through the simulation method lies in the rapid and accurate acquisition of results. Heat pump systems do not have a negative impact on the environment during their operation. Combustion of fossil fuels is eliminated during their use, and no noise is emitted during their operation. There is no need for additional expenses during their utilization, and their operational lifespan is long. The application of heat pumps in the heating systems of buildings and for space cooling will lead to a reduction in heating and cooling expenses. There will be a high demand for heat pumps in the economic zone of Karabakh, especially considering the forecasts for the increase in electricity and fuel prices and the abundance of individually constructed houses in this region.

Conclusion

1. The heat pump system is an environmentally friendly heating and cooling system from an ecological perspective. The applied heat pump does not pose an ecological threat to the people living in the environment.
2. The heat pump operates continuously and does not require special attention.
3. In the Karabakh region, specifically in Khankendi city, the possibilities of using heat pumps from various sources for the heating equipment of individual residential houses have been explored, identifying the type with high energy potential.
4. In the Karabakh region, in Khankendi city, the research has shown that the use of ground-source heat pumps is more effective in heating supply, considering the climatic conditions.

5. The fundamental scheme of the heat pump system is provided through computer simulation. Each characteristic parameter of the devices constituting this system has been calculated, and devices produced by the factory have been selected.

6. As a result, energy produced and used, required power, losses, etc., have been calculated for both the system and each component.

Khvedelidze.i@gmail.com

Abstract

In the era of developed industry, the contamination of the environment with radioactive elements and heavy metals turned out to be particularly dangerous, which became the cause of significant social problems in densely urbanized areas. This is evidenced, for example, by the special scale of oncological diseases and frequent genetic mutations.

Keywords: soil contamination, diffusion model, soli pollution, mining activity

I. Introduction

In the recent past, radiation pollution often occurred in particularly densely urbanized areas of industrial zones in Georgia. At present, the level of radiation contamination of the inspected part of Rustavi territory with Cs-137, Sr-90 and K-40 radioactive elements is not alarming. However, a reliable representation of the retrospective picture of the radiation situation requires an assessment of the change in the level of soil contamination in time and space. For this, we need to know the power of the pollution source and its duration. It is natural that environmental pollution develops both in space and time. Creating an adequate mathematical analogue of the process of spreading pollution in the soil is a task of particular difficulty. Its exact analytical solution is impossible, although there are approximate solutions, on the basis of which it is possible to correctly model the dynamic picture of pollution. In contrast to atmospheric pollution, the process of diffusion in the soil is significantly influenced by the orography of the earth's surface, the agrochemical nature of the soil and its magnetic properties. When modeling the spread of soil surface pollution in time and space, it is permissible to ignore the effect of the convection flow of surface waters.

II. Methods

In general, it is fair that the migration process of chemical pollution in the soil is significantly determined by the slow movement of groundwater, the so-called. Filtration, which is affected by atmospheric precipitation. In addition, in contrast to atmospheric pollution, the process of diffusion in the soil is significantly influenced by the orography of the earth's surface, the agrochemical nature of the soil and its magnetic properties. Despite such diversity, in some cases it is acceptable that some of these factors are not equally effective. When modeling the spread of soil surface pollution in time and space, it is permissible to ignore the effect of the convection flow of surface waters. Depending on the terrain, it is also possible to use the non-stationary diffusion equation.

III. Results

This general feature of the solution of the diffusion equation represented by Fourier components can be useful for the approximate retrospective reconstruction of the dynamic picture of pollution in the central park of Rustavi. It is obvious that for an approximate reconstruction it is enough to interpolate the measurement results separated by a certain time interval by means of the given graphic representations as palettes. In such a case, it becomes possible to specify the approximate date of the initial moment of pollution, as well as the prediction of the moment of leveling to the characteristic background value of surface soil pollution in the future.[1] For example, in the case of an orographically simple surface, the approximation of azimuthal symmetry is physically permissible

$$\frac{\partial K}{\partial t}=D\left(\frac{\partial^2 K}{\partial r^2}+\frac{2}{r}\frac{\partial K}{\partial r}\right),\ t>0 \quad [1]$$

Where, k is the concentration, D is the diffusion coefficient, t is the time, r is the radial coordinate. We can consider two models.

$$T=\left(\frac{n\pi}{R}\right)^2 Dt \geq 0.4 \ [2].$$

In the first case, the circle of initial concentration of chemical pollution. The distribution will be constant. In the second case, at the initial moment we will have point pollution. If we assume that there is no chemical pollution at the boundary, for both models of initial pollution we will have a suitable boundary condition of normalized background value: K(R,t)=0. In general, both variants of are suitable for modeling the dynamic change of chemical pollution on the Earth's surface and in the soil. represent the qualitative-quantitative visualization of the solution for both variants of the condition [2]. It is obvious that for an approximate reconstruction it is enough to interpolate the measurement results separated by a certain time interval by means of the given graphic representations as palettes [3]. In such a case, it becomes possible to specify the approximate date of the initial moment of pollution, As well as the prediction of the leveling moment of soil surface pollution to the characteristic background value in the future.

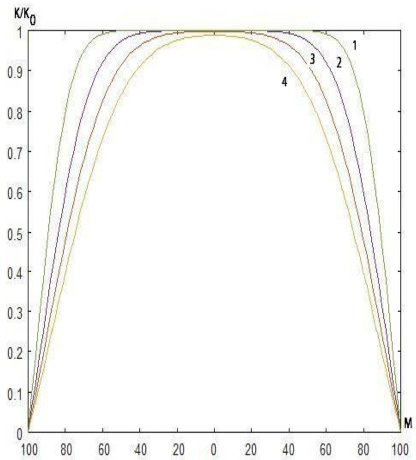

Figure 1: *Figure caption*

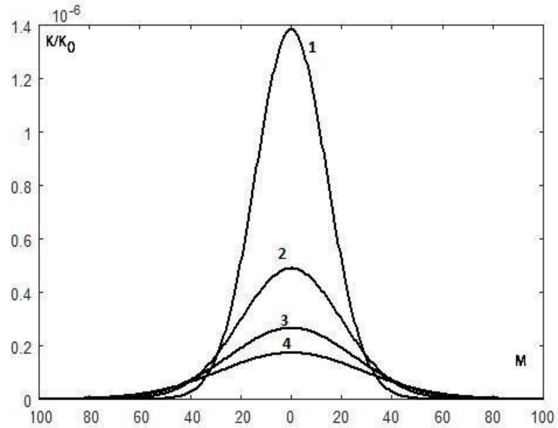

Figure 2: *Figure caption*

IV. Discussion

For the completeness of the analysis, Fig. 3 shows the history of the first graph of Fig. 2. togram (n=20), and in Fig. 4 - the corresponding percentage spread. It should be noted that qualitative information regarding the physical purpose of the immeasurable parameter T is revealed, as the effect of the diffusion coefficient in combination with time becomes evident.[4] Approximation of the ratio of pollution levels by means of the given graphic visualization roughly, However, quite correctly, it allows to determine the quantitative characteristic of the decrease of pollution intensity in time and space.

CLIMATE CHANGE IN MOUNTAINOUS REGIONS AND ITS IMPACT ON THE PHYSICAL DEVELOPMENT OF YOUNG PEOPLE: PROBLEMS AND PROSPECTS

Svetlana Moryakina, Vakha Anzorov
•
Kadyrov Chechen State University, RUSSIA
s.moriakina@yandex.ru

Abstract

This study examines the implications of climate change in mountainous regions on the physical development of young people. As climate patterns continue to shift, mountainous areas are experiencing alterations in temperature, precipitation, and seasonal cycles, which can significantly affect the growth and health of youth populations. The research highlights various problems arising from these changes, such as increased susceptibility to respiratory and cardiovascular diseases, altered nutrition due to changes in local agriculture, and the psychological impacts of environmental stressors. Moreover, the study identifies potential prospects for addressing these challenges through community engagement, health education, and policy interventions. It emphasizes the importance of fostering adaptive strategies to enhance resilience among young people in mountainous regions, ensuring their physical development is supported in the face of climate change. By implementing sustainable practices and promoting environmental awareness, communities can mitigate adverse effects and promote healthier futures for the youth. The levels of the mass-height index, Broca's index, Quetelet's index and maximum permissible mass in the mid-mountain region among girls decreased to 36.5 kg/cm, 56.0 kg, 362.5 g/cm and 51.7 kg, and on the plain they were 38.5; 62.7; 384.5 and 65.1, respectively. Among young men, at an altitude of 1600 m above sea level, there was a decrease in the values of the mass-height index, Broca's index, Quetelet's index and maximum permissible mass to 43.0 kg/cm, 62.7 kg, 429.9 g/cm and 63.1 kg, and the initial values were 44.2; 66.7; 441.5 and 78.5, respectively. The value of the vital index in low-mountain and mid-mountain conditions increased to 50.0 and 58.7 ml/kg for girls, to 60.6 and 66.3 for boys, and was 46.3 and 54.8 for control students.

Keywords: climate change, mountainous regions, body weight, vital capacity, mass-height index, Broca's index, vital index.

I. Introduction

Climate change poses one of the most significant challenges of the 21st century, impacting ecosystems, weather patterns, and human health across the globe. Mountainous regions, known for their unique biodiversity and distinct climatic conditions, are particularly vulnerable to the effects of climate change. As temperatures rise and weather patterns become increasingly unpredictable, the physical development of young people living in these areas is at risk.

Young people in mountainous regions face a myriad of environmental challenges that can adversely affect their growth and health. Factors such as increased air pollution, altered precipitation patterns leading to water scarcity, and the shifting availability of local food sources directly influence their nutrition, physical activity levels, and overall well-being. These changes can lead to an array of health issues, including respiratory illnesses, nutritional deficiencies, and reduced physical fitness. Moreover, the psychological impact of climate change, characterized by anxiety about the future and stress related to environmental instability, can further hinder the healthy development of youth.

Understanding the intricate relationship between climate change and the physical development of young people in mountainous regions is essential for developing effective interventions. This study aims to explore the multifaceted problems arising from climate change in these areas, while also identifying potential prospects for promoting resilience and adaptive strategies. By fostering community engagement and enhancing health education, stakeholders can play a vital role in addressing the challenges posed by climate change, ensuring the physical well-being and development of young people in mountainous regions.

This research not only highlights the pressing need for action but also emphasizes the importance of sustainable practices that can mitigate the effects of climate change. Ultimately, it seeks to provide insights that will contribute to healthier futures for young populations in vulnerable mountainous areas, enabling them to thrive despite the environmental challenges they face.

The physiological development of students living and studying in mountainous regions is shaped by unique environmental factors that distinguish these areas from lowland or urban settings. Mountain terrains are characterized by higher altitudes, lower atmospheric pressure, reduced oxygen levels, colder temperatures, and rugged landscapes, all of which contribute to a distinctive physical and physiological adaptation process in individuals.

This setting imposes various challenges on the human body, particularly during developmental stages such as adolescence, when the body is highly responsive to environmental conditions. Factors such as altitude-induced hypoxia (reduced oxygen supply), increased physical activity due to steep terrains, and the need for thermal regulation all play significant roles in shaping the growth, cardiovascular fitness, respiratory capacity, and overall stamina of students in these regions.

The unique demands of mountain environments stimulate specific adaptive responses, which can lead to variations in lung capacity, red blood cell production, muscular development, and metabolic efficiency compared to students living at lower altitudes. Understanding these physiological adaptations is critical for ensuring that educational and health programs are tailored to meet the needs of students in mountain regions.

This introduction sets the stage for exploring how the interplay of environmental stressors, physical activity, and altitude influences the physiological growth and health outcomes of students, highlighting both the benefits and challenges posed by mountainous terrains.

In various environmental conditions, the human body is capable of maintaining the constancy of the internal environment through adaptive responses, as well as regulating the functional activity of its systems due to the fact that it is a self-regulating and self-sustaining system.

In response to the effects of mountain hypoxia, the human body begins a process of adaptive reactions, primarily from the cardiorespiratory and nervous systems. People who are not prepared for the effects of mountain hypoxia begin to feel the negative effects of altitude at an altitude of 2500-3000 m above sea level. When healthy people climb mountains at an altitude of 4000 meters, every fifth person experiences symptoms of altitude sickness, the severity of which depends on the individual characteristics of the body. Residents living at an altitude of 4500 m experience adaptation disorders that lead to decreased performance.

Mountainous terrain above 4500 meters is uninhabited, and the conditions of this terrain have a negative impact on human health. The body's adaptive reactions disappear at an altitude of 6500-7000 meters [10].

Researchers have long established that prolonged exposure to high-altitude hypoxia is accompanied by an increase in the body's reserves and stimulation of the activity of vital body systems. At the same time, the negative impact of negative environmental factors is reduced. The process of adaptation to mountain conditions is to some extent controllable, but its effectiveness decreases at high altitudes. The number of people doing their jobs and enjoying active recreation in the mountains increases year after year. Therefore, research aimed at studying the state of human body systems and developing methods for preventing possible disruptions in their functioning in mountainous areas is relevant.

On the other hand, as the number of people living in mountainous conditions increases, the number of people exposed to the negative factors of this area increases. Therefore, determining the state of the body and its resistance to the effects of mountain conditions is of particular importance. This makes the study of the physiological development of students in mountainous areas important.

II. Methods

Laboratory equipment of the Department of Physiology and Anatomy of Humans and Animals was used to conduct the research.

The object of the study were 180 (90 girls and boys) clinically healthy full-time students. Of these, depending on the altitude of residence above sea level (Grozny - 170 m, Shatoi district - 600 m, Sharoi district - 1600 m), 3 groups were formed. Each group included thirty girls and boys. Residents of the plain were considered the control or first group, lowlanders - the second, and mid-mountains - the third.

To determine the physiological development of students, we used body weight, body length, maximum permissible weight according to B.I. Tkachenko 1994 and calculated indicators: mass-height indicator MHI = weight, kg x 100 / height, cm; body mass index BMI = weight, kg / height, m **2** ; vital index VI = VC, ml / weight, kg; Quetelet index CI = weight, g / height, cm; expected body weight according to Broca's index: for height up to 155 cm, weight = height, cm – 95; 156-165 cm, weight = height, cm – 100; 166-175 cm (height – 105); 175 and above (height – 110). The state of the respiratory system was studied using the Diamant-S spirograph.

Biometric control of experimental data was carried out using the Biostatistics program, comparison of average indicators of groups using the Student's criterion.

IV. Discussion

The weight, height and VC of students in the mountains are given in Tables 1-2 and Figures 1-2. From these tables and figures it is evident that in mountain conditions there is a statistically significant change in the weight, body length and VC of students.

Thus, the body length of girls and boys in the third group is 12.7 (P < 0.01) and 13.3 cm (P < 0.02) lower than the initial values.

Table 1: *Physical development indicators and vital capacity of lungs of girls*

Terrain	Height in cm	Body weight in kg	YELLOW in L
Plain	164.7±3.49	63.3±1.38	2.93±0.061
Lowlands	158.6±3.12	61.7±1.53	3.08±0.062
Middle Mountains	152.0±1.86***	55.1±0.83****	3.23±0.041***

*** – P < 0.01; **** – P < 0.001

The body weight of girls and boys living in mid-mountain conditions decreased by 8.2 (P < 0.001) and 7.8 kg (P < 0.01) compared to the values of lowland residents.

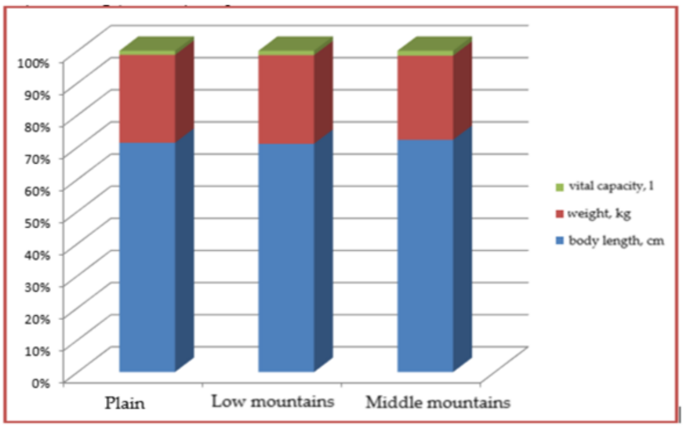

Figure 1: Height, weight and vital capacity of female students under hypoxic conditions

Our results are confirmed by other researchers. Thus, the distinctive features of mountain dwellers are short stature and reduced body weight [12]. Long-term residence in conditions of mountain hypoxia is accompanied by a decrease in body length and weight by an average of 13.5 cm and 9 kg [12]. Living in the highlands reduces a person's height and weight by 17.7 cm and 15.3 kg compared to lowland residents [11, 13, 8].

Most populations of people of different racial and ethnic origins living in mountainous areas are characterized by slow growth processes and large body sizes [2]. Due to the low body volume, highlanders consume less oxygen [5].

Exposure to mid-mountain conditions increased the level of vital capacity in girls by 0.30 l ($P < 0.01$) and in boys by 0.37 l ($P < 0.02$) relative to the values of the control groups.

People living in conditions of high-altitude hypoxia have a high number of respiratory movements per minute, high lung ventilation and lung capacity, as well as large respiratory volumes of the lungs [15].

Table 2: *Height, weight and vital capacity of young men*

Terrain	Height in cm	Body weight in kg	YELLOW in L
Plain	173.7±2.90	76.7±1.26	4.20±0.072
Lowlands	167.6±3.68	72.5±1.69	4.39±4.39±0.095
Middle Mountains	160.4±3.63**	68.9±1.39***	4.57±0.103**

** – $P < 0.02$; *** – $P < 0.01$

Aidaraliev A.A. [3] concluded from the results of his research that an increase in respiratory volume is the cause of increased lung ventilation in humans when exposed to hypoxia.

According to B. Messerli and J.D. Ives [7], as well as O.G. Gazenko [16], mountain dwellers have a large chest, high vital capacity and a high level of oxygen in the blood. At the beginning of the process of human adaptation to conditions of oxygen deficiency in the inhaled air, an increase in the amount of alveolar ventilation occurs [6]. An increase in the depth of breathing and ventilation of the lungs is the human body's response to the effects of insufficient oxygen content in the environment [14]. Apparently, exposure to high-altitude hypoxia causes an increase in the vital capacity of the lungs in students due to an increase in the tone of the inspiratory muscles.

Thus, due to the high tone of the inspiratory muscles, the vital capacity in conditions of high-altitude hypoxia is 10% greater [1]. Probably, due to the stimulation of the respiratory center by the oxygen deficiency, the strengthening of the respiratory system function is caused. When a person adapts to conditions of mountain hypoxia, the functional activity of the systems that supply the body with oxygen increases [9].

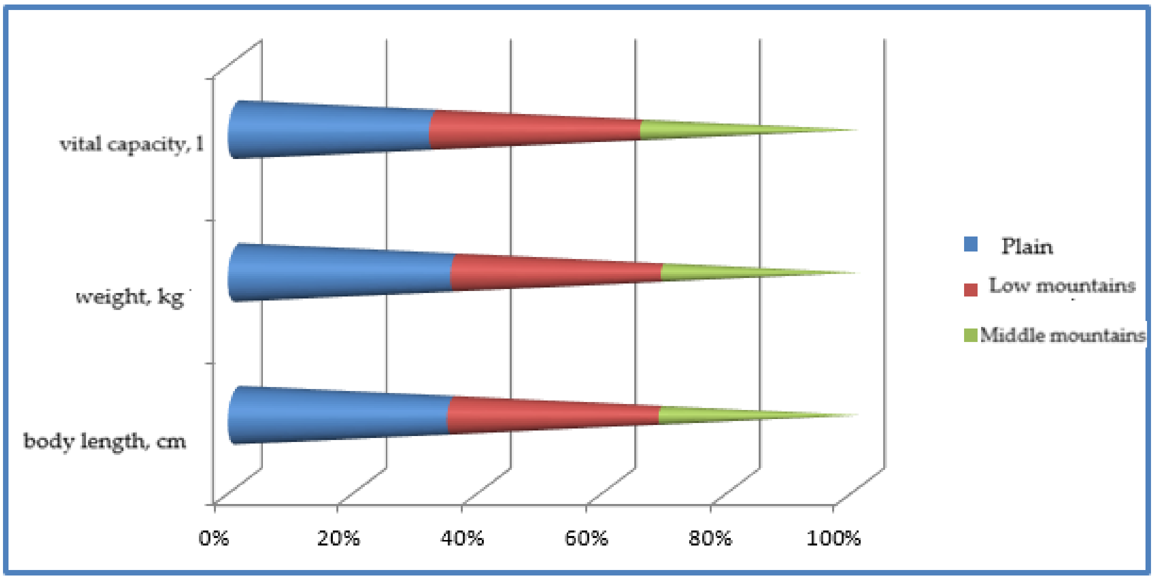

Figure 2: *Weight, height and vital capacity of young men under hypoxia*

Increased pulmonary ventilation and a reduction in the time of hemoglobin oxygen saturation are caused by low oxygen content in the external environment [4]. When exposed to hypoxia, statistically significant changes occur in the physiological development indicators of students, with the exception of body mass index (Table 3-4 and Fig. 3-4).

Thus, the value of the mass-height indicator in girls and boys in mid-mountain conditions is lower by 2.0 (P < 0.001) and 1.2 kg/cm (P < 0.05) relative to the initial level.

Table 3: *Indicators of physiological development of girls in conditions of mountain hypoxia*

Indicators	Altitude above sea level in meters		
	170	600	1600
Weight-height index, kg/cm	38.5±0.23	38.9±0.49	36.5±0.37****
Body mass index, kg/ m2	23.4±0.54	24.6±0.51	23.9±0.39
Broca's index, kg	62.7±1.72	59.1±1.84	56.0±1.05***
Vital index, ml/kg	46.3±0.28	50.0±0.66****	58.7±0.62****
Quetelet index, g/cm	384.5±2.30	388.8±4.86	362.5±3.67****
Maximum permissible weight, kg	65.1±3.72	58.5±3.18	51.7±1.91***

*** – P < 0.01; **** – P < 0.001

The MCI value of girls in the conditions of the plain and low mountains (38.5 and 38.9 kg/cm) indicates a normal ratio of body length and weight, and in the mid-mountain (36.5) - low nutrition. The level of MCI in the groups of boys shows their increased fatness.

The level of the Quetelet index in groups of men indicates the presence of excess weight. The decrease in the maximum permissible weight in girls and boys in the midlands was 13.4 (P < 0.01) and 15.4 kg (P < 0.02) relative to the values of the control students.

The maximum permissible weight for the group of girls in plain conditions is 1.8 kg higher than the actual weight, and for the second and third groups it is 3.2 and 3.4 kg lower, respectively. The actual weight of the boys in the first group is 1.8 kg lower than the maximum permissible weight, and in low-mountain and mid-mountain conditions it is 2.2 and 5.8 kg higher.

Thus, mountain hypoxia causes a reliable decrease in the level of mass-height index, Broca's index, Quetelet index, maximum permissible mass and a statistically significant increase in the vital index in students.

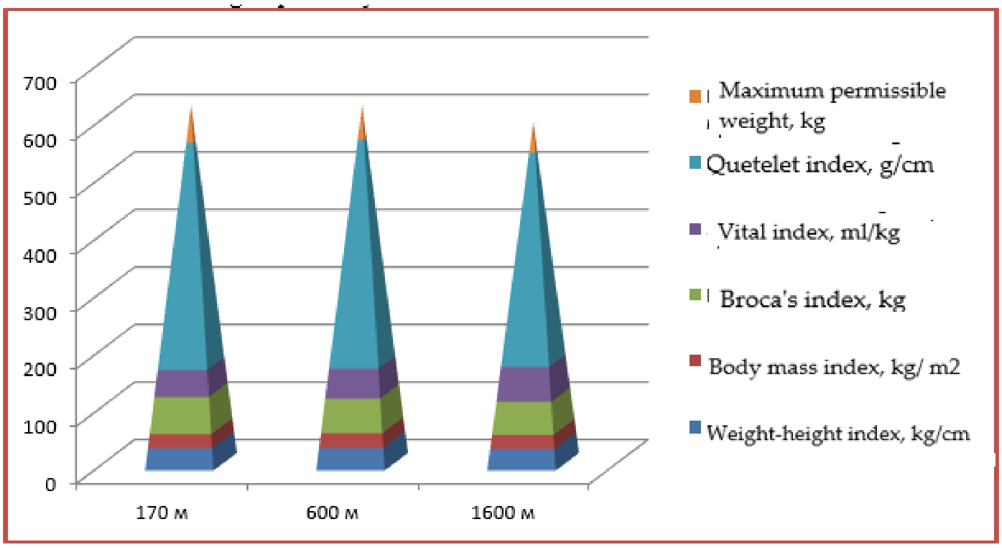

Figure 3: *The impact of hypoxia on physiological development indicators of female students*

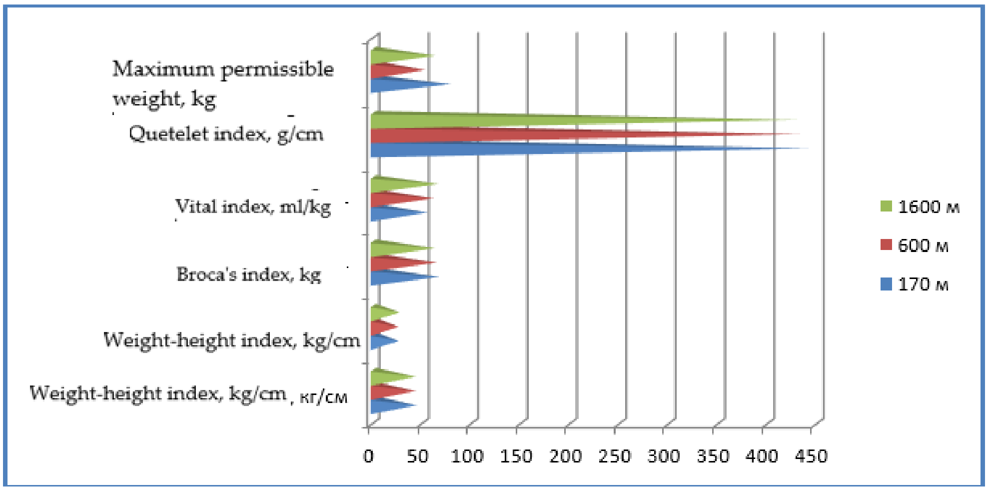

Figure 4: *The influence of mountain hypoxia on the physiological development of young men*

In girls and boys living in mid-mountain conditions, body height is 7.8 ($P < 0.01$) and 7.7% ($P < 0.02$) lower, and weight is 13.0 ($P < 0.001$) and 10.2% ($P < 0.01$) lower than in lowland residents.

At an altitude of 1600 m, the level of vital capacity in girls is 10.2% higher, and in boys it is 8.8% higher compared to the values of students in the control groups. Under conditions of high-altitude hypoxia, statistically significant changes occur in the values of the MRP, Broca's index, GI, IC, and the maximum permissible weight of students. The mass-height index of girls and their peers living in the mid-mountain regions is lower by 5.2 ($P < 0.001$) and 2.7% ($P < 0.05$) compared to the values of the first groups. In the mid-mountain region, the Broca index is 10.7% lower ($P < 0.01$) among girls, and 6.0 lower among boys relative to the baseline values. The level of vital index in girls and boys in the low mountains increased by 8.0 ($P < 0.001$) and 10.6% ($P < 0.001$), and in the mid-mountain regions by 26.8 ($P < 0.001$) and 21.0 ($P < 0.001$) compared to the values of students in the control groups. The Quetelet index value in mid-mountain conditions decreased by 5.7% ($P < 0.001$) among girls and by 2.6% ($P < 0.05$) among boys relative to the level of those living on the plain. The maximum allowable weight of girls and boys living in the mid-mountain areas decreased by 20.6 ($P < 0.01$) and 19.6% ($P < 0.02$) compared to the initial values.

The impact of climate change on the physical development of young people in mountainous regions is a complex interplay of environmental, social, and health factors. As this study outlines, the physiological effects of changing climate patterns can manifest in various ways, influencing the overall well-being and growth trajectories of youth. Understanding these interconnections is crucial for developing targeted interventions and policies.

One of the most immediate consequences of climate change in mountainous areas is the deterioration of air quality due to increased pollution and wildfires, leading to respiratory diseases. Young people, whose lungs and immune systems are still developing, are particularly vulnerable. Research has shown that children and adolescents living in areas with poor air quality experience higher rates of asthma and other respiratory illnesses. Additionally, changes in temperature and precipitation can exacerbate these conditions, leading to a cycle of health issues that further hinders physical development.

Nutritional status is another critical area impacted by climate change. As agricultural patterns shift due to changing climatic conditions, the availability of local food sources may decline, leading to food insecurity and poor nutritional outcomes. In mountainous regions, where access to diverse food options is already limited, these changes can result in higher rates of malnutrition among young people. Poor nutrition during critical growth periods can have long-lasting effects on physical development, including stunted growth, weakened immune systems, and cognitive impairments.

The psychological impacts of climate change should not be overlooked. Young people in mountainous regions may experience heightened anxiety and stress due to environmental changes, including natural disasters, loss of familiar landscapes, and uncertainty about the future. These psychological factors can contribute to mental health issues, which may further impede physical development. Creating supportive environments where young people can express their concerns and seek help is essential for addressing these challenges.

Addressing the impact of climate change on the physical development of young people requires comprehensive community engagement and policy interventions. Schools and local governments can play a crucial role by integrating climate education into curricula, raising awareness about the health implications of climate change, and promoting sustainable practices.

Programs that encourage physical activity in nature can help mitigate some of the health risks associated with climate change while promoting mental well-being. Initiatives that support local agriculture and food security can also improve nutrition, ensuring that young people have access to healthy foods that are essential for their growth and development.

Additionally, mental health support systems should be established to assist young people in coping with the stressors associated with climate change. This can include counseling services, community workshops, and youth-led initiatives aimed at fostering resilience and promoting mental health.

Further research is essential to deepen our understanding of the long-term effects of climate change on the physical development of young people in mountainous regions. Longitudinal studies can provide valuable insights into how changing climate patterns influence growth and health over time. Investigating the effectiveness of specific interventions aimed at mitigating these impacts will also be crucial for informing future policies and practices.

In conclusion, the physical development of young people in mountainous regions is intricately linked to the challenges posed by climate change. By recognizing the multifaceted nature of this issue, stakeholders can develop targeted strategies that address health implications, promote resilience, and support sustainable practices. Ensuring the well-being of young populations in vulnerable areas is not only vital for their individual health but also for the broader goal of fostering sustainable and healthy communities in the face of climate change.

Abstract

The Chechen Republic has one of the highest levels of biological diversity, due to the unique natural conditions and the presence of various high-altitude zones, ranging from semi-deserts to glaciers. This diversity includes animals from Europe, Asia, Siberia, and even Africa, making it a fascinating place to explore. However, the biological diversity in the region is still poorly understood. The vertebrate fauna in the Chechen Republic includes 44 fish species and subspecies, nine amphibian species, at least 31 reptile species, more than 320 bird species that nest, and up to 88 mammal species. Unfortunately, this rich ecosystem is threatened by the devastating effects of war, which have led to uncontrolled and intensive exploitation of natural resources. As a result, preserving the biodiversity of the area is a significant challenge. Many areas have changed, losing their original appearance. The environmental conditions for many animal species have deteriorated, leading to fewer of them. Some species, such as bison, moose, tarpans, kulans, and beavers have completely disappeared, while others, like the common grouse and geese, are becoming rare. Bezoar goats, chamois, martens, otters, minks, bustards, strepets, cranes, grey partridges and ulars have become few. Taking into account the current ecological situation in the republic and to preserve the unique fauna and flora, it is essential to take measures to conserve and increase the biodiversity of the landscapes.

Keywords: biological diversity, protected areas, natural framework

I. Introduction

The development of STR (Scientific and Technical Revolution) is accompanied by an increase in the level of economic development, which inevitably leads to a decrease in biodiversity and a reduction in species. If these processes exclude each other, then saving biodiversity both of living organisms and ecosystems becomes the most difficult task. In that case, it is necessary to think about conservation of biodiversity as an integral part of sustainable development rather than just as a part of nature conservation. In this context, a special role belongs to the creation and development of special educational systems for protected natural areas. This is one of the main directions in the work of state environmental organizations. Specially protected territories are part of our national heritage, and their conservation and protection is essential [1]. The protection regime of specially protected natural territories and the status of environmental institutions located within them differ in several categories. All of these territories form a state-owned nature reserve fund, which is under the jurisdiction and management of a specially authorized state body in the field of environmental protection.

II. Methods

We live in a time of many global challenges that can only be addressed through the combined efforts of all nations. Not even the most developed countries can solve these challenges on their own, as they affect everyone and require a collaborative approach to overcome.

The issue of preserving biodiversity has reached a point where it is a concern not only for those who study biological systems, but also for scientists, economists, politicians, and the general public [2].

For countries seeking to conserve and enhance the variety of biological resources, policies should be guided by addressing environmental challenges, which in turn will facilitate sustainable economic growth.

Turning to the term "diversity", it refers to differences between groups of entities and phenomena, and the extent of these variations can be quite varied. Biological diversity, in particular, pertains to the variety of living organisms, making "biological diversity" and "biodiversity" synonymous terms [3].

As it is known, the advancement of STR (Scientific and Technical Revolution) is accompanied by an upsurge in economic development levels, which in turn inevitably leads to a decline in biodiversity and reduction in species numbers. If these trends are mutually exclusive, the preservation of biodiversity for both living organisms and ecosystems becomes a challenging and difficult endeavor. In such a scenario, it becomes necessary to conceive of biodiversity conservation not as a component of environmental protection but rather as an integral aspect of the sustainable development paradigm.

The 1992 Convention on Biological Diversity, held in Rio de Janeiro, was a significant event in this regard. The Convention was intended to serve as a foundation for environmental research and the practical application of the findings of these studies. Two key concepts were emphasized in the Convention: preservation and utilization. This meant conserving and sustainably utilizing biodiversity. The term "sustainable utilization" used in the Convention referred to the idea that the rate and extent of utilization should not lead to the depletion of biodiversity. Thus, the Convention upheld the principle of protecting biodiversity through responsible use. It was acknowledged that the solution to biodiversity loss lies in collaborative efforts to conserve and restore biodiversity[4].

The global environmental issue is no longer solely related to the threat of biodiversity, but also to the impact on human health. Catastrophic oil spills and forest fires affecting tens of thousands of hectares, as well as imperceptible, but threatening forms of pollution, often occur in nature. Their effects may not be immediately apparent, but they can manifest themselves after some time and be unexpected [5].

An integrated approach to protecting and preserving what humanity has involves a resolute system of rules and penalties as well as an environmental monitoring service. The concept of "environmental ethics" is now in use and is a rapidly developing new area of philosophy that vividly illustrates the high ethical value of nature.

Following the principles of environmental ethics can help to preserve natural and biological diversity, which should become a fundamental and priority direction for the development of both the state and society. As a result of complying with these principles, there will be a steady decrease in production and consumption levels, leading to a more sustainable approach to resource extraction and consumption [6]. Additionally, there will be an expansion of protected natural areas, helping to ensure the long-term survival of biodiversity.

III. Results

There are several arguments in favor of the ethics of biodiversity conservation, regardless of the economic value of each species. In this context, all species contribute to the overall goal of survival. It is important to consider the diversity of species, rather than focusing on their numerical value, geographical location, age, or economic importance. Each species has a unique role in the natural and human world, and their extinction can have a significant impact on other species and ecosystems. This connection between all living things is essential for maintaining balance and harmony in nature [7,8].

In Russia, biodiversity conservation efforts began with the signing of Decree No. 236 by the President of the Russian Federation on February 4, 1994, titled "On the State Strategy of Environmental Protection and Sustainable Development in the Russian Federation".

In 2001, the National Strategy for the Conservation of Biodiversity in Russia was developed. This strategy highlighted the main directions and principles and set priorities for the long-term conservation of biological diversity in Russia.

The leading principles of this strategy included the following:

1) preservation of genotypes and reproductive capacity;
2) maintenance of population numbers and habitats;
3) protection of species and their natural habitats;
4) restoration and preservation of biocenoses;
5) preservation of natural ecosystems;
6) protection of natural complex territories;
7) conservation of the species composition of the biosphere as a whole.

But the preservation of biodiversity on the planet is a challenge that can only be addressed through the efforts of all nations. This issue is comparable to other global challenges that humanity has faced. We must recognize that this is not simply a matter of protecting nature, but rather a fundamental shift towards a more sustainable development model [9].

In its importance, this issue is of international concern and the solution to biodiversity problems lies in each country fulfilling its obligations. To this end, national legislation must be aligned with international standards.

Addressing biodiversity issues is crucial not only for the environment but also for human wellbeing. Surprisingly, conservation of biodiversity has been shown to be a leading factor in reducing poverty. As most people in underdeveloped countries live in rural areas, addressing biodiversity conservation issues would allow them to secure food and income.

The population of the Earth, depending on their place of residence, are oriented towards certain sources of livelihood. More than 3 billion people feed and live at the expense of marine and coastal areas. For 1.6 billion, forests and forest products are the source of livelihood, and the loss of biodiversity threatens the well-being of over 1 billion humans living in arid and semi–arid areas.

IV. Discussion

Summing up, biodiversity, its conservation, and protection are essential for the normal function of ecosystems and human well–being. This applies not only to economic development but also to health, food security, water supplies, and disaster prevention.

The steady growth of the world's population and, as a result, the proportional increase in its needs, which can be met by expanding industrial and agricultural production and developing transport, creates increased anthropogenic pressure on the environment.

The Law of the Chechen Republic No.10-RL (Russian Law) on Environmental Protection of July 4, 2006 with amendments regulates relations in the “nature-society” system in order to maintain dynamic balance.

Based on this, it follows that efforts must be made in order to create a natural ecological framework in the territory of the Republic to create conditions for sustainable development and conservation of landscapes and biological diversity.

To fully understand the role of natural and ecological systems, it is important to consider not only specially protected areas, but also other features such as forest belts, parks, green zones, and water protection areas. These additions to the protected framework will help reduce human impact on natural landscapes and ecosystems [10].

Additionally, it is essential to create areas where nature management can be approached with reference to cultural and historical traditions. This approach can help ensure a more gentle approach to environmental management, using traditional methods that have been proven effective over time. Finally, including disturbed lands within the natural and ecological system is crucial for maintaining balance and sustainability [11].

However, all these measures and proposals need to be supported by financial resources in order to ensure that they are implemented. Therefore, it is essential that all measures related to specially protected areas are included in the socio-economic development plans of the republic, as well as in the territorial schemes and district planning schemes, and in all forest management plans.

Another important condition for the use of SPNT (specially protected natural territories) is that it is possible only with the permission of relevant authorities in the field of environmental protection.

In this regard, we cannot ignore the "Red Book of the Chechen Republic", which was first published in 2007. Although the purposeful study of flora and fauna in the Chechen Republic has been going on for much longer, the Red Book summarizes a list of rare and endangered plant and animal species that require special protection.

It is a great responsibility for the Directorate of Specially Protected Natural Territories in the Chechen Republic to preserve and protect endangered plant and animal species listed in the "Red Book". The Directorate is responsible for implementing special protection measures for protected areas in order to ensure their survival. The Directorate should strengthen the special protection regime and monitor the functioning and management of protected areas to ensure that they are properly protected [12].

It is also important to pay attention to the lack of warning and signage along the perimeter and boundaries of protected areas, as well as to organize proper records of owners, landowners, and users in order to establish clear responsibility for compliance with special protection regulations.

The task of ensuring proper control over specially protected natural areas is a challenging one, but it is essential for the conservation and restoration of biodiversity. This task begins at the local level and extends to the level of administrative and municipal authorities.

Acknowledgments

The work was carried out within the framework of the state assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 075-03-2021- 074 / 4).

SEASONAL CLIMATE CHANGES AND THEIR IMPACT ON FEMALE STUDENTS' IMMUNITY: RELATIONSHIP WITH THE CONCEPT OF SUSTAINABLE DEVELOPMENT

Vakha Anzorov, Svetlana Moryakina
•
Kadyrov Chechen State University, RUSSIA
vaha-anzorov@mail.ru

Abstract

This study explores the impact of seasonal climate changes on the immunity of female students, highlighting the intricate relationship between environmental factors and health. Seasonal fluctuations, including temperature variations, humidity levels, and air quality changes, can significantly influence immune system responses. The research examines how these climatic factors affect the health and academic performance of female students, particularly in terms of increased susceptibility to illnesses during certain seasons. Moreover, the study emphasizes the importance of sustainable development in addressing these challenges. By promoting environmentally friendly practices and raising awareness about the impact of climate change on health, educational institutions can create supportive environments that enhance student resilience and well-being. The findings underscore the necessity of implementing health education programs focused on nutrition, physical activity, and stress management tailored to seasonal variations. Ultimately, this research advocates for a holistic approach that integrates health promotion with sustainable development strategies, aiming to improve the quality of life for female students in the context of a changing climate. The work is devoted to the study of the state of the health coefficient of female students in different seasons of the year. The conducted studies show that statistically significant changes in the blood pressure and health coefficient of girls are subject to seasonal changes. Thus, the level of SBP in girls increased to 127.5 mm Hg in winter, and was 113.4 in summer. The value of diastolic pressure in winter increased to 81.2 mm Hg, and the initial value was 74.5. The value of the health coefficient is maximum in winter - 1.83 and minimum in summer - 1.59. The heart rate in winter increased to 81.4 beats per minute, and in the control girls it was 77.2.

Keywords: Seasonal climate changes, season of the year, body weight, heart rate, blood pressure, health coefficient

I. Introduction

Seasonal climate changes have profound effects on various aspects of human health, including the immune system's functionality. For female students, who often juggle academic responsibilities, social engagements, and personal challenges, these seasonal fluctuations can pose significant health risks. Research indicates that variations in temperature, humidity, and air quality can lead to increased susceptibility to infections, allergies, and stress-related illnesses, all of which may adversely impact academic performance and overall well-being.

In recent years, the connection between environmental factors and health has gained increased attention, particularly in the context of sustainable development. The concept of sustainable development emphasizes the need for environmentally conscious practices that not only protect natural ecosystems but also promote the health and well-being of communities. As the climate continues to change, it becomes imperative to understand how these alterations affect specific populations, particularly vulnerable groups such as students.

This study aims to explore the intricate relationship between seasonal climate changes and the immunity of female students. It seeks to identify the specific ways in which environmental factors influence their health and to emphasize the importance of integrating health education and sustainable practices into academic settings. By understanding these dynamics, educational institutions can develop effective strategies to enhance the resilience and well-being of female students, ensuring they thrive academically and personally despite the challenges posed by a changing climate.

Considering that the health of an organism is determined by its adaptive capabilities, health is the process of adaptation of an organism to the environment [1]. A prerequisite for the successful functioning of the body is the assimilation of the rhythm set by nature. Due to the high level of coherence of cells, tissues, organs and body systems, the human body is often compared to a symphony orchestra. Biological rhythms caused by the rotation of the Earth around the Sun play an important role in the lives of humans and animals. Seasonal rhythms are considered to be seasons of the year that have different climatic conditions.

Rhythms with an annual period are the vegetation cover of the Earth, the migration of birds, the winter hibernation of animals and the activity of the reproductive system. The change of seasons is caused by the cycle of the year. The length of daylight causes the seasonal cycles of the plant and animal world.

The rhythmicity of biological processes is an inseparable property of living matter. The vital activity of plant and animal organisms occurs in rhythmically changing environmental conditions.

The process of adaptation to seasonal conditions of flora and fauna is aimed at creating optimal conditions for their vital activity. Various natural factors that affect a person and to which he adapts determine his health, well-being, activity, etc. Affecting all organs and systems of the human body, seasonal biorhythms change its performance and health. Accordingly, due to the adaptation of organisms to changing living conditions, biorhythms determine their survival. Different climate zones are characterized by different weather conditions. The reflection of various physiological processes in the human body occurs due to the presence of more than 100 biological rhythms.

Thanks to the biological clock, various rhythms of physiological processes are established. The complex of periodic changes called biorhythm is an amazing feature of the human body. Thus, biorhythm is a periodic change in the activity of the body's functional processes. The individual characteristics of the human body and the effectiveness of its mechanisms of adaptation to seasonal conditions determine its ability to withstand the impact of environmental factors.

The seasonal rhythms of each region are based on its climate. Thus, the features of the winter season of the year are an increase in the basal metabolism and fat metabolism, an increase in lung ventilation and irritability of the sympathetic branch of the autonomic nervous system.

In the summer season, the direction of changes occurring in the body is opposite.

Ukhtomsky A.A. believes that the time it takes for biological rhythms to be assimilated is individual for each person. Alternating increases and decreases in functional activity is more effective and economical than maintaining an average intensity for each organism. Achieving the highest possible human efficiency is only possible during the period of maximum activity.

The functional activity of the human body systems is high in the summer and low in the winter. The fact that a person works all year round requires him to maintain high activity of the body systems in the winter season.

Changes in biorhythms are a strong stress even for healthy people. In this connection, stimulation of the process of adaptation to living conditions must be carried out taking into account the peculiarities of human biorhythms. If a person stops following the call of nature, then disturbances from the biorhythm system occur in a short time.

Currently, the interest of doctors and physiologists in seasonal changes has grown significantly [21, 15, 22]. The study of biological rhythms allows us to determine the state of physiological functions, adaptive reserves and the body's immune system.

In recent years, much attention has been paid to the practical use of biorhythms.

The importance of studies devoted to seasonal changes is that in order to assess the normal indicators of body systems, it is necessary to take into account their seasonal characteristics.

Thus, the basis of treatment for many diseases is the restoration of the normal rhythm of the heart, lungs, stomach, intestines and central nervous system.

Taking into account the characteristics of circadian rhythms, the accuracy of diagnosis and the effectiveness of therapeutic interventions will be higher.

The body's mastery of the laws of biological rhythms allows it to maintain high performance and health.

Therefore, research aimed at determining the state of health coefficient of female students is relevant.

II. Methods

The research was conducted in the laboratories of the Department of Physiology and Anatomy of Humans and Animals. The respondents of the research were 35 clinically healthy female students of the biology and chemistry faculty of the full-time form of study. The summer season indicators were considered as control. The readings were made in a state of rest in the middle month of each season. The calculation of the health coefficient was made according to the formula:

KZ = 0.01 × HR + 0.01 SBP + 0.008 DBP + 0.014 V + 0.009 MT + 0.004 Sex (m-1, f-2) - 0.009 P - 0.273

where:

HR – heart rate in beats per minute;

SBP and DBP – systolic and diastolic blood pressure in mmHg;

A – age in years;

BM – body weight in kg;

H – height in centimeters

To determine the heart rate, systolic blood pressure and diastolic blood pressure, an automatic tonometer OMRON was used M 3 Expert.

For statistical processing of the research results, the Biostatistics program was used, and for comparison of the average indicators of the groups, the Student's criterion was used.

Seasonal features of anthropometric indicators are given in Table 1 and Figure 1.

Table 1: The influence of the season on the physical development of girls

Season of the year	Indicators		
	Height in cm	Weight in kg	Age in years
Summer	162.6 ± 2.95	61.1 ± 1.20	18.9 ± 0.13
Autumn	165.0 ± 2.49	62.5 ± 0.97	19.2 ± 0.15
Winter	166.1 ± 2.81	64.1 ± 1.08	19.5 ± 0.16
Spring	162.8 ± 2.91	61.3 ± 1.28	19.8 ± 0.22

There are no reliable changes in the height and weight of girls by seasons, however, their level is higher in winter and lower in summer. Thus, the body length higher in winter by 3.5 cm compared to the summer level.

The increase in body weight in the group in winter was 3.0 kg compared to the initial value. The difference in age between the mean values of the groups was 0.9 years.

Other researchers have also come to similar results in their studies. Thus, body weight increases by up to 5% in autumn and winter [5]. Throughout the year, body weight is at its maximum in winter and minimum in summer, which is explained by high physical activity in summer and low in winter [8]. The increase in body weight of each person in autumn and winter conditions ranges from 2 to 5 kg, which occurs due to the reduction in daylight hours, leading to overeating, as well as a slowdown in the metabolic process [9]. In studies conducted by Japanese scientists on elementary school children, it was found that their weight increases in autumn and winter and decreases in summer [3].

According to the results of research by American scientists, it has been established that the growth rate of children is higher in the autumn-winter season of the year, compared to the level of spring-summer [7]. Factors such as the accumulation of fatty tissue, changes in diet, reduction in the duration of daylight hours, a decrease in ambient temperature and increased stress cause an increase in body weight in the autumn and winter [5].

IV. Discussion

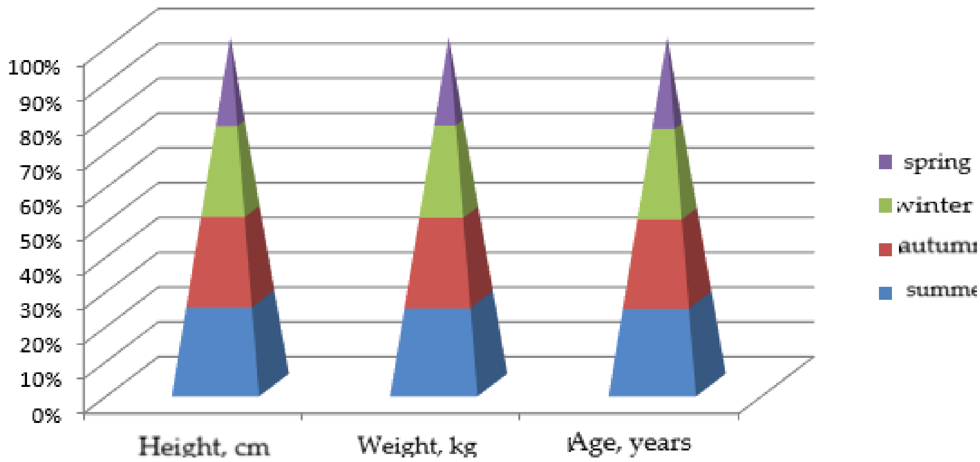

Figure 1: *Seasonal features of anthropometric indicators of girls*

The reasons for changes in body weight by season are activity and nutrition [4] . For example, an increase in physical activity and energy use in the summer reduces body weight, while a decrease in the winter, on the contrary, increases it [4]. In autumn and winter, the production of the hormone melatonin by the pineal gland increases, which increases drowsiness and appetite [4].

Scientists claim that the greatest growth rate of schoolchildren occurs in the first half of the year [3]. Scientists believe that cold climates contribute to increased height and weight, and that large bodies are better able to tolerate low ambient temperatures [10].

Table 2: *Seasonal features of some indicators of the cardiovascular system and health coefficient of girls*

	Indicators			
Season of the year	Heart rate in beats per minute	SBP in mmHg	DBP in mmHg	Health coefficient
Summer	77.2±1.61	113.4±2.28	74.5±1.56	1.59±0.053
Autumn	80.0±1.69	119.2±2.77	77.9±1.62	1.70±0.062
Winter	81.4±1.88	127.5±2.84***	81.2±1.78**	1.83±0.066**
Spring	80.3±1.58	120.5±1.96*	80.1±1.57*	1.75±0.042*

* – P < 0.05; ** – P < 0.02; *** – P < 0.01

Some indicators of the cardiovascular system and the health coefficient of girls in different seasons of the year are given in Table 2 and Figure 2. It follows from them that the season of the year has a statistically significant effect on SBP, DBP and the health coefficient.

Thus, the level of systolic blood pressure in girls in the winter and spring seasons of the year is higher by 14.1 ($P < 0.01$) and 7.1 mm Hg ($P < 0.05$) relative to the value in the summer period of the year.

The diastolic blood pressure value of girls in winter and spring increased by 6.7 ($P < 0.02$) and 5.6 mmHg ($P < 0.05$) compared to the level of control girls. The heart rate of girls in winter is 4.2 beats per minute faster compared to the value of girls in the control group. Our results are confirmed by other scientists. Thus, blood pressure is subject to seasonal changes [26, 17]. According to a number of authors, its value is higher in winter than in summer [90, 13, 69, 16, 18].

According to K.J. Radke and J.L. Jr. Izzo [24], the heart rate increases by 5% in winter.

Apparently, high levels of adrenaline and noradrenaline in the blood in winter increase heart rate, systolic blood pressure and diastolic blood pressure, while low levels in summer decrease them.

Our findings are confirmed by other authors. Thus, from the analysis of the results of studies by various authors, it can be concluded that the causes of seasonal fluctuations in HR, SBP and DBP are seasonal changes in the production of catecholamine hormones, temperature and day length [14, 23, 25, 27].

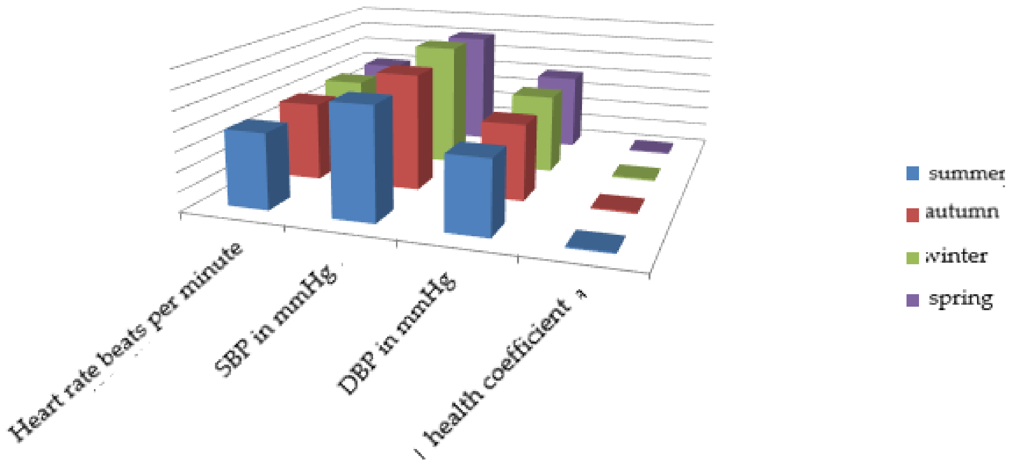

Figure 2: *The influence of the season on the level of heart rate, systolic blood pressure, diastolic blood pressure and the health coefficient of girls*

In winter, the concentration of catecholamines in the blood increases, and in summer it decreases [27].

Also, factors that increase blood pressure include low temperatures in the external environment, short daylight hours, narrowing of blood vessels and high sweating [23, 14, 25, 20, 12].

The level of the health coefficient of girls in winter and spring is higher by 0.24 ($P < 0.02$) and 0.16 ($P < 0.05$) relative to the initial value. The state of the health coefficient of girls in all seasons of the year indicates a satisfactory level of their health. With the increase of the value of the health coefficient of students, there is a decrease in their health level. A high level of health among girls is revealed in the summer period of the year, and a low one - in the winter season of the year.

Apparently, the improvement of girls' health in summer occurs due to a decrease in the intensity of metabolism, the prevalence of anabolism processes, an increase in the motor regime, an increase in the duration of daylight hours and the ambient temperature. Similar conclusions were reached in their studies [8, 9, 5, 4, 10] .

Analysis of the results of the studies by A.A. Artemenko [2] and E.A. Shtrikh [11] indicate that modern students are characterized by physical inactivity, poor physical fitness, and poor health. According to V.D. Sonkin and others [22], students have low physical fitness and poor health. Thus, in the spring and winter seasons of the year, there is a reliable increase in the level of SBP, DBP and the health coefficient of female students.

The length and weight of girls' bodies do not undergo statistically significant changes across seasons. In winter, there is a 2.2% increase in body length and a 4.9% increase in weight compared to summer levels. The value is 10.3% higher in spring ($P < 0.05$) and 12.4% higher in winter ($P < 0.01$) relative to the control group value. The increase in the DBP value in spring was 7.5% ($P < 0.05$), and in winter – 9.0% ($P < 0.02$) compared to the value for the summer season. The increase in the health coefficient of girls in the spring season was 10.1% ($P < 0.05$), and in winter – 15.1% ($P < 0.02$) relative to the level of control girls. The heart rate level in winter is 5.4% higher than the baseline value.

The interplay between seasonal climate changes and the immune system of female students is a multifaceted issue that warrants thorough exploration. As this study indicates, fluctuations in weather conditions can significantly affect the health of this demographic, making them more susceptible to infections and illnesses. For instance, during colder months, lower temperatures and increased indoor crowding can facilitate the spread of respiratory viruses, while warmer months may bring about allergens like pollen, contributing to respiratory issues and allergies.

The heightened vulnerability of female students to seasonal illnesses not only affects their physical health but also their mental well-being. Stress and anxiety related to health concerns can detract from their academic focus and overall quality of life. Therefore, understanding the specific health implications of seasonal climate changes is crucial. Educational institutions should consider implementing preventive health measures, such as vaccination programs and awareness campaigns about seasonal illnesses, to safeguard students' health.

The link between these health challenges and sustainable development is particularly pertinent. Sustainable development emphasizes the importance of a healthy population in fostering economic growth and social equity. By addressing the environmental factors that contribute to seasonal health issues, universities can play a pivotal role in promoting sustainable practices. For example, initiatives aimed at improving campus air quality, enhancing green spaces, and encouraging sustainable transportation can mitigate some of the adverse health impacts associated with climate change.

A holistic approach is necessary to effectively address these issues. This involves not only raising awareness about the effects of seasonal climate changes but also integrating health education into academic curricula. Programs focusing on nutrition, physical activity, and stress management can empower female students to take charge of their health, equipping them with the tools to build resilience against seasonal health challenges.

Further research is essential to understand the long-term effects of seasonal climate changes on the immune health of female students. Longitudinal studies could provide insights into how these changes influence health over time and inform targeted interventions. Additionally, research exploring the effectiveness of specific health education programs in mitigating seasonal health risks can help develop best practices that educational institutions can adopt.

In conclusion, the impact of seasonal climate changes on the immunity of female students presents significant challenges that intersect with the goals of sustainable development. By recognizing the health implications of these environmental factors and implementing strategic interventions, educational institutions can foster healthier and more resilient student populations. A proactive approach will not only enhance the well-being of female students but also contribute to broader efforts toward sustainable development and community health.

Abstract

The paper attempts to consider geological processes occurring in the upper layers of the Earth, which either simplify or complicate the native relief. In this case, the territory subject to exogenous processes is likened to a nonequilibrium, open thermodynamic system. For successful application of the synergetic approach to natural phenomena, a comprehensive study of the degree of influence of each of the factors acting on the system under consideration on the processes occurring in it is required. Therefore, this paper focuses on the dynamics of the development of exogenous processes in the south-eastern part of the Chechen Republic, subject to exogenous processes. It is shown that these processes are cyclical in nature and cause great harm to the economy and population of the region. Geodynamic processes arising during long-term development of oil and gas fields are also considered. This work can be considered as a preparatory stage for the study of these phenomena based on the synergetic approach. It is expected that these studies can become the basis for systematization, theoretical generalization of the results obtained and the development of methods for predicting natural processes.

Keywords: landslide processes, geological risks, slope erosion

I. Introduction

In recent years, many scientific fields have often used a synergetic approach, which takes into account the collective action of a number of factors on a nonequilibrium system. The essence of the synergetic paradigm is the presence of such properties of the system as nonlinearity, openness, dissipativity. To successfully use this direction, objective data on the nature and degree of influence of each of the acting factors on the system are needed. A synergetic effect in relation to exogenous processes can consist, firstly, in the simultaneous action of several forces or factors on the process under study. It can manifest itself the more, the greater the relationship between the elements of the system. For example, the presence of a slope with a soft soil covering, under which a relatively smooth, impermeable rock is concentrated; heavy precipitation penetrating the boundary between soft soil and impermeable rocks, etc. Secondly, the system must have various options for possible development that cannot be predicted in advance. Such expected processes include landslides, mudflows, avalanches, floods. Depending on specific conditions, these processes can have varying degrees of intensity.

II. Methods

The work is based on methods of system analysis and generalization of available materials using a synergetic approach. The basis for the work were stock, archival materials and published literary sources on the subject of the study, both domestic and foreign. The territory of the Chechen Republic is located within the Eastern Caucasus, which is characterized by specific features that create favorable conditions for the development of dangerous natural and man-made geodynamic processes - a thick layer of clay rocks, strong development of erosional dissection and folded forms, the activity of modern movements of the earth's crust, anthropogenic impact, etc.

Various types of exogenous processes are developed in the territory under consideration. Landslides and mudflows are especially active in the mountainous part, the intensity of which depends, first of all, on the lithological composition and properties of the rocks that make up the earth's crust of a particular territory. In some areas, one of the key factors is also anthropogenic activity: laying of communication lines, deforestation of slopes, laying and widening of roads, etc. A number of scientific articles are devoted to landslide processes in the territory of the Chechen Republic [1, 6]. This work focuses on the synergism of their manifestation.

Synergism of exogenous processes, as noted above, can consist of the synchronous manifestation of landslides, mudflows and floods in appropriate conditions. The material for the mudflow is the lithomass from the landslide area.

Synergy consists in the fact that heavy rains lead to a rise in the water level in rivers and, accordingly, to the erosion of banks composed of easily eroded rocks.

An example of landslides most typical for low-mountain forest-steppe landscapes is the landslide near the village of Belgatoy. It begins at approximately an altitude of 766 meters (below the old mosque) and ends on an alluvial fan superimposed on a river terrace that steeply drops off to the river bed.

The Belgatoy landslide develops on Neogene deposits represented by interbedded sandy argillites with multiple aquifers. They are exposed as the landslide deepens, forming a temporary watercourse in the thalweg part of the erosion-landslide cirque, which, passing the alluvial cone in the lower part, cuts into the depth of up to 5 meters.

III. Results

The dynamics of landslide processes over the past 10 years (2011-2021) shows that landslide and erosion-landslide processes remain active. This is noticeable, first of all, in the remaining unsodded areas in the erosion-landslide cirque.

In general, the integration of the Belgatoy landscape-landslide complex into the landscape structure strongly depends on the geomorphological features and moisture conditions of this territory. Currently, due to anthropogenic activity, the relief, soil and ground moisture conditions have been significantly transformed. The construction of multi-storey buildings, bridges and roads in the 60s of the 20th century, the intensification of agriculture contributed to the activation of landslides, the apogee of which was the catastrophic landslides of 1989 [3, 5]. Another area of active landslide processes is the Benoy-Sayasan-Zandak area of the eastern Black Mountains, where Sarmatian deposits composed of clay rocks come to the surface. That is, the dependence of the occurrence of landslides on the material composition of the rocks that make up the area is clearly visible.

Since the early 1960s, landslide processes have repeatedly intensified in the mountainous part of the Chechen Republic, causing enormous damage to many settlements located there. In this regard, the problems of predicting landslide processes and developing effective methods to combat them, taking into account the specific features caused by many factors that are tied to the studied area, are relevant. An example of effective measures taken to combat landslides in the village of Khochi-Ara, Nozhai-Yurtovsky District, are the events, the essence of which was as follows: a trench 1-1.5 m deep was dug across the mountain slope at an angle of 20-250, the bottom and lower wall of which were lined with polyethylene film. It promotes the flow of water along the drainage ditch. A special drainage pipe was placed on the film, which was covered with crushed stone from above. In turn, this entire system was wrapped in a special material and covered with earth. Landslide processes are also prevented by a concrete barrier along the road, poured as a foundation for the fence. Over the past 8 years since the completion of these works, no manifestations of landslides have been detected.

Another example confirming the effectiveness of the proposed anti-landslide system: in the village of Benoy-Vedeno, Nozhai-Yurtovsky district, landslides began, which were approaching a recently built house every year. According to our recommendation, a protective system was built, which consists of drainage and a concrete wall. It has been working normally for two years, but further monitoring is required. An important factor is the fall of heavy precipitation, which could provoke landslides.

In general, the territory of the Chechen Republic is divided into mudflow-hazardous areas of 4 categories according to the activity of mudflows [4] (Figure 1).

Figure 1: *Complex natural landslide in low mountain forest landscapes (Goy-chu river gorge)*

The formation of an oil-producing complex together with the section of the geological environment covered by it can be considered as a complex open natural-technogenic system caused by the synergy of a number of factors. There are many examples of the manifestation of dangerous geodynamic processes during long-term exploitation of oil and gas fields (technogenic seismicity, subsidence of the daylight surface, etc.). The problem of technogenic seismicity during the development of mineral deposits is relevant for many countries with developed oil production. Technogenic processes (such as various types of flooding, induced seismicity) cause significant damage to structures and complicate the process of developing new territories [10].

Technogenic seismicity is characteristic of some developed hydrocarbon fields of the Tersko-Sunzhenskaya oil and gas region , in particular, for the Starogroznenskoye and Gudermesskoye oil fields. Within the Starogroznenskoye field, earthquakes of low intensity associated with its development were noted in 1938, 1963, 1971, and at Gudermesskoye – in 1950, 1955, 2008. The relationship between seismic activity and the dynamics of oil production from these fields indicates the active development of geodynamic processes.

IV. Discussion

Thus, the paper attempts to consider geological processes in the Chechen Republic from the point of view of a synergetic approach. The main factors influencing the intensity of geological processes are identified. It is shown that the synergism of landslide and mudflow processes in the territory under consideration consists of the simultaneous and joint action of various factors, which at the same time increase the intensity of their occurrence [3,9]. Manifestations of mudflow and landslide processes in the territory of the Chechen Republic are quite active. When they occur, great damage is caused to landscapes and infrastructure of mountainous areas. Communications of settlements, inter-settlement and inter-district highways are exposed to such danger (Figure 2). The synergism of dangerous geodynamic processes (landslides, voids, subsidence of the earth's surface, man-made seismicity) in the development of hydrocarbon deposits consists in the fact that the formation of these processes occurs through the collective action of many factors and conditions, which are based on geomechanical processes [7,11]. When developing oil and gas fields, the moment of occurrence of dangerous geodynamic processes corresponds to the so-called "bifurcation" point.

In our opinion, further studies of the considered and similar exogenous processes in the aspect of synergism can lead to practically important results. On this basis, various theoretical generalizations are possible, which, in turn, can contribute to the development of methods for predicting these processes.

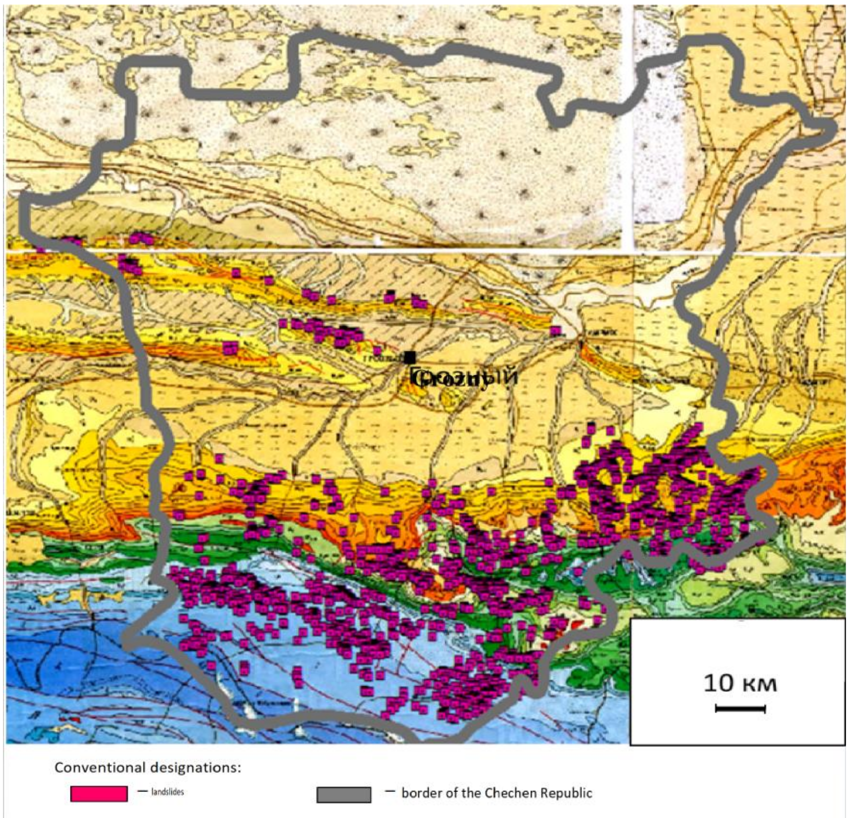

Figure 2: *Spatial distribution of landslides based on the geological map of the Chechen Republic*

The geological structure of the mountainous part of the Chechen Republic is characterized by the participation of a wide range of sedimentary rocks from the Lower Jurassic to the Quaternary period. Moreover, the older rocks are in the south, and are replaced by younger ones as one moves north. The highlands are represented by Lower and Middle Jurassic deposits of flysch rocks, consisting of interbedded siltstones, sandstones and argillites. To the north, in the midlands, the flysch deposits are replaced by a complex of carbonate deposits from the Upper Jurassic to the Lower Cretaceous, consisting of limestones, partially dolomitized, as well as clays and marls. Upper Cretaceous rocks are represented, as a rule, by limestones and marls. To the north of the Upper Cretaceous rocks, there is a belt of Paleogene-Neogene clayey deposits, representing a low-mountain belt. In the lowest part, there are Maikop clays, and higher up, there are Karagan-Chokrak deposits, which, in addition to clays, contain sandstones. Even higher up are the Sarmatian and Akchagyl-Apsheron clayey deposits [2, 8]. The same rocks – from the Maikop to the Akchagyl-Apsheron stages – also make up the Forward Ranges. Between the Forward Ranges and the Black Mountains, Quaternary deposits are widespread, represented by pebbles and sands with clay interlayers (Figure 3).

According to their susceptibility to landslide formation, four main types of rocks are distinguished within the study area: Paleogene-Neogene clays, Cretaceous-Jurassic calcareous rocks, Jurassic siltstones and sandstones, and Jurassic argillites and sandstones.

Figure 3: *Landslide processes near the Nozhai-Yurt - Sayasan highway*

In the southern highland part of the territory, Lower Jurassic argillites predominate, which are close in composition to clays. Therefore, they often serve as an aquiclude, facilitating the development of landslide processes and corresponding relief forms. To the north, a narrow strip of Middle Jurassic siltstones stretches, more dusty, sandy. They are a fertile substrate for soils, in particular, in the Galanchozh intermountain basin, which is considered the historical core of the Chechen settlement, as well as in the Itum-Kalinskaya and Sharoy-Argunskaya intermountain basins. In the northernmost part of the studied territory, Upper Jurassic and Lower Cretaceous rocks are widespread, represented by chalk. They form the Pastbishchny Ridge. Carbonate soils, karst, and partly also gypsum karst are developed in these areas. Significant areas in the northernmost part of the territory are occupied by Paleogene-Neogene clay deposits.

Acknowledgments

The research was carried out within the state assignment of Ministry of Science and Higher Education of the Russian Federation (theme No. №075-03-2021-074/4).

Abstract

The article outlines the technical and economic aspects and relevance of reducing carbon dioxide emissions into the atmosphere in the Republic of Azerbaijan (AR). It is noted that transforming Azerbaijan into a clean environment is one of the priorities of the national program "Azerbaijan 2030". The main sources of carbon dioxide emissions into the atmosphere in the AR have also been studied. Several consequences of carbon dioxide emissions into the atmosphere and possible (necessary) actions to reduce them are given. The basics of carbon dioxide retention in the geological structures of the earth and the main criteria for assessing geological objects for their disposal are analyzed. It is indicated that in order to reduce the long-term consequences of global warming, the technology of capturing, transporting and recycling and (or) burying carbon dioxide is considered as one of the key technologies. It is noted that in order to create an underground storage facility for injection of carbon dioxide gas, the geological structure in the subsurface must meet certain criteria. It was revealed that the most suitable objects for creating projects for the disposal of carbon dioxide gas in the subsurface are the depleted oil and gas fields of the Apsheron Peninsula.

Keywords: carbon dioxide, atmosphere, burial, injection, geological structure, renewable energy sources

I. Introduction

The climate agenda, the rise of global energy consumption and the electricity costs reduction have led to a sharp increase in the production volume of renewable energy sources, and their market share has been growing steadily over the past few decades.

Transforming a country into a one with a clean environment is one of the priorities of the national program "Azerbaijan 2030". All issues listed in the Priorities are extremely important for the sustainable development of the country (Fig. 1). In recent years, the Republic of Azerbaijan has been making every effort to participate in the global processes of the "great energy transition of 2030" [1-4].

The Conference of the Parties to the United Nations Framework Convention on Climate Change, or the COP, is a large government-level meeting dedicated to developing a common climate strategy. The 29th COP is planned to be held in Azerbaijan in 2025. Holding the COP 29 in Baku is an endorsement of the country's contribution to environmental protection and the prevention of climate change at the national, regional and global levels. The UNO expressed confidence that the AR will hold the COP 29 at a high level, and this will be another great success for the country, as well as a contribution to slowing down climate change [4].

Figure 1: *Main priorities of social and economic development of the AR*

According to the International Energy Agency (IEA), global carbon dioxide (CDG) emissions will reach record levels in 2023. These emissions are energy-related, largely due to the increased use of fossil fuels. Greenhouse gases (carbon dioxide, CO2) are the most important source of climate change. They are estimated to be responsible for approximately 64% of global warming. The IEA notes that to achieve the global climate goals set in the Paris Agreement, sharp reductions in carbon dioxide emissions, in particular the combustion of fossil fuels, are necessary [5, 6].

The Paris Agreement on Climate Change adopted in 2015 (the COP 21) set participating countries goals to reduce greenhouse gas emissions and limit global warming to 1.5-2 degrees Celsius compared to pre-industrial levels (the period of 1850-1900) [7].

Azerbaijan is also a party to the Paris Agreement, and has made a voluntary commitment to reduce greenhouse gas emissions by 35% by 2030 compared to 1990, and by 40% by 2050. This agreement and all subsequent COPs are dedicated to the implementation of the key goal of this document – keeping the global average temperature rise to 2°C (global peaking) and continue efforts to limit the increase to 1.5°C (climate neutrality). Today, one of the main reasons for climate warming is "greenhouse" emissions into the atmosphere, among other gases, primarily carbon dioxide, the release of which is natural and anthropogenic, is leading (Fig. 2).

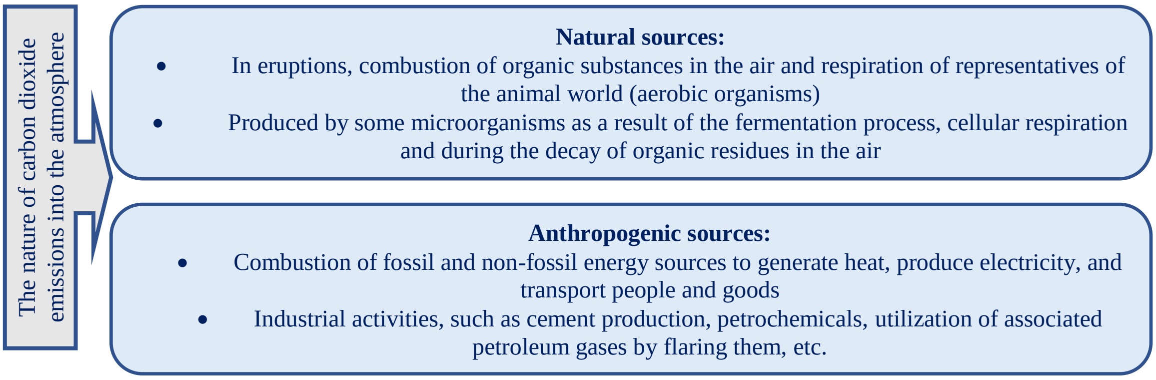

Figure 2: *Nature of carbon dioxide emissions into the atmosphere*

As is known, the main anthropogenic sources of carbon dioxide emissions into the atmosphere are of an industrial (energy) nature (Fig. 3).

II. Methods

The study used the analytical method, the method of comparison. Methods for collecting, processing and analyzing information were determined by the specific objectives of the study based on a systematic approach. Based on the analysis of extensive material, a review of existing options for the utilization and storage of carbon dioxide in the subsurface has been prepared.

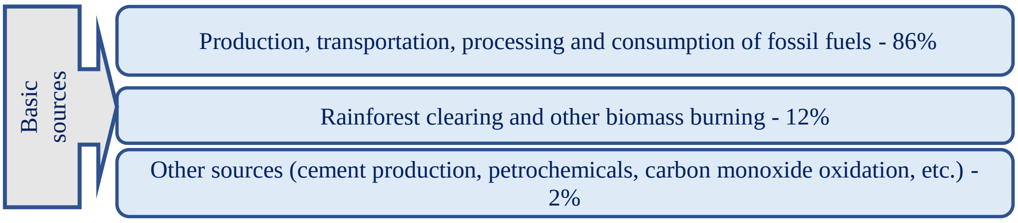

Figure 3: *Main sources of carbon dioxide emissions into the atmosphere*

III. Research results and discussion

According to the IEA, in 2022 alone the volume of emissions amounted to 36.8 billion tons and in 2023 from the energy sector they increased by 410 million tons, or 1.1%, reaching 37.4 billion tons. The increase in carbon dioxide emissions into the atmosphere has serious consequences (Fig. 4). The main volume of about 70% of global CDG emissions comes from electricity and heat generation and transport [5, 8, 9].

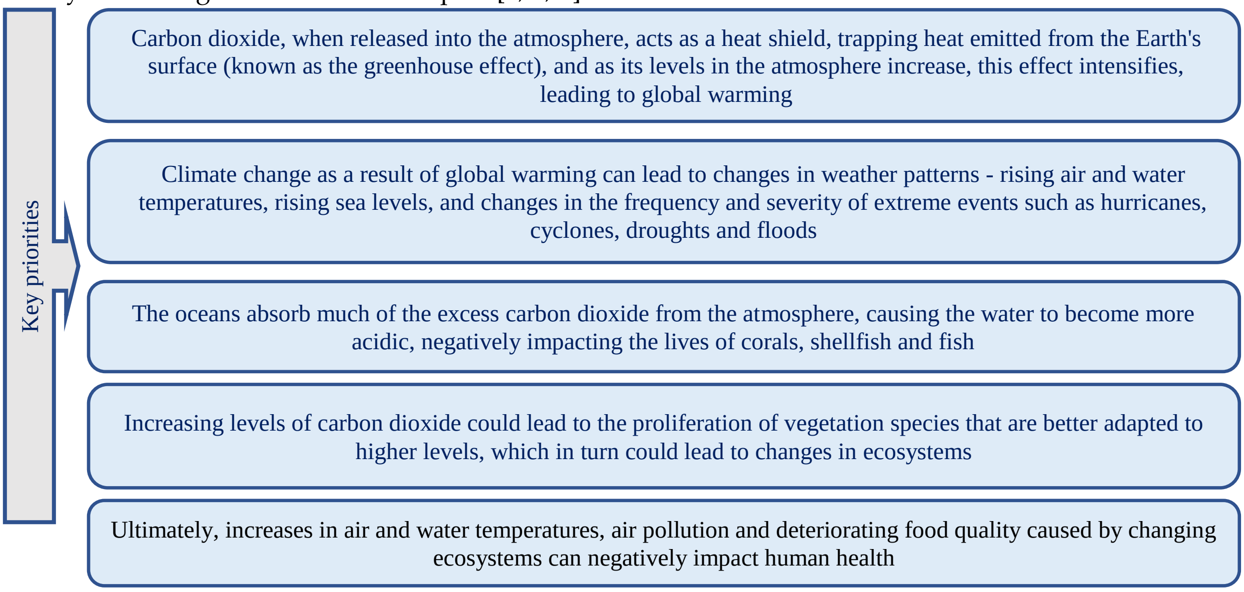

Figure 4: *Some consequences of carbon dioxide gas emissions into the atmosphere*

To reduce greenhouse gas emissions into the atmosphere, the Republic of Azerbaijan is implementing a number of projects, including paying special attention to the production of renewable energy sources (RES). However, additional measures must be taken to reduce atmospheric carbon dioxide emissions (Fig. 5).

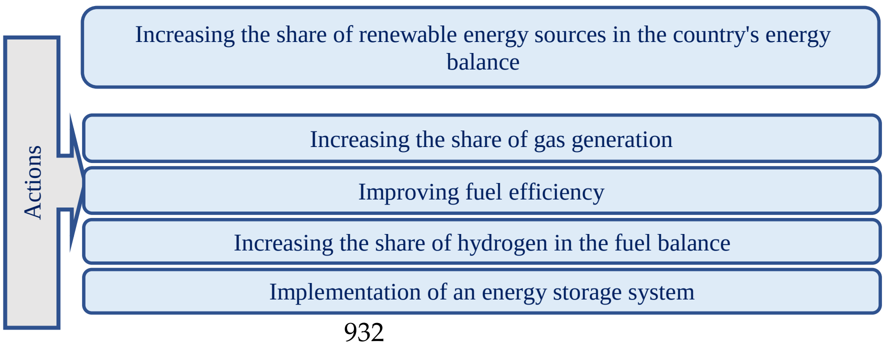

Figure 5: *Action is needed to reduce carbon emissions into the atmosphere*

The development of the petrochemical industry in the AR is accompanied by an increase in greenhouse gases that require disposal. One of the by-products of petrochemical production is carbon dioxide. According to the requirements of state supervisory authorities, production and industrial enterprises must limit the release of carbon dioxide.

The technology for CDG capturing, transporting and disposal (and/or recycling) is currently considered one of the key technologies for mitigating the effects of global warming [9-11]. A VOC removal technology can have two main goals: preventing new VOCs from entering the atmosphere or eliminating previous emissions. The technological chain of CCS elimination projects includes a number of processes [12-14]. (Fig. 6).

Burying CDG means pumping it underground to a depth of 800 meters or more. The geological properties of underground reservoirs determine the reliability of this storage. Porous rocks from depleted hydrocarbon deposits that have contained fossil fuels for millions of years are among the most suitable. Based on foreign experience, depleted hydrocarbon (HC) deposits and geological aquifer structures can be used as objects for disposal of hydrocarbons [15, 16].

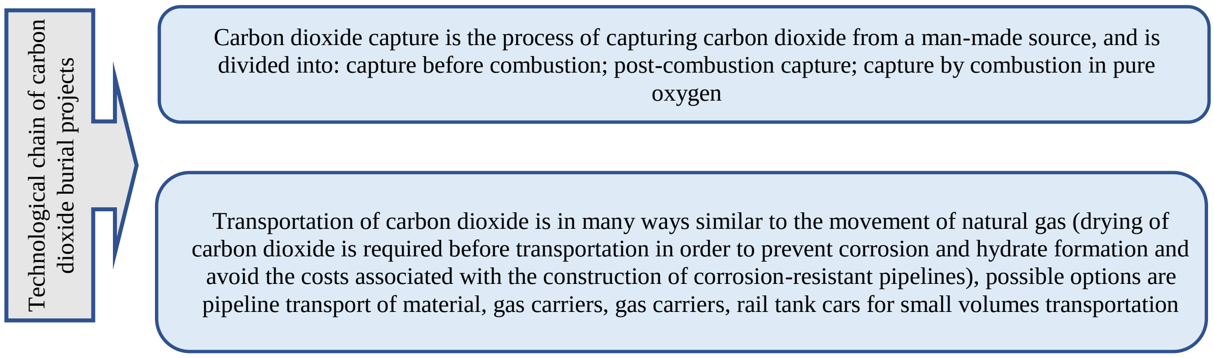

Figure 6: *Some consequences of carbon dioxide emissions into the atmosphere*

Norway was one of the first countries to implement projects to capture carbon dioxide from factories and pump it into subsurface storage facilities. The number of CDG phase-out projects around the world has grown rapidly in recent years, and there are currently 29 such projects (Table 1). The current capacity of CDG phased disposal projects around the world, amounting to about 40 million tons per year, can capture only slightly more than 0.12% of global carbon dioxide emissions [9, 17, 18].

Table 1: *Distribution of carbon capture, utilization and storage by regions (2022)*

Region	Active	In developing	Suspended	Total by region
North America	16	80	2	98
China	4	3		7
Europe	4	46		50
Persian Gulf	3	1		4
The rest of the world	2	11		13
Total	***29***	***141***	**2**	***172***

Four main mechanisms remain at the basis of the retention of CDG in the geological structures of the Earth (Fig. 7).

The principles of carbon dioxide retention in the geological structures of the Earth consist of four main provisions (Fig. 7), where the degree of carbon dioxide retention is determined by the potential of the underground storage (geological structure) [11, 17].

Special requirements must be placed on the geological conditions and characteristics of CDG storage tanks to ensure the safety of long-term storage of injected products. Leaks of CDG, even those to ensure the safety of underground sources of drinking water supply, as well as leaks to the surface must be excluded [11, 19, 20].

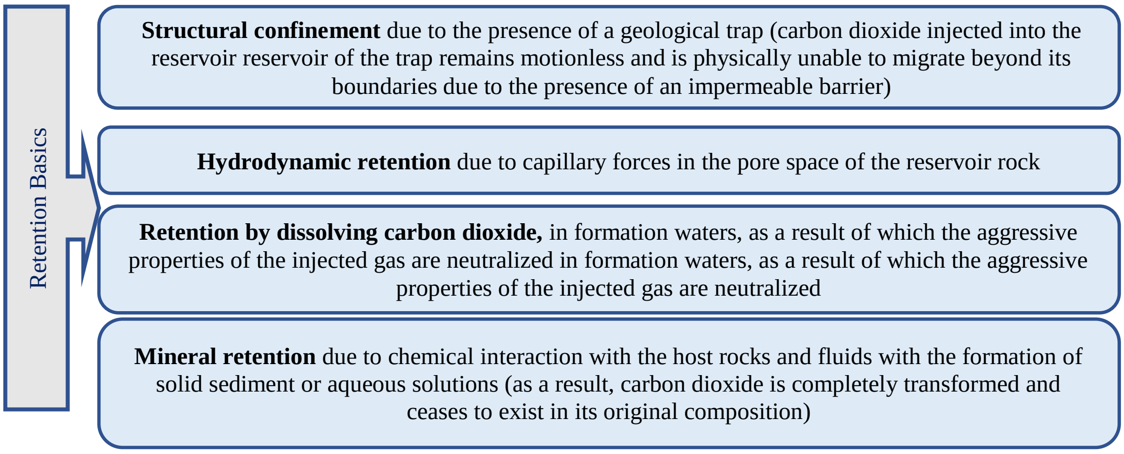

Figure 7: *Basics of carbon dioxide retention in the geological structures of the earth*

To create an subsurface facility for carbon dioxide injection, the geological structure in the earth interior must meet certain criteria (Fig. 8).

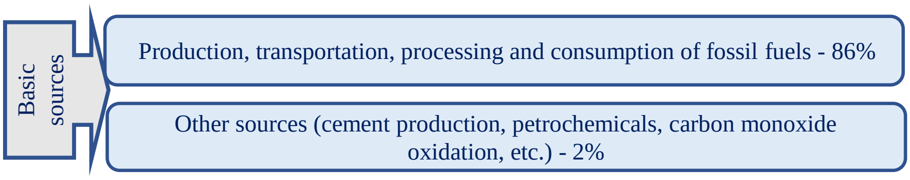

Figure 8: *Basic criteria for assessing geological sites for carbon dioxide disposal*

Natural geological structural traps (reservoirs) with certain thermobaric conditions ensure the safety of the injected CDG at reservoir pressure at the end of injection of a given volume to the initial reservoir pressure. One of the problems regarding the process under consideration is the distribution and distribution speed of the CDG throughout the volume of the natural trap.

Disposal of CDGs in depleted deposits must be carried out not only while maintaining the tightness of the underground reservoir, but also while ensuring the absence of lateral flows of CDGs along the roof of the trap. Therefore, when injecting carbon dioxide into a reservoir, monitoring the distribution of carbon dioxide throughout the reservoir becomes an urgent problem.

Monitoring techniques, first of all, must meet the requirements of accuracy and reliability of determining the gas-water contact. However, an important factor is the simplicity and cost-effectiveness of the technique. Accordingly, the choice of a suitable monitoring technique can specified through choosing the simplest and most economical one, in order to then consider the degree of its reliability and draw a conclusion about the validity of its application One of the simplest and most economical techniques is gravimetric monitoring, based on recording changes in the Earth's gravitational field. When carrying out gravity surveys, data are obtained that describe the gravitational field created by the underlying strata of the earth. In order that the obtained data from gravimetric studies be the most representative, they must be carried out with confidence in the established regime in the formation. This approach will eliminate the anomalous pressure increase in the reservoir associated with the inhibited propagation of the hydrocarbon gas in the reservoir, since without identifying the increase in pressure there is a high risk of reducing the tightness of old wells [21-23].

When making a qualitative interpretation of gravimetric monitoring data, it is necessary to mention the possibility of registering the threat CDG may cross the trap's closing isohypsum using the proposed technique. By controlling the distribution of carbon dioxide throughout the reservoir using gravimetric monitoring, it is possible to stop its injection in time to prevent the flow of carbon dioxide through the structural trap.

To justify the selection of promising geological objects for placement (creation of an underground reservoir) on the basis of depleted deposits for the placement of CDG, it is necessary:

- to identify promising facilities for carbon dioxide storage;
- to assess the potential for carbon dioxide storage in selected facilities;
- to perform a technical and economic analysis of the transportation of CDGs in various ways to selected storage facilities.

Based on a technical and economic analysis of different methods of transporting the projected volume of CDG emissions, it is possible to recommend appropriate geological structures as the subsurface part of operational disposal facilities. The results obtained will be used to substantiate the initial data for the technological design of the construction of an operation facility for the disposal of carbon dioxide gas.

IV. Conclusion

Achieving global goals for economic decarbonization is impossible without implementing projects to capture, transport and use (or) bury carbon dioxide. One of the most important factors for these projects to be successful is the availability of geological facilities for safe long-term storage of carbon dioxide. At the same time, the accumulated experience in the gas business (transportation, underground storage, etc.), including sour gases, as well as access to extensive geological information gives the oil and gas industry a global advantage, allowing it to exploit the AR potential in the field of CDG disposal in the earth interior. According to preliminary estimates, the most suitable sites for creating projects for the use and storage of greenhouse gases in the Azerbaijan interior are located in traditional oil and gas production areas, mainly on the Absheron Peninsula.

The current tasks of developing a new technology for the AR are a targeted geological study of various conditions for storing carbon dioxide in the subsurface and the development of uniform regulatory requirements for the geological parameters of underground carbon dioxide storage structures. In addition, it is important to examine the long-term liability issues associated with establishing ongoing geological monitoring of possible leaks from underground carbon dioxide storage in the subsurface. The gravity monitoring technique allows monitoring the condition of the field into which carbon dioxide is injected.

Azerbaijan's potential in terms of the use and burial of carbon dioxide underground is quite high, but it has not been fully assessed yet, and today there are no industrial projects for the burial of carbon dioxide in the bowels of the country. Additional actions are necessary to implement the above-described project to reduce greenhouse gas (carbon dioxide) emissions into the atmosphere.

PART-3

ENSURING RESILIENCE OF SPATIAL DEVELOPMENT IN THE CURRENT CLIMATE REALITY

SPATIAL DESIGN ACTIVITY IN THE CURRENT CONTEXT OF HIGH CLIMATE UNCERTAINTIES AND RISKS

Georgy Fomenko
•
Institute for Sustainable Innovation, Yaroslavl, RUSSIA
info@npo-kad.ru

Abstract

The article explores the characteristics of the ongoing transformation of spatial design activities in the current context of high climate uncertainties and risks. A comprehensive methodology of Sustainable Ecosystem Design (SED) is proposed as a special type of thinking activity, based on a systemic approach to decision-making and emphasizing the adaptation of individuals and communities to high climate risks and uncertainties. This planning and design thinking is capable of better reflecting the diversity of broadly understood geographical conditions, expanding the range of socially and culturally acceptable solutions for sustainable development in an unstable and risk-prone environment.

Keywords*:* spatial planning and design, sustainable ecosystem design, climate uncertainties and risks, sustainable development, anthropo-natural systems

I. Introduction

Climate change is a critical risk multiplier that triggers or exacerbates spatial development crises. The impacts of climate change pose threats to food security, health, biodiversity, infrastructure, economy, and finance [1]. The multiplicative effect of climate risks is evident in the crisis faced by governance, planning, and spatial development institutions, which were established under previous environmental and climatic conditions. In other words, within the new environmental and climatic reality, these institutions can no longer be managed according to the conventional metrics developed under classical planning paradigms. This is evidenced by the increasing damage to the well-being of the majority of the planet's population.

In the current context of high climate uncertainties and risks, the existing spatial model of decision-making regarding economic activities is rapidly losing its effectiveness. This decline is a result of the ever-increasing budgetary expenditures required to mitigate damages from natural disasters, with significant compensation costs being deferred to future generations. It is unreasonable to continue designing agricultural policies, constructing roads and erecting buildings in the same manner as before, continually spending resources on reconstruction or rehabilitation due to the adverse effects of climate change that jeopardize public finances and social well-being.

Climate risks are not new; humanity has always responded to epidemics, floods and droughts. History shows that significant climate change has driven some countries to the brink of disaster, while others have successfully adapted to new, challenging realities [2]. The modern risk-reflection of society on the current situation is expressed in growing concern not always accompanied by reasonable actions. The reality is illustrated by the sharp increase in negative news globally, especially after 2020[1] . In such moments, people are overwhelmed by doubts that can either paralyze their ability to act or drive them to unreasonable radical decisions[2] .

People's risk-reflection on climate change lags behind the escalating climate threats, resulting in preventive measures often being delayed. Effective protective actions are typically taken during natural disasters usually perceived by the population as unexpected "black swans"[3] . The situation is exacerbated by the short planning horizon and paternalistic traditions prevalent among a large part of the population, where people, despite being aware of climate threats, are generally reluctant to engage in broadly understood risk insurance through proactive protective measures. The danger of climate vulnerability is frequently underestimated despite N. Stern demonstrating more than ten years ago that the cost of inaction on climate change far exceeds the cost of taking measures [3]. Scientists have calculated that scientifically adapting infrastructure to climate change is highly cost-effective, with a global net present value exceeding 2.5 trillion USD[4] [4]. Considering this phenomenon, G. White [6] noted that people make decisions based on practical choice established by culture and institutions, rather than theoretical choice established by the physical environment (in this case - climate scientists (auth.). In such context, the risks of "gray swans" and particularly dangerous "pink flamingos" increase[5] .

In the context of increasing climate risks and uncertainties, the search, development and implementation of new mechanisms of decision-making regarding spatial development, integrating climate adaptation measures and reducing climate impacts characterized by synergy and long-term sustainable effects, has become more relevant. In the most climate-vulnerable regions and locations, there is an urgent need to rethink urban planning regulations, technological standards and long-established zoning practices. This article examines one such systemic and comprehensive mechanism.

II. Methodology

Spatial design activities under conditions of high climate uncertainties and risks of the "full" world of the Anthropocene are still developing methodologically, as well as the understanding of this new reality of the 21st century [7]. In any case, the real world remains far from the noosphere - the sphere of spirit according to Teilhard de Chardin [8] or the sphere of reason according to V. I. Vernadsky [9]. The most dangerous aspect of the "full" world is its high-risk nature, characterized by the production, distribution and "consumption" of risks [10-14].

It is the risk-reflection regarding the vulnerability of the new world that creates the need for a shift in the fundamental approaches to spatial design activity [15], with an increased emphasis on maintaining the viability of anthropo-natural systems (ANS)[6] , in which humans are not considered beings "accidentally separated" from and opposed to nature. On the contrary, humans play a dominant role, unfortunately simplifying and sometimes destroying ecosystems, as well as creating new, previously impossible ones, including dangerous interactions with living nature.

As institutional systems of the "full" world emerge, it is methodologically important to prevent the appearance of negative strange attractors - future scenarios without humans. This concern underlies the commitments of many countries to gradually transition to carbon neutrality in an effort to slow down climate change. However, the high degree of uncertainty inherent in

[1] The analysis of over 14 million sources, providing publications over the past 125 years in three major languages, showed a sharp increase in anxiety and concern in many parts of the world [2].

[2] The situation is further complicated by the increased danger of climate-related misinformation in the age of global internet access, hindering effective measures for climate adaptation and mitigation.

[3] As N. Taleb wrote in his bestseller, a "black swan" is a catastrophic event that cannot be predicted.

[4] This was later confirmed by numerous studies, although the estimates of the scenarios considered vary: out of approximately 3000 different scenarios, 2904 have cost-benefit ratios less than one [5].

[5] Unlike "black swans", "gray swans" are, although unlikely, still predictable catastrophic events. The most dangerous variant of "gray swans" is "pink flamingos." This term refers to a class of predictable disasters whose risks are ignored due to the cognitive biases of decision-makers, influenced by institutional interest groups.

[6] The anthropo-natural system is a constantly evolving living organism, whose laws of survival and development have formed over billions of years of evolution and periodically undergoes a phase transition before entering a new stage of dynamic stability.

climate knowledge complicates this process. M. Weitzman is particularly categorical in his "dismal theorem," asserting that the uncertainties associated with future climate change are so significant that there is a non-negligible probability of catastrophe. According to M. Weizmann, the danger lies in the tails of the probability distribution of climate risks, where there may be an unexpectedly thick end or "fat-tailed distribution," meaning the tails never entirely diminish [16].

Spatial planning activities under conditions of high climate uncertainties and risks within the "full" world of the Anthropocene are still developing methodologically, as is the understanding of this new 21st-century reality [7]. The real world remains far from the noosphere—the sphere of the spirit, as described by Teilhard de Chardin [8], or the sphere of reason, as conceptualized by V. I. Vernadsky [9]. The most perilous aspect of the "full" world is its high-risk nature, characterized by the production, dissemination, and "consumption" of risks [10-14].

It is the risk-reflexivity regarding the vulnerability of the new world that necessitates a shift in fundamental approaches to spatial planning activities [15], with an increased emphasis on maintaining the viability of anthropogenic-natural systems (ANS), wherein humans are not considered beings "accidentally" separated from and opposed to nature. On the contrary, humans play a dominant role, unfortunately simplifying and sometimes destroying ecosystems, as well as creating new, previously impossible ones, including dangerous interactions with living nature.

As institutional systems of the "full" world emerge, it is methodologically important to prevent the appearance of negative strange attractors—future scenarios without humans. This concern underlies the commitments made by many countries to gradually transition to carbon neutrality in an effort to slow down climate change. However, the high degree of uncertainty inherent in climate knowledge complicates this process. M. Weitzman is particularly categorical in his "dismal theorem," asserting that the uncertainties associated with future climate change are so significant that there is a non-negligible probability of catastrophe. According to Weitzman, the danger lies in the tails of the probability distribution of climate risks, where there may be an unexpectedly thick end or "fat-tailed distribution," meaning the tails never entirely diminish [16].

Given a scenario where the probability of a global climate catastrophe is minimal yet existent, and its consequences tend toward infinity (self-destruction of a significant portion of the planet's population), it is essential to align with UNESCO's position[7]: For humanity to prioritize climate change risks, we need to change mindset [17]. It is most important to increase the value of the responsibility in the behavioral model of economic activity as a foundation for changing the priorities and structure of economic activity (Tab. 1).

Table 1: *Traditional vs resilience approaches to spatial planning and design*

Approaches to spatial planning and design	
Traditional approach	*A resilience approach*
Considers the object or process individually	Considers the entire anthropogenic-natural system (ANS) in which the object or process will be used
Focused on technical issues	Synergistically addresses both technical and non-technical issues
Solves immediate problems	Aims to solve problems permanently or for the longest possible term
Takes into account the local context	Considers local, national and global contexts
Assumes others will address political, ethical, and social issues	Recognizes the necessity of engaging with a wide range of experts in sociology, ecology, etc.
Ignores the importance of achieving carbon neutrality	Focuses on ensuring carbon neutrality

[7] https://ru.unesco.org/themes/obrazovanie-v-interesah-ustoychivogo-razvitiya-0.

The task of reducing climate development risks and enhancing the resilience of anthropo-natural systems (ANS) is addressed by the author's development of the Sustainable Ecosystem Design (SED) tool [18-20]. The subject of SED is practical activity systems that can be identified, described and turned into objects of goal-oriented spatial development transformations in an unstable external environment to improve the resilience of ANS. In other words, it represents a particular approach to reality, focusing on exploring the possibilities, methods, and means of "restructuring" a fragment of reality to align it with "some idea", an ideal with carbon neutrality, preserved biodiversity and high-quality human life. In the current conditions of high climatic uncertainties and risks, spatial planning and design activities are justifiably based on the principles, structures and processes of Risk Management standards (such as GOST R ISO 31000-2019 in the Russian Federation [21] and others), which are oriented to adapting to the increased probabilities and severities of climate change impacts.

SED is implemented through the design of climate-resilient systems and spatial infrastructures that integrate human society with its natural environment for the benefit of both. The essence of SED lies in an ethically oriented, goal-appropriate, systems approach to designing the development of ANS. The primary focus is on coordinated actions in adaptation[8] and mitigation[9] within public administration, economic sectors and infrastructure in response to changing climatic conditions. Driven by their goals, humans consume, conserve, and create ecosystem services.

In SED, priority is given to climate-related, natural-biological, and socio-cultural constraints and regulations, which create a regulatory framework, or "bubble" into which it is necessary to fit increasingly complex economic activities. As a result, the importance of ecosystem regeneration[10] increases as well as of nature-oriented solutions, the potential for cyclical economic development based on balanced and other approaches. The system of constraints and regulations inherent in SED (in some ways extending urban planning norms) reduces the likelihood of hypothetical negative development trajectories for ANS.

III. Results

The research conducted by the author in the Russian Federation, the Kyrgyz Republic and the Republic of Uzbekistan on climate-related issues, with a focus on achieving a synergistic effect of climate adaptation and mitigation measures, has confirmed the effectiveness of institutional approaches to to Sustainable Ecosystem Design (SED) as a special type of spatial planning and design. Under conditions of high climate uncertainties and risks, SED is considered as a goal-oriented activity aimed at implementing sustainable development approaches for territories and settlements. In terms of form, represents forward-looking long-term planning, while in terms of the content of planning decisions, it pertains (with rare exceptions) to strategic planning and is seen as a goal-oriented activity to implement sustainable development approaches for territories and settlements under high risks and uncertainties.

Theoretical model. SED involves a systemic vision, pragmatic solutions, and methods that help coordinate disparate efforts in green architecture, sustainable agriculture, eco-engineering, and more. It is characterized by an indisputable ethic of Life, recognizing the inherent value of all living things. SED can be described using a four-pillar dynamic sustainability model (Figure 1),

[8] Climate change adaptation means planning and taking measures in response to expected climate change impacts. This includes making changes to how we live and what we do before the impacts occur (proactive action), and being prepared to respond to increasingly likely and frequent extreme events (reactive actions).

[9] Mitigation is a set of measures taken to reduce and mitigate the negative impacts of climate change. Its main goal is to reduce greenhouse gas emissions and the causes of global warming.

[10] Regeneration - restoration, renewal, or compensation of something during the course of activity.

where the three dimensions - social, economic, environmental - are joined by an institutional[11] one with six interconnections.

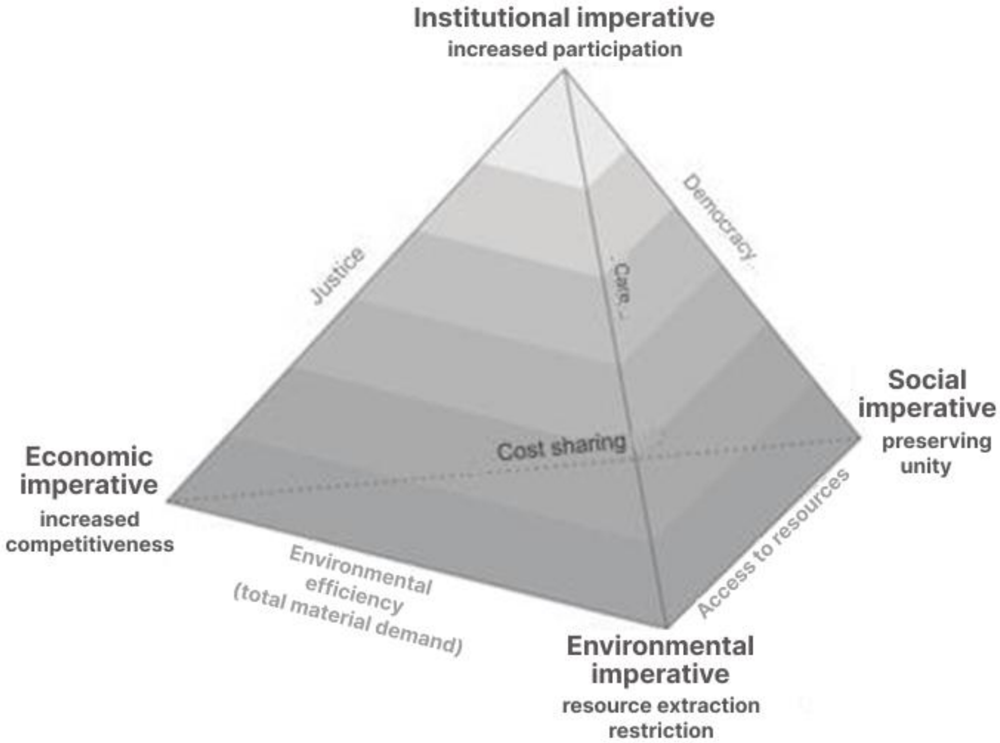

Figure 1: *Four-pillar model of SED under conditions of high uncertainties and risks*
Source: developed by the author based on [22].

The institutional component of sustainability introduces the concept of understanding of value-driven motives and moral incentives for activities aimed at achieving climate neutrality, from local communities to humanity as a whole. The four-pillar dynamic model of sustainability places value on three aspects of development - care, justice, and democracy - derived from the primacy of responsibility for future generations. This value-driven socio-cultural impact, in turn, influences the social, economic, and environmental imperatives (Figure 2). Under high climate uncertainties and risks, this makes spatial development more humane, inclusive, and sensitive to environmental variability[12] .

SED should be viewed as a value-driven, action-oriented, institutional response to ecosystem degradation, increasing climate threats and biodiversity loss. It is a goal-oriented spatial design interdisciplinary approach that seeks to take into account the environmental, social, and cultural features of specific areas when addressing spatial development tasks. It is characterized by the implementation of sustainable development goals; systematic application of regulatory institutions (tools) for ecosystem services; geographical specification of basic methodologies for spatial planning, consideration of the cyclical nature of resource flows; and pursuit of carbon neutrality. In organizational terms, SED relies on the creation of multidisciplinary teams of local specialists and external experts.

SED requires reliable measurements of the contribution of planning and design decisions to people's well-being on a particular territories and the impact of human activities on the environment. There is a growing demand [25] for interdisciplinary synthesis of knowledge based

[11] D. North most successfully defined institutions as "rules of the game" in society, or human-created restrictive frameworks that organize relationships between people. Such institutions (formal and informal) emerged as a behavioral response of people with only partial rationality to threats (real or imaginary) to their security [23].
[12] Of course, the institutional imperative in its Kantian perspective is unattainable, as people are only partially rational and do not possess all information.

on qualitative monitoring observations as the foundation for creating an effective information system for to support spatial design activities in the current context of high climate uncertainties and risks - from primary ecosystem state measurements and analysis of ecosystem service flows (including spatial) to future scenario modeling through knowledge analysis and systematization, aimed at increasing sustainability capital.

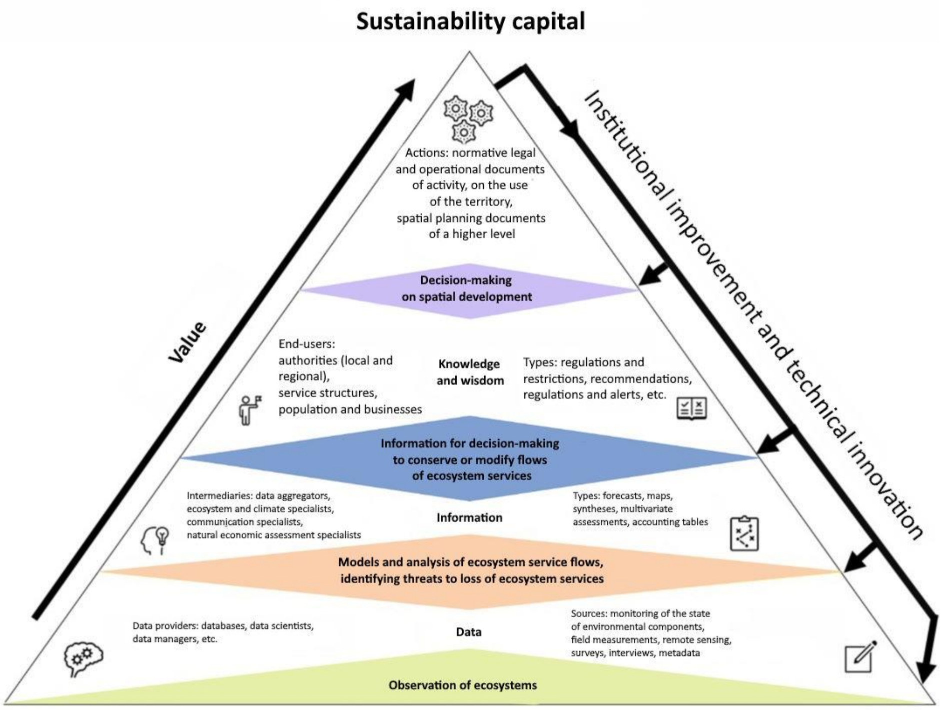

Figure 2: *From ecosystem state observations and ecosystem service flows to sustainability capital*
Source: compiled by the author based on [24].

This chain of creating an effective information system to support spatial design activities in the current context of high climate uncertainties and risks is depicted as a large triangle in Fig. 2. It shows that, starting from its lower part and moving upwards, primary monitoring data are given a higher state status, for example, through statistical and departmental indicators. Subsequently, through generalization within the framework of the System of Environmental-Economic Accounting (SEEA EA) [26, 27], models, and analytics, these systems of indicators are aggregated into complex indicators for assessing the territory development, primarily by the size and structure of the territory's sustainability capital and its dynamics.

The systemic basis for obtaining and transforming knowledge-intensive formalized and dispersed information into knowledge envisaged by the UED allows to ensure the necessary quality of development and analysis of development plans and projects, as well as their assessment for compliance with the goals and approaches of sustainable development, to ensure the search for reasonable trade-offs between different land use options.

Our practical experience in the regions of Russia and Central Asia has shown that natural-scientific and legal knowledge alone is not sufficient for strategic spatial development decisions concerning the future. It is fundamentally important that sustainable development requires wisdom, which expands people's ability to make decisions under high uncertainties and with care for the future.

IV. Discussion

The search for new approaches to the reform of spatial and design for the development of countries, regions, and places is the subject of extensive and rapidly growing literature. An analysis of this literature reveals a broad recognition of the close synergistic relationship between climate change and ecosystem health. regarding the methodological complexity of assessing the impact of extreme risks on socio-economic development. Successful climate adaptation and achieving climate neutrality are not ends in themselves but are crucial criteria for spatial and design activities in an unstable external environment, necessary to ensure the long-term survival of both people and nature.

SED implies goal-oriented integration of practical actions for climate adaptation and reducing negative impacts on the climate from the perspective of minimizing the risks of losing development sustainability. SED is focused on the preservation, restoration, and creation of new viable ecosystems that are important for both humans and biota. It is always territorially specific and unique, combining climate-neutral and sustainable functioning of human and natural spatial systems with engineering and social infrastructures.

The information developed within the framework of SED should enable the application of broadly understood insurance mechanisms, ranging from engineering protective measures to social and economic ones. Insurance for economic risks in the climate sphere is in its infancy due to significant "fat tails" associated with uncertainties. For example, the construction of temperature-independent energy systems or population migration may encounter difficulties in conditions of multi-level and interconnected uncertainties [2]. Addressing this gap has become the focus of the global Network for Greening the Financial System[13].

The principles we set out for a unified system of indicators for evaluating decision-making within the SED and for assessing the efficiency of such decisions allow us to determine the effectiveness of projects and development plans by combining RBM (results-based management) and CBA (cost-benefit analysis) approaches, as well as RIAM (rapid impact assessment matrix). This makes it possible to assess measures within existing informational constraints in terms of their effectiveness, economic efficiency for the innovation beneficiaries, socio-economic efficiency for local communities, and sustainable development of territories in the long term. In this context, while developing SED, we unexpectedly encountered a lack of scientific knowledge about anthropo-natural systems (ANS). The reason for this situation is deeper than it seems at first sight, as it is fundamentally related to the orientation of scientists and experts in biology and ecology towards studying predominantly intact ecosystems. Meanwhile, such knowledge, albeit useful, proved insufficient for the designing solutions of the problems of ensuring the sustainability of ANS, which include industrial, civil and infrastructure facilities.

Despite its obvious demand, SED is still spreading slowly. This is because it imposes increased requirements on the quality of territory study, which requires specialists trained to work in conditions of high climate uncertainties and risks. When using SED tools, the abilities of managers, planners, and designers to think systemically and engage in interdisciplinary interaction come to the forefront; as well as focus on reducing risks of losing viability and ranking these risks; ability to identify and prioritize critical "red points" of effort, ability to work with large data sets and artificial intelligence systems. Widespread use of SED is also hindered by the currently short planning horizon of many resource managers, who perceive the importance of only immediate social and economic tasks and the political conjuncture. They perceive the real tasks of strategic planning as declarative, and scientific activity as disconnected from real life.

Our experience has shown that SED approaches are currently most positively received by people in areas significantly affected by climate change, such as the Aral Sea region or southern Kyrgyzstan, which have suffered from natural disasters or anthropogenic and natural catastrophes.

[13] NGFS - Central banks and supervisors - Network for Greening the Financial System. Scenario Portal. https://www.ngfs.net/ngfs-scenarios-portal/

V. Conclusions

Spatial design activities in the current context of high climate uncertainties and risks require a system-forming SED methodology, which sets the vector for goal-oriented systemic transformations of spatial development in an unstable external environment to enhance the viability of disturbed ANS through a system of planned and project measures for spatial development within interconnected, geographically specific constraints and regulations of economic activity.

SED allows reducing losses and damages through comprehensive development of territory and synthesis of climate adaptation and mitigation measures. It increases the efficiency of public and private investments from the perspective of sustainable development of territories, facilitates sustainable use of natural capital, and enables the education of the population on the sustainable use of development assets and their capabilities in the face of climate challenges.

In the context of the climate agenda, SED is expressed in giving climate-neutral development a human face, perceiving climate threats from a general security perspective, strengthening positive synergies between climate adaptation and mitigation measures, and creating institutional conditions to increase the interest of key economic sectors and a wide range of stakeholders in achieving climate neutrality. And the leading position is taken by the ability of managers, planners and designers to think systemically and engage in interdisciplinary interaction.

DEVELOPMENT OF STANDARDS FOR THE TRANSPORTATION AND STORAGE OF HYDROGEN AS THE BASIS FOR THE SAFETY HYDROGEN'S USAGE

Roman Samsonov[1,2], Daria Michurina[1,2]

•

roman@samsonov.org

Abstract

Today, the standardization of hydrogen is an important topic for increasing its production, while raising many questions. Hydrogen and its derivatives are central components of a decarbonized energy system. On the one hand, many countries are now establishing regulatory frameworks for renewable and low-carbon hydrogen, often accompanied by specific requirements for hydrogen. Similar processes are underway in Germany, Japan and the United States. The article discusses trends in the development of standards for the transportation of hydrogen through pipelines as the cheapest mode of transport and the prospects for creating a unified regulatory framework in this area, allowing the formation of a single world network for the transportation of hydrogen. Based on the results of the study, we came to the conclusion that at the present stage, the standardization of hydrogen is extremely underdeveloped, both on a global scale and at the national level. There are a number of regional initiatives that have not been widely adopted. Therefore, today it is extremely important to develop cooperation in this area at the international level. The Working Party on Regulatory Cooperation and Standardization Policies (WP.6) seems to be a good platform.

Keywords: standards, regulatory policy, hydrogen, certification, requirements

I. Introduction

Global standardization for the transportation of hydrogen fuels is becoming a cornerstone for the implementation of sustainable development goals, since hydrogen is the most promising and environmentally friendly of all possible energy sources today. The most promising in terms of cost is the transportation of hydrogen through existing pipelines, where the development of regulatory requirements for the transportation of hydrogen will make it possible to determine the possibility of using both existing networks and the principles of creating new hydrogen pipelines.

Today, the scientific community pays great attention to the standardization of hydrogen itself (Yang [1], Wurster [2]). However, there is no unified approach to the standardization of hydrogen at the international level. Although it should be noted that there are a large number of regulatory documents developed at the national level of different countries, as well as attempts to develop international standards in this area by the international organization for standardization - ISO. The lack of uniform approaches to the standardization of hydrogen makes it difficult to use, and more importantly, in our view, the development of both hydrogen infrastructure and hydrogen trade exchange.

The prospects for global standardization in the field of hydrogen technologies are very encouraging. States and companies recognize the importance of developing common standards to facilitate the use of hydrogen in various industries, including automotive, energy and industrial. The development of hydrogen transportation, distribution and storage is becoming a key element of hydrogen standardization. Therefore, today the standardization of hydrogen infrastructure is being actively discussed at various venues. An important player in this field is the UNECE Working Party 6, where a project to harmonize different aspects of hydrogen pipelines has been implemented since 2023.

II. Methods

In this study, we relied on the scientific research of such experts in the field of hydrogen standardization as A. Ramensky [3], A. Shvarovsky [4], F. Gale, D. Goodwin, H. Lovell, H. Murphy-Gregory, K. Beasy, M. Schoen.

The methodological basis of our study was the national legislation of the EAEU countries, China, the USA, the European Union, international and regional strategies for the implementation of hydrogen energy, for example, the Roadmap on hydrogen standardization developed by the European Organization for Standardization (CEN/CENELEK) in 2023 [6].

Historically, the first attempts to standardize hydrogen date back to the beginning of the 20th century, when the scientific community first began to talk about standardization in hydrogen energy and, accordingly, about the need to create uniform requirements for hydrogen. Later, the Paris Climate Agreement 2015, aimed at decarbonizing the global economy, became an incentive for the development of hydrogen standardization. The development of alternative types of energy, including hydrogen, plays a key role in this process.

Today, the efforts of the international community are focused on the development of standards for hydrogen and its use, on the one hand, and attempts are being made to standardize hydrogen infrastructure on the other. An example is the flagship TransHyDE project, implemented since 2021 in Germany with the support of the German Federal Ministry of Education and Research, which aims to support the transportation, distribution and storage of hydrogen and other chemical energy carriers in practice.

III. Results

Within the framework of this study, it seems useful to look at who is involved in the development of standards for hydrogen and hydrogen infrastructure at the international and regional level. On a global scale, two major standardization organizations should be singled out here – the International Organization for Standardization (ISO) and the European Organization for Standardization (CENCENELEK). Statistics on the development of standards for hydrogen and hydrogen infrastructure at the international and regional level are presented in Table 1.

Table 1: *Development of hydrogen standards*

Organization	All Standard	Standards for Hydrogen pipeline
ISO	177 standards	1 standard
CEN	150 standards	1 standard

As can be seen from the analysis, a fairly broad regulatory framework for hydrogen energy has been developed on a global scale, but very little attention is paid to the standardization of hydrogen. Especially in terms of pipelines for hydrogen. The results in this direction have been achieved in Russia, where, in the course of the implementation of the national standardization program, new standards for steel pipes and cylinders for the transportation and storage of hydrogen were developed. The developer of a series of standards, consisting of three documents and establishing requirements for the transportation of hydrogen through steel and seamless pipes and for the storage of hydrogen in cylinders, is the technical committee TC 357 "Steel and cast iron pipes and cylinders". The standards are based on the results of research on overcoming hydrogen embrittlement, the destruction of metals, in particular, high-strength steel, when interacting with hydrogen. Moreover, Russia has created a series of products for the creation of pipelines for hydrogen - Sputnik H, which includes pipes for the production and distribution, transportation and storage of hydrogen.

The current situation suggests the need to intensify efforts in this direction in order to really reduce the cost of transporting hydrogen and thereby increase trade in hydrogen.

The largest number of standards has been developed in the International Organization for Standardization, but this fact does not mean that the harmonization of standardization in this area at the global level has been achieved. The fact is that the regulations for the adoption of ISO standards at the national level provide for three options: standards identical to ISO, standards modified, standards not equivalent to ISO. An analysis of the distribution of ISO adoption of hydrogen standards in different countries is presented in table 2.

Table 2: *Types of adaptation of standards for hydrogen*

Country	Type of adopted standards		
	Identical (IDT)	Modified (MOD)	Nonequivalent (NEQ)
Europe	+		
China and Kazakhstan	+	+	+
Gulf countries	+	+	
USA	+	+	
Russia	+		

If the standard is accepted as identical, it means that no changes have been made to the text of the document. In the case of adopting a standard as a modified one, the structure of the international standard is retained in the national standard, but the text of the document contains technical deviations that must be explained and justified. A non-equivalent standard differs from a modified standard in that the technical changes to the text are not explained.

Thus, when adopting ISO International Standards, countries are left with the opportunity to make significant changes to the requirements contained in the document without justification. This practice is actively used by China, where 6 standards for hydrogen pipelines have been developed, based on ISO international standards [1].

IV. Discussion

I. Key standards at the global level have not been developed

A key obstacle faced by standards developers is the difficulty of developing global international standards that take into account the diverse technical and legal requirements that are present in national legislations of different countries. From the analysis of standards for transporting hydrogen through pipelines it is clear that foreign technology for transporting hydrogen through pipelines is actively developing. At the global level a number of standards or guidelines have been formed covering the design, construction, operation, and maintenance of hydrogen pipelines. However, the existing standards for hydrogen pipelines mainly apply to gas pipelines and industrial pipelines, but since the transportation through pipelines has different characteristics, it is not fully applicable to hydrogen pipelines. Therefore, the existing documents require a significant revision.

The positive effect of the development of standards for hydrogen pipelines at the global level is that the efforts of international organizations allow many countries to form their regulatory legal system taking into account the safety requirements established in the international arena, the criteria for assessing efficiency, and the features of the conceptual apparatus. The solution to the problem of the difference in requirements contained in regulatory documents is to organize a dialogue among all stakeholders in global standardization in the field of hydrogen pipelines. The platform for such dialogue is Working Party on Regulatory Cooperation and Standardization Policies (WP.6) of UNECE.

II. Standards as the basis for the safety of hydrogen pipelines

The creation of a safe hydrogen infrastructure consists of three essential elements: standards themselves, certification schemes and labeling. The interaction of these elements is shown in Figure 1.

Figure 1: *Steps to ensure the safety of hydrogen pipelines*

Standards are therefore only the first step towards safety. The second important element is the certification of hydrogen pipelines - certification. Today, the difficulty lies in the fact that mainly developments in the field of certification relate to the reconstruction of existing networks for the transportation of hydrogen. An example of certification of existing pipelines for the transport of hydrogen is the program developed by the German certification body TUV-Sud entitled "Assessment of the suitability of new high-pressure gas pipelines for hydrogen operation (H2-ready certificate)", which aims to verify the suitability of existing pipelines. However, a comprehensive approach to the certification of hydrogen pipelines requires an analysis not only of existing networks, but also of the possibility of constructing new pipelines specifically for hydrogen. At the current stage, it is necessary to coordinate the efforts of the world community in this direction. The development of really working certification systems for hydrogen pipelines will make it possible to move on to the last step towards the creation of a safe hydrogen pipeline - the development of requirements for labeling hydrogen pipelines. The prospects for the implementation of this task in view of the great interest of both state bodies and the scientific community in the problem seem to be quite realizable.

Abstract

The transition to sustainable development in key industrial sectors presents both opportunities and challenges. On the one hand, adopting sustainable practices can lead to significant economic benefits, such as increased resource efficiency, cost savings in energy consumption, and access to new markets driven by growing demand for environmentally responsible products. Industries that prioritize sustainability also become more resilient to climate-related risks, including supply chain disruptions and regulatory changes aimed at reducing carbon emissions. Moreover, sustainable development fosters innovation, creating new business models and driving technological advancements. On the other hand, this transition carries inherent economic risks. High upfront investments in green technologies, infrastructure, and process transformations can be prohibitive for companies, especially in sectors with low profit margins. Additionally, the uncertainty surrounding evolving environmental regulations and market demands may cause disruptions to established business operations. Industries like energy, agriculture, and transportation face significant challenges in balancing short-term financial pressures with the long-term advantages of sustainability. This paper analyzes the economic benefits and risks associated with transitioning to sustainable development in these key sectors, focusing on how innovation, supportive policy frameworks, and financial incentives can help mitigate risks and promote long-term economic gains. It aims to provide insights into the strategies that industries and policymakers can adopt to ensure a smoother, more economically viable shift towards sustainability.

Keywords: sustainable development, industrial sectors, economic benefits, economic risks, climate resilience

I. Introduction

The global shift towards sustainable development has become a crucial priority for governments, businesses, and industries alike, as the impacts of climate change, resource depletion, and environmental degradation intensify. Key industrial sectors, including energy, agriculture, and transportation, are under growing pressure to adopt sustainable practices that minimize their environmental footprint while remaining economically viable. This transition is driven by a combination of regulatory mandates, market forces, and societal expectations for environmentally responsible production and consumption.

The benefits of moving towards sustainability are clear: enhanced resource efficiency, reduced operational costs, and new opportunities for innovation and growth. Companies that integrate sustainable practices can access emerging green markets, improve their brand reputation, and strengthen resilience against climate-related risks such as supply chain disruptions and stricter environmental regulations. Moreover, the increasing global focus on reducing carbon emissions has created incentives for industries to invest in renewable energy, waste reduction, and circular economy models.

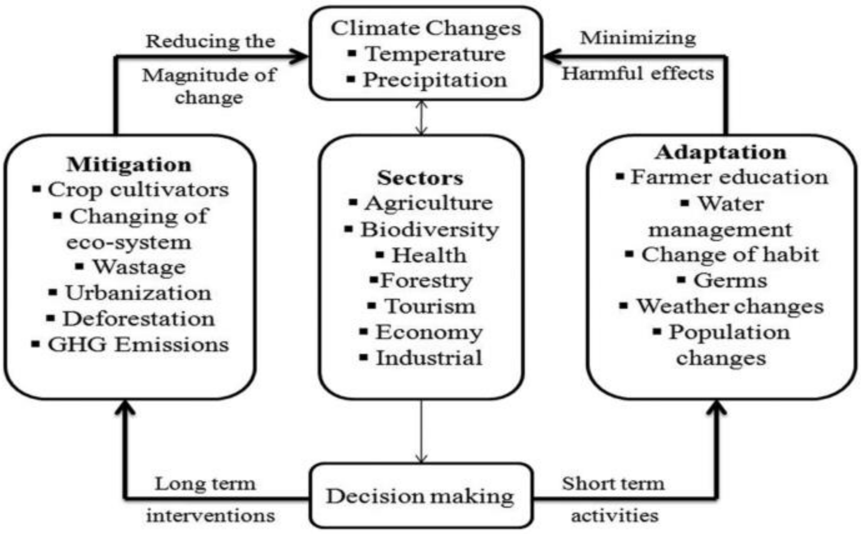

Figure 1: *Sectoral impacts of climate change with adaptation and mitigation measures*

Researchers express significant concern regarding the methodologies for adaptation and mitigation within various sectoral and geographical contexts. Key sectors that require focused adaptation and mitigation policies include agriculture, industry, forestry, transport, and land use. It is essential to address adaptation and mitigation efforts at both national and international levels. In recent decades, the world has grappled with the pressing issue of climate change, making it imperative to adapt to its effects for sustainable economic and social development. To effectively address climate change (CC), there is a need to formulate comprehensive policies and strategies on an international scale. Figure 1 illustrates current studies related to the sectoral impacts of climate change, along with corresponding adaptation and mitigation measures implemented globally.

However, the path to sustainable development is not without risks. High initial investment costs, uncertainty surrounding future regulations, and the potential for market disruptions pose significant challenges, particularly for industries that rely heavily on traditional, carbon-intensive processes. For many businesses, the question of how to balance short-term economic pressures with the long-term advantages of sustainability remains a critical concern.

This paper explores the economic benefits and risks of transitioning to sustainable development across key industrial sectors, focusing on how innovation, regulatory frameworks, and financial incentives can mitigate risks and promote long-term economic sustainability. By examining the complex dynamics at play, this research aims to provide a comprehensive understanding of the economic implications of this transition and offer insights into strategies for navigating these challenges.

II. Methods

To explore the economic benefits and risks of transitioning to sustainable development in key industrial sectors, this study employs a mixed-methods approach, combining quantitative data analysis with qualitative insights from case studies and expert interviews. The following methods were used to structure the research:

- Literature Review:

A comprehensive review of existing academic literature, industry reports, and policy papers was conducted to identify the current state of research on sustainable development in industrial sectors such as energy, agriculture, and transportation. This review helped define key concepts, challenges, and opportunities, providing a theoretical foundation for the study.

- Quantitative Analysis:

Data on investment trends, operational costs, and economic performance in industries transitioning to sustainable practices were collected from global databases, industry reports, and financial records. Key metrics analyzed included resource efficiency gains, cost reductions, and return on investment (ROI) in sustainable technologies, compared to traditional methods. Additionally, climate-related risks and financial impacts (e.g., insurance costs, supply chain disruptions) were quantified to assess the economic risks of inaction.

- Case Studies:

Detailed case studies of companies and sectors that have undergone successful transitions to sustainability were conducted to provide real-world examples of how economic benefits and risks manifest in practice. These case studies focused on leading firms in energy (e.g., renewable energy investments), agriculture (e.g., sustainable farming practices), and transportation (e.g., electric vehicle adoption), examining the strategies and outcomes of their sustainable initiatives.

- Expert Interviews:

Semi-structured interviews were conducted with industry experts, policymakers, and sustainability consultants to gather qualitative insights into the challenges and opportunities of transitioning to sustainable development. These interviews provided contextual understanding of the economic factors influencing decision-making, the role of policy, and the financial incentives that can mitigate risks in different sectors.

- Comparative Sector Analysis:

A comparative analysis across sectors (energy, agriculture, transportation) was performed to identify common patterns, sector-specific challenges, and the unique risks each sector faces. This method allowed for a holistic understanding of the economic impacts of sustainability transitions, while also identifying key differences in strategies required for various industries.

By combining these methods, this study aims to present a robust analysis of the economic implications of transitioning to sustainable development, highlighting both the benefits and the risks across key industrial sectors. The findings offer actionable insights for policymakers, businesses, and investors seeking to navigate the complex landscape of sustainability.

III. Results

The transition to a green economy involves redefining economic models and policies to promote environmental sustainability while ensuring economic growth and social well-being. This shift requires adopting practices that reduce carbon emissions, conserve resources, and encourage the use of renewable energy. The goal of this transition is to strike a balance between economic development and ecological preservation.

The benefits of moving to a green economy are substantial and wide-ranging (Fig.1). Environmentally, it helps mitigate climate change, protect ecosystems, and preserve biodiversity. By decreasing reliance on fossil fuels and embracing renewable energy, carbon emissions are reduced, and the overall ecological footprint is minimized, creating a healthier planet for future generations.

Economically, the green transition offers significant advantages. It promotes innovation, leading to the development of sustainable technologies and practices, which, in turn, generate new employment opportunities. Green sectors such as renewable energy, eco-friendly construction, and waste management contribute to job creation, economic growth, and long-term prosperity.

Additionally, businesses benefit from enhanced resource efficiency and cost savings. Implementing energy-efficient technologies, adopting sustainable supply chain practices, and optimizing resource use can lower operational costs. By minimizing waste, improving energy use, and embracing circular economy principles, companies can significantly cut expenses while enhancing their competitive edge.

However, the transition to a green economy also carries risks that must be managed. Businesses may face high upfront costs related to adopting sustainable technologies, retraining employees, or retrofitting existing infrastructure. Careful planning, strategic decisions, and financial investment are required to overcome these initial hurdles. It's important to recognize that this transition is a long-term strategy, and sustainable policies and investments may take time to deliver profitable returns. For example, the construction of renewable energy infrastructure, such as wind farms and solar plants, demands significant upfront investment and planning. Yet, as these projects begin generating clean energy, they gradually become financially viable and deliver substantial returns over time.

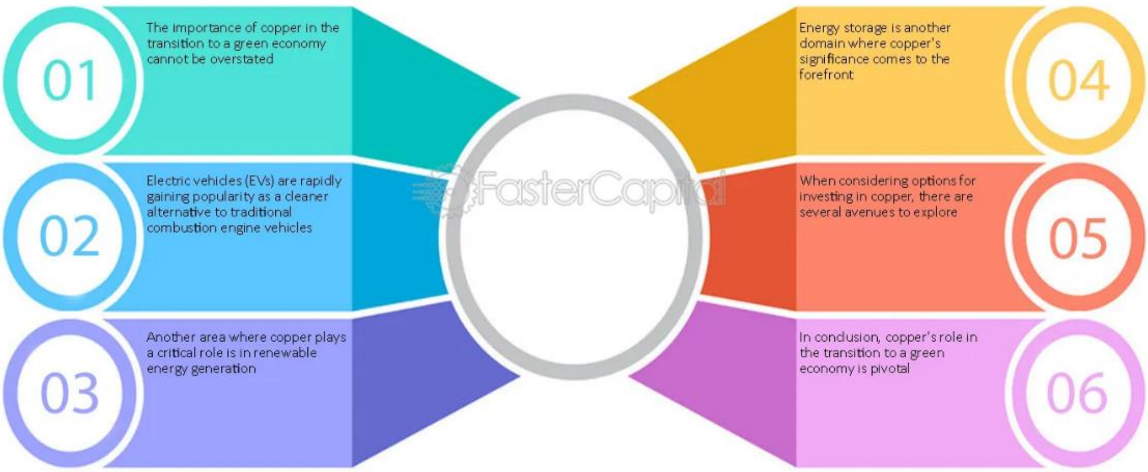

Figure 2: *Copper's Role in the Transition to a Green Economy*

The Crucial Role of Copper in the Green Economy Transition

The significance of copper in the shift toward a green economy cannot be overstated. As global attention increasingly turns to renewable energy sources and sustainable technologies, the demand for copper is anticipated to surge dramatically. This versatile metal is essential in a variety of green technologies, including electric vehicles (EVs), solar panels, wind turbines, and energy storage systems. From a sustainability perspective, copper is an optimal material due to its high conductivity, durability, and recyclability. Additionally, its antimicrobial properties make it particularly valuable for applications in healthcare and sanitation, especially in light of the ongoing COVID-19 pandemic.

The Growing Demand for Copper in Electric Vehicles

Electric vehicles are quickly becoming a cleaner alternative to traditional combustion engine vehicles. However, the transition to EVs necessitates a substantial increase in copper production. EVs require four times more copper than conventional vehicles, largely due to their electric motors, wiring, and charging infrastructure. With governments worldwide committing to phasing out the sale of new internal combustion engine vehicles in the coming decades, the demand for copper in the automotive sector is expected to rise significantly. Investing in copper now can yield long-term benefits as the EV market continues to expand.

Copper's Essential Role in Renewable Energy Generation

Copper is also vital in renewable energy generation, particularly in solar panels and wind turbines, which depend heavily on copper for electrical wiring and connections. The International Copper Association estimates that a single onshore wind turbine can contain up to four tons of copper, while large-scale solar farms can require hundreds of kilotons of copper for their infrastructure. As countries work to decrease their carbon footprints and increase their reliance on renewable energy sources, the demand for copper will inevitably grow. Investing in copper mining companies or copper exchange-traded funds (ETFs) can provide investors with valuable exposure to this expanding sector.

Copper's Importance in Energy Storage Solutions

Energy storage further highlights copper's significance. Batteries, essential for storing energy from renewable sources and ensuring a stable power supply, rely on copper for wiring and electrical connections. Lithium-ion batteries, commonly used in electric vehicles and renewable energy storage, contain a substantial amount of copper. Additionally, redox flow batteries, which offer scalable and efficient solutions for grid-scale energy storage, also incorporate copper in their design. As the demand for energy storage solutions rises, so will the need for copper. Investing in companies involved in battery manufacturing or copper mining can be a wise choice for long-term gains.

Investment Opportunities in Copper

When considering investment options in copper, several avenues are available. One approach is to invest directly in copper mining companies, providing exposure to the entire copper supply chain, from extraction to production. However, investing in individual mining firms carries risks related to geopolitical factors, labor disputes, and environmental concerns. An alternative is to invest in copper ETFs, which offer a diversified portfolio of copper mining companies, spreading risk across multiple entities and providing greater liquidity. Additionally, investing in renewable energy companies that significantly rely on copper can also be a practical strategy, as their success is closely linked to the demand for copper.

In summary, copper plays a pivotal role in the transition to a green economy. As the demand for renewable energy, electric vehicles, and energy storage solutions continues to grow, so too does the necessity for copper. Investing in this versatile metal presents a smart opportunity for long-term gains, as it is positioned to be a critical component of sustainable technologies. Whether through direct investments in copper mining companies, copper ETFs, or renewable energy firms, investors can strategically position themselves to benefit from the escalating demand for copper in the journey toward a greener future.

Additionally, companies must navigate regulatory risks as governments introduce policies to drive the green transition. Staying updated on evolving compliance requirements is critical, as non-compliance can result in fines, penalties, and reputational harm. By proactively aligning with environmental regulations and engaging in sustainability initiatives, businesses can reduce regulatory risks and show their commitment to responsible practices.

As we move toward a more sustainable future, the concept of a "green economy" has gained significant traction. A green economy is characterized by its low carbon emissions, resource efficiency, and social inclusivity. Its primary goals are to mitigate environmental risks, address ecological scarcities, and foster sustainable economic growth and social well-being. The advantages of a green economy are extensive and impactful, affecting our environment, economy, and society as a whole (Fig.3).

Job Creation

One of the most prominent benefits of a green economy is job creation. As we transition to more sustainable practices, the demand for labor in green industries—such as renewable energy, sustainable transportation, and eco-tourism—is set to rise significantly. The International Labour

Organization estimates that this transition could lead to the creation of up to **24 million new jobs globally by 2030**.

Economic Growth

A green economy has the potential to stimulate substantial economic growth. Research indicates that investments in green sectors can yield higher returns than traditional investments, and these sectors are expanding more rapidly than the overall economy. For instance, the renewable energy industry has experienced a **43% increase in employment since 2010**, while the broader economy has only grown by **3%** during the same period.

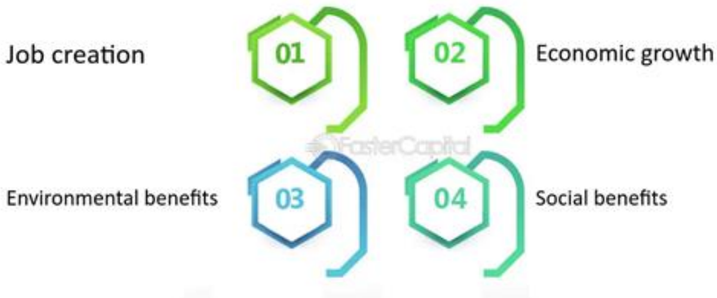

Figure 3: *Benefits of a Green Economy - Green Economy: Driving Economic Growth through the Green Economy*

Environmental Benefits

Transitioning to a green economy can significantly lessen our environmental impact. By prioritizing renewable energy sources and sustainable practices, we can reduce greenhouse gas emissions, enhance air and water quality, and protect biodiversity. For example, wind power generates **zero emissions** and requires minimal water, making it a much cleaner energy source compared to traditional fossil fuels.

Social Benefits

A green economy also offers considerable social benefits. Investments in sustainable infrastructure and public transportation can improve access to essential services and help mitigate social inequalities. For example, a green economy could enhance access to healthcare and education for low-income communities and provide greater availability of green spaces and recreational areas.

The benefits of a green economy are extensive and impactful, influencing our environment, economy, and society as a whole. By investing in green industries and sustainable practices, we can create new jobs, foster economic growth, reduce our environmental footprint, and enhance social well-being. Embracing a green economy is not just an environmental imperative; it is a pathway to a more prosperous and equitable future for all.

IV. Discussion

Understanding what a company's transition to a green economy truly entails is crucial, as it represents not only a global necessity but also a strategic opportunity for businesses. This transition involves embedding sustainability into a company's core strategies, supply chains, and operations. By adopting green practices, businesses can improve their brand image, appeal to environmentally conscious consumers, and gain a competitive edge in the marketplace.

In addition, transitioning to a green economy enhances operational efficiency by optimizing resource use, reducing waste, and incorporating renewable energy. These initiatives lead to significant cost savings, increased profitability, and greater resilience to fluctuations in resource prices.

The European Union (EU) serves as a model of progress in the green economy transition, with its strong commitment to sustainable development. The EU has made substantial strides in adopting renewable energy, implementing energy efficiency measures, and embracing circular economy principles. These efforts have not only minimized environmental impacts but also enhanced energy security by reducing reliance on fossil fuel imports. As a result, the transition has improved air quality, public health, and the overall well-being of the population.

Moreover, the EU has positioned itself as a global leader in sustainable innovation and technology. European companies have pioneered cutting-edge solutions in areas such as renewable energy, energy storage, sustainable mobility, and circular economy practices. The supportive ecosystem for green businesses within the EU has fostered collaboration, research, and development, driving economic growth and boosting competitiveness on a global scale.

For the full benefits of the green economy transition to be realized, cooperation between businesses and policymakers is essential. Governments can support this process through policies, incentives, and funding, helping to reduce risks for companies. Measures such as tax incentives, grants, and subsidies for green investments, along with regulatory frameworks that promote sustainable practices, are critical to facilitating this transition.

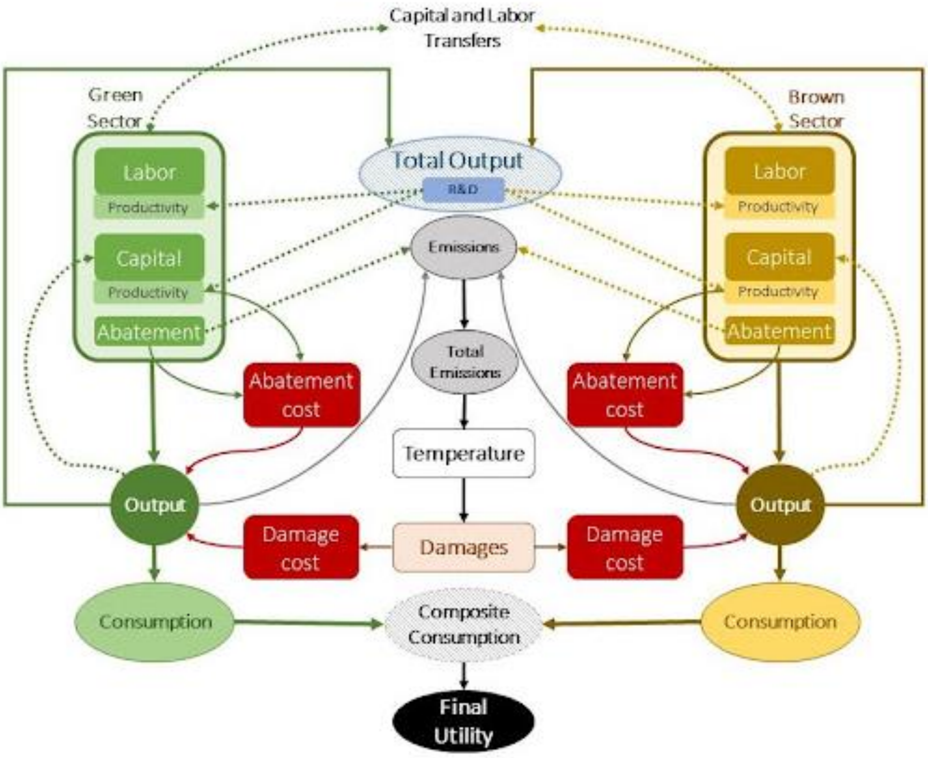

Figure 4: *Transitioning to a green economy*

A widely accepted viewpoint, supported by scientists, policymakers, and the general public, emphasizes the need for an integrated approach to addressing the climate crisis and advancing sustainable development. Achieving a transition to a green global economy while sustaining economic growth will require significant alterations in the frameworks of global production and consumption (fig.4). However, the precise mechanisms of resource reallocation—specifically, how and where these changes should take place—depend heavily on the underlying assumptions regarding the speed of the green transition.

Businesses, on the other hand, must develop a comprehensive strategy that includes sustainable practices, stakeholder engagement, and continuous innovation. This involves assessing current operations, setting ambitious sustainability targets, and investing in research and development of green technologies. Collaboration with suppliers, customers, and industry peers is vital to driving collective action and building a sustainable value chain.

Furthermore, companies should integrate sustainable principles throughout their entire operation. This includes sourcing materials responsibly, adopting energy-efficient manufacturing processes, reducing waste and promoting recycling, and managing supply chains with sustainability in mind. By taking a holistic approach to sustainability, businesses can ensure their long-term viability and resilience in a rapidly evolving green economy.

In addition to the strategies mentioned earlier, sustainability reporting plays a crucial role in helping companies transition successfully to a green economy. It provides a structured framework for businesses to measure, monitor, and communicate their environmental, social, and governance (ESG) performance to stakeholders. This process is essential for ensuring transparency, accountability, and continuous improvement in sustainability practices.

By adopting robust sustainability reporting practices, companies can gain a clear understanding of their environmental impacts, resource usage, and social responsibilities. This enables them to identify areas where they can improve, set meaningful targets, and monitor their progress over time. Transparent reporting also allows stakeholders—including investors, customers, employees, and communities—to assess a company's commitment to sustainability and make more informed decisions based on this information.

Moreover, sustainability reporting promotes accountability by encouraging companies to disclose their ESG performance and showcase their efforts in reducing environmental footprints, promoting social equity, and upholding good governance practices. This can enhance a company’s reputation, build trust with stakeholders, and attract both socially responsible investors and environmentally conscious customers.

Sustainability reporting also serves as a platform for sharing best practices, lessons learned, and innovative solutions within industries. This promotes collaboration among peers and encourages the exchange of knowledge, accelerating the collective transition to a green economy. By openly sharing successes and challenges, companies can inspire others, contribute to sector-wide improvements, and help drive broader sustainability goals.

In the context of the green economy transition, sustainability reporting becomes an essential tool for businesses to communicate their progress in aligning with sustainability objectives, reducing their environmental impacts, and embracing greener practices. It allows companies to demonstrate their contribution to the green economy and their commitment to long-term environmental stewardship. Furthermore, as investors, regulators, and consumers increasingly demand transparency and accountability in business practices, sustainability reporting enables companies to meet these expectations effectively.

Thus, sustainability reporting is a vital component of any company's journey towards a green economy. It provides a clear framework for measuring and communicating ESG performance, fostering accountability, transparency, and ongoing improvement. By integrating sustainability reporting into their operations, businesses can navigate the complexities of the green economy transition, gain stakeholder trust, and contribute meaningfully to a more sustainable future.

In conclusion, the transition to a green economy offers numerous benefits for businesses, society, and the environment. Shifting to sustainable practices not only helps mitigate environmental impacts but also drives economic growth, innovation, and job creation. While there are risks and challenges involved in this transition, proactive businesses can address these risks through careful planning, compliance with regulations, and engagement with stakeholders. At the same time, it is critical for policymakers to create supportive frameworks that encourage businesses to pursue sustainability and contribute to a more sustainable future.

Abstract

The article presents the experimental data obtained using high-precision experimental devices on the density of the Gala-alti geothermal water of the Shabran region of Azerbaijan at high pressure and temperature.

Geothermal energy is a part of alternative energy and is widely used for various purposes all over the world. In recent years, due to the increase in the cost of traditional energy sources and their possible shortage in the future, technologies using thermal waters are being actively developed. In order to use geothermal waters in various power plants, it is necessary to know their thermophysical properties. Geothermal waters in Azerbaijan were studied in the 20th century [1-5]. Most of these studies are related to geological analysis and chemical structure analysis of geothermal waters. In order to study the methods of using geothermal waters and obtaining energy from them, it is necessary to study their thermal-physical properties. This article presents experimental data about the "Gala-alti" geothermal water in the Shabran region of Azerbaijan.

In order to measure the density of the "Gala-alti" geothermal water of Shabran region at high pressure and temperature, a high-precision experimental device using the vibration-tube densimeter method was used [6]. This method for modern experimental thermal physics is characterized by high measurement accuracy, simplicity, insignificant time and economic costs, as well as the possibility of automation of the measurement process. The working principle of the experimental device is given in [7-9]. The main element of the Anton-Paar DMA HPM vibrating tube densimeter unit is a measuring cell consisting of a Hastelloy C-276 vibrating tube made of nickel-based stainless steel alloys with high corrosion resistance. The measuring element is designed to measure temperature in the range T=263.15-473.15 K and pressure p=0.1-140 MPa. The temperature in the measuring chamber containing the U-shaped tube is maintained using an external thermostat F32-ME (Julabo, Germany) with an error of 0.01 K. Temperature is measured using a platinum resistance thermometer (ITS-90).) Pt100 (Type 2141) with an error of ±15 mK. The pressure is generated using a HIP pump (No. 37-6-30, USA) and pressure sensors (WIKA Alexander Wiegand GmbH & Co., Germany) using P-10 accuracy class 0.1% and HP-1 accuracy class 0.5% is measured by The signals from the pressure gauges are also transmitted to the computer control system. In these conditions, the error in density measurement was $\Delta\rho/\rho = \pm(0.01 - 0.03)\%$*. (p, ρ,T) dependences were measured using isotherms from the minimum possible pressure for a given temperature and then increasing it in increments of about 10 MPa. Researches were carried out in the range T=(274.15 - 413.15) K and pressures up to p=100 MPa. Densities obtained at atmospheric pressure were compared with those measured on the DSA 5000M. The data obtained by different methods are in good agreement with each other within* $\Delta p/\rho = \pm 0.02\%$*. The obtained results of density of "Gala-alti" geothermal water of Shabran region are shown in Table 1.*

For the measurement of the thermal physical properties of the Gala-alti geothermal water of the Shabran region of Azerbaijan, the methodologies that allow for very accurate measurements in

the liquid phase at high state parameters have been selected and substantiated. An experimental device was assembled and adjusted for measuring density at different temperatures and pressures using the vibrating tube densimeter method. In order to check the working capacity of the experimental unit, the densities of aqueous solutions of water, toluene, methanol, and NaCl as reference substances were studied in a wide range of state parameters.
Since the thermal-physical properties of the Gala-alti geothermal water of the Shabran region of Azerbaijan were studied for the first time, it is impossible to compare them with the literature data. The obtained data were compared with the thermal-physical properties of pure water and it was determined that similar anomalies of water in the behavior of the studied properties are known.

Keywords: geothermal water, density, experimental studies, thermal-physical properties, energy

I. Introduction

Geothermal energy is a part of alternative energy and is widely used for various purposes all over the world. In recent years, due to the increase in the cost of traditional energy sources and their possible shortage in the future, technologies using thermal waters are being actively developed. In order to use geothermal waters in various power plants, it is necessary to know their thermophysical properties. Geothermal waters in Azerbaijan were studied in the 20th century [1-5]. Most of these studies are related to geological analysis and chemical structure analysis of geothermal waters. In order to study the methods of using geothermal waters and obtaining energy from them, it is necessary to study their thermal-physical properties. This article presents experimental data about the "Gala-alti" geothermal water in the Shabran region of Azerbaijan.

II. Methods

In order to measure the density of the "Gala-alti" geothermal water of Shabran region at high pressure and temperature, a high-precision experimental device using the vibration-tube densimeter method was used [6]. This method for modern experimental thermal physics is characterized by high measurement accuracy, simplicity, insignificant time and economic costs, as well as the possibility of automation of the measurement process. The working principle of the experimental device is given in. The main element of the Anton-Paar DMA HPM vibrating tube densimeter unit is a measuring cell consisting of a Hastelloy C-276 vibrating tube made of nickel-based stainless steel alloys with high corrosion resistance. The measuring element is designed to measure temperature in the range T=263.15-473.15 K and pressure p=0.1-140 MPa. The temperature in the measuring chamber containing the U-shaped tube is maintained using an external thermostat F32-ME (Julabo, Germany) with an error of 0.01 K. Temperature is measured using a platinum resistance thermometer (ITS-90).) Pt100 (Type 2141) with an error of ±15 mK. The pressure is generated using a HIP pump (No. 37-6-30, USA) and pressure sensors (WIKA Alexander Wiegand GmbH & Co., Germany) using P-10 accuracy class 0.1% and HP-1 accuracy class 0.5% is measured by The signals from the pressure gauges are also transmitted to the computer control system. In these conditions, the error in density measurement was $\Delta\varrho/\varrho = \pm(0.01 - 0.03)\%$. (p, ρ,T) dependences were measured using isotherms from the minimum possible pressure for a given temperature and then increasing it in increments of about 10 MPa. Researches were carried out in the range T=(274.15 - 413.15) K and pressures up to p=100 MPa. Densities obtained at atmospheric pressure were compared with those measured on the DSA 5000M. The data obtained by different methods are in good agreement with each other within $\Delta p/\rho = \pm 0.02\%$. The obtained results of density of "Gala-alti" geothermal water of Shabran region are shown in Table 1.

49.936	1024.19	274.15	30.215	1011.95	293.18

The experimental data were generalized using the equation of state:

$$p = A \cdot \rho^2 + B \cdot \rho^8 + C \cdot \rho^{12} \tag{1}$$

Here the coefficients A(T), B(T) and C(T) in equation (1) are functions of temperature.

$$A(T) = \sum_{i=1}^{4} a_i T^i$$

$$B(T) = \sum_{i=0}^{3} b_i T^i \tag{2}$$

$$C(T) = \sum_{i=0}^{3} c_i T^i$$

The obtained coefficients ai, bi and ci in equation (2) are given in Table 2. Equations (1) - (2) describe well the experimental data on density of "Gala-alti" geothermal water in Shabran region.

Table 2: *Values of the coefficients a_i, b_i and c_i in equation (2)*

a_i	b_i	c_i
a_1 = -3.77278411	b_0 = 8820.374609	c_0 = -6716.43133642012
a_2 = 0.0103724374	b_1 = -72.493837104	c_1 = 57.00035877163
a_3 = $-0.1779354\cdot10^{-4}$	b_2 = 0.2129181614	c_2 = -0.16486118
a_4 = $0.2274616251\cdot10^{-7}$	b_3 = $-0.20544052\cdot10^{-3}$	c_3 = $0.15801767\cdot10^{-3}$

The errors are calculated using the following equations and are presented in Table 3.

Standard error:

$$STD = \sqrt{\frac{\sum(\rho_{exp} - \rho_{calc})^2}{n(n-1)}} \tag{3}$$

Absolute error:

$$ABD = \frac{1}{n}\sum\left|\rho_{exp} - \rho_{calc}\right| \tag{4}$$

Average percentage error:

$$APD = \frac{100}{n}\sum\left|\frac{\rho_{exp} - \rho_{calc}}{\rho_{exp}}\right| \tag{5}$$

where ρ_{exp} – experimental density values; ρ_{calc} –– density values calculated using the equation of state; n – number of experimental data.

Table 3: *Error values of equation (1)*

Average percentage error	Standard error	Absolute error
0.0097	0.142	0.12

The density of the geothermal water "Gala-Alti" of the Shabran district at atmospheric pressure was also measured using the DSA 5000M installation, which allows measurements to be taken at atmospheric pressure and temperatures up to 363.15 K with an accuracy of 0.01% (more accurate measurements than at high pressures).

Based on the equation of state, the following thermophysical properties were calculated:

- isothermal compressibility coefficient

$$\kappa_T = 1/[2A(T)\rho^2 + 8B(T)\rho^8 + 12C(T)\rho^{12}] \tag{6}$$

- isobaric coefficient of thermal expansion

$$\alpha_p = (1/\rho)(\partial p/\partial T)_\rho (\partial p/\partial \rho)_T^{-1} \tag{7}$$

$$\alpha_p = \frac{A'(T) + B'(T)\rho^6 + C'(T)\rho^{10}}{2A(T) + 8B(T)\rho^6 + 12C(T)\rho^{10}} \tag{8}$$

where A', B' and C' derivatives of coefficients A, B and C of the equation of state defined by the following formula:

$$A(T)=\sum_{i=1}^{3}a_iT^i,\ B(T)=\sum_{i=0}^{2}b_iT^i,\ C(T)=\sum_{i=0}^{2}c_iT^i. \quad (9)$$

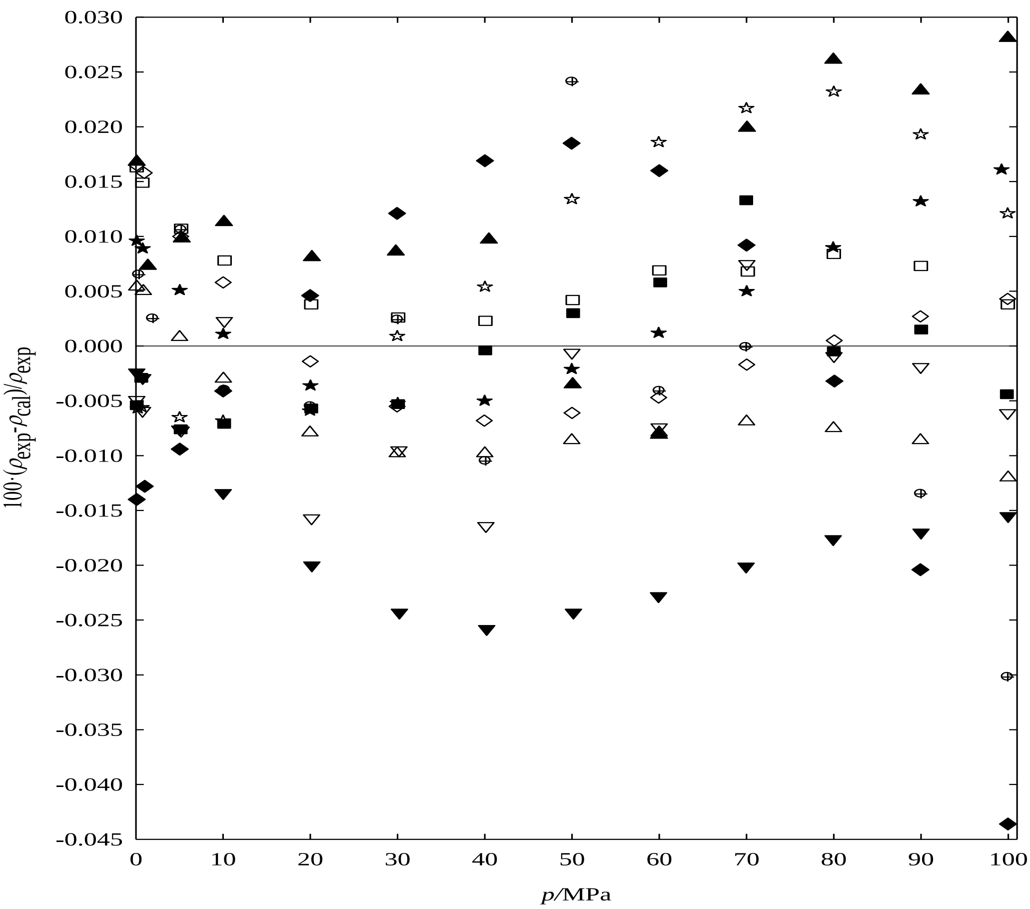

Figure 1: *Dependence of the pressure p on the pressure p of the density of the experimentally measured density of the Gala-alti thermal water of the Shabran region of Azerbaijan and the density ρ_{cal} calculated with the help of the equation of state $\rho_{exp.}$ ◆, 274.15 K; ■, 278.12 K; ▲, 283.21 K; ▼, 293.18 K; ★, 298.15 K; ◇, 313.15 K; □, 333.15 K; △, 353.15 K; ▽, 373.16 K; ☆, 393.15 K; ⊕, 413.15 K.*

III. Results

For the measurement of the thermal physical properties of the Gala-alti geothermal water of the Shabran region of Azerbaijan, the methodologies that allow for very accurate measurements in the liquid phase at high state parameters have been selected and substantiated. An experimental device was assembled and adjusted for measuring density at different temperatures and pressures using the vibrating tube densimeter method. In order to check the working capacity of the experimental unit, the densities of aqueous solutions of water, toluene, methanol, and NaCl as reference substances were studied in a wide range of state parameters.

IV. Discussion

Since the thermal-physical properties of the Gala-alti geothermal water of the Shabran region of Azerbaijan were studied for the first time, it is impossible to compare them with the literature data. The obtained data were compared with the thermal-physical properties of pure water and it was determined that similar anomalies of water in the behavior of the studied properties are known.

Abstract

Undoubtedly, almost every entrepreneur in the process of doing business faces various risks, the severity of which depends on many factors. In particular, the entrepreneur's ability to predict and evaluate certain events on time, competently select business partners, calculate the financial return from the project, and, of course, respond to the current situation as quickly as possible and give a rational solution in the interests of business. At the same time, in our opinion, entrepreneurial activity, in any case, is still accompanied by a number of unexpected events that are almost impossible to predict accurately. In connection with it, there always exist risks of failure and partial or complete loss of profit. This and many other factors increase the relevance of the chosen topic of our research, in which we reveal the essence of risks, their main types, and also suggest ways to reduce them through the use of generally accepted methods to deal with them.

Keywords: entrepreneurship, entrepreneurial risks, economics, risk, hedging, diversification, insurance, limitation

I. Introduction

Undoubtedly, in the course of its entrepreneurial activity practically each organization faces a large number of different risks that require urgent solutions.

It is important to understand that risks have different origin, ranging from the factors of their occurrence to the scale of negative consequences. That is, risk situations can occur in absolutely any field of activity. As an example, we can consider a situation where a supplier violates the terms of delivery of goods, turning out to be a scammer, and leaves the customer both without money and an order. Another example is the incompetence of a new employee in solving standard issues related to his position. These and many other examples clearly illustrate and confirm the fact that entrepreneurs face risks at absolutely any stage of running business. Also, an important place in our lives is occupied by risks from the external environment, such as natural hazards, economic crises, natural disasters and many more. All of the above can play a decisive role in the activities of enterprises and lead the organization to bankruptcy. In this connection, the importance of such a phenomenon as risk management, is increasing as it is a certain system for managing risks and relationships that arise in the process of managing them.

That is why the task of all enterprises is to seriously focus on the quality of risk management and the search for effective anti-crisis ways to manage them.

So, what is a risk? Economists interpret this term from the point of view of probable damage, failure due to the fact that the result is very ambiguous.

As the world practice of many countries shows, underestimating economic risks when developing business tactics and strategies has a very negative impact on the development of society, leading the country's economy to stagnation.

Unfortunately, many enterprises, even now, in the era of the 21st century, underestimate the importance of holding events that reduce the management risks of running business.

In our opinion, it is almost impossible to completely avoid risks, but it is always possible and necessary to try to find ways to reduce them.

Thus, it is very important to understand the margin between justified and unjustified risk in each situation.

II. Methods

Undoubtedly, the topic of our research is very relevant.

First of all, this is due to the fact that entrepreneurial activity is interpreted from the point of view of an independent direction, carried out at your own risk, and aimed at systematically making a profit from the activities performed.

In this connection, the relevance of the issue of entrepreneurial risk management is increasing every day.

The main aim of our research is to study the essence and role of entrepreneurial risks for the economic activity of enterprises.

The object of our research is entrepreneurial risks. And the subject is to find ways to reduce the risks under consideration.

In the course of writing this scientific paper, we studied the works of both domestic and foreign economists, periodical articles, textbooks, teaching aids, and Internet resources devoted to the topic of our research.

III. Results

As practice shows, even in leading industrial powers, risk management as a separate science has appeared quite recently. The term risk management was first mentioned in the American economic publication Harvard Business Review in 1956. It was then that the idea of hiring an employee as a risk manager to reduce production losses appeared. In addition, discussions about risks began since 1950, using mathematical research methods. A clear confirmation is the use of probability theory techniques to predict certain steps of organizations when faced with various situations. Thus, due to the increasing instability of the economic situation because of the oil crisis of 1973, the need for risk assessment measures has increased. After this, risk assessment became widespread in business, especially in the United States. That is, since the 1970s, the first consulting companies appeared, which, first of all, were engaged in assessing the risks of various foreign markets with studying the economic instability of certain countries in order to identify their influence on large Western corporations. It should be noted that the first qualification certificates in risk management were also issued in the USA back in 1973.

Let`s also note, that in 1975 the name of the organization, previously known as the American Society of Insurance Management, was changed to the Risk and Insurance Management Society, which has the abbreviation RIMS. Many industrial corporations began actively buying futures contracts in foreign currencies, using them as a kind of risk management tool. Many economists believe that the desire of companies to protect themselves from financial market instability has been an auxiliary tool that has served the development of investment capital since the 1970s.

At the same time, it should be noted that in those days industrial corporations did not open special risk management departments. A clear proof of the above idea is a survey of relevant corporations conducted in 1973, in which only 25% of respondents announced the presence of their own risk assessment units, and only 10% of respondents reported the use of consulting agencies. A similar survey was also conducted in 1975, which again confirmed the unpreparedness of transnational corporations to develop full-fledged approaches to assess the political stability of their foreign markets.

At the same time, banks pursued a more active policy. In particular, in 1975 in the USA, Chase Manhattan Bank created a special country risk committee. Furthermore, we`d like to note that by 1970 the term risk management hadn't been commonly used yet. That is, to solve certain problems and assess risks, top managers turned to various organizations, government officials, scientists, etc. It is important to note that all this had a chaotic origin, since there was no clearly formed scheme for fighting risks. As world practice shows, risk management methods in industrial companies began to develop rapidly in the last decades of the twentieth century.

Risk management methods were used more actively in certain complex industries, in particular in transport, energy, oil production, etc. It was connected with the fact that these areas required more detailed analysis due to technological difficulties and safety requirements.

This is how the rapid development of risk management begins.

Thus, the process of risk management in a simplified form includes 4 main stages:

1. The process of risk identification, the essence of which is to identify and predict certain risks in a particular sphere of activity;
2. Carrying-out risk analysis, the essence of which is to determine the probability of a particular event occurrence, as well as to assess the possible amount of potential damage;
3. Risk mitigation through the development of certain measures aimed at preventing possible risk events, and in case they occur then the measures to eliminate the consequences are developed;
4. Carrying-out control measures aimed at managing and resolving issues related to existing risks, with the development of preventive maintenance work, the main purpose of which is to eliminate certain risks in the future, or to minimize their impact in the future.

IV. Discussion

Now we would like to consider the main types of entrepreneurial risks, which are classified into three types according to their consequences:

- ✓ Acceptable risks;
- ✓ Critical risks;
- ✓ Catastrophe risks.

Let's consider each type in detail.

Let's start with the acceptable risks. The essence of such risks lies in the fact that in this case, the losses of enterprises are much less than the projected profit.

For example, let`s consider the following situation: the owner of a car repair shop ordered a certain lot of spare parts, which did not reach the customer intact, and therefore the owner suffered losses because he had to reorder it.

But despite this fact, the situation is revealed in the context of acceptable risks, since the losses of the enterprise turned out to be less than its monthly profit.

As for critical risks, they occur in the case of significant expenses that exceed the expected profit.

This may be accompanied by the fact that the money invested in the business may not be repayable.

An example is a faulty lot of all goods, which was supposed to bring a monthly profit.

And finally, the last type of risk, known as catastrophe risk, is characterized by the fact that it can lead the enterprise to a complete loss of property or capital –closure or bankruptcy.

For example, an entrepreneur decided to open a takeaway business and invested about two million rubles in this area, expecting cover its cost within the first six months.

But, unfortunately, the circumstances were not the best, as there was a fire in the organization, which led to the loss of all property.

Accordingly, for the full restoring of all losses, considerable financial investments are needed again, but the entrepreneur no longer has them.

Therefore, the enterprise is heading towards bankruptcy. This is interpreted as a catastrophe.

Thus, having considered the classification of risks according to the scale of their consequences, we would also like to highlight two generally accepted reasons for their occurrence:

- ✓ External;
- ✓ Internal.

External risks, as a rule, cover all factors of the external environment, in particular, economic instability in the country, various natural disasters, emergencies, changes in the legislative framework, etc.

Internal risks are associated with changes in the internal environment of the enterprise. In particular, faulty calculations, selection of personnel, violation of delivery time, problems with product quality, shortage of raw materials, etc.

Considering the topic of risks, the following questions arise: “How to minimize risks”? “What methods are practiced at the present stage of economic development”? Let's try to answer these questions.

In our opinion, it is quite possible to avoid the negative consequences of risks through timely making the most effective and rational decisions on identification and assessment of risks.

This requires a continuous analysis of the companies’ activities, examining all transactions and their conditions, external factors, and, in general, the entire financial condition of the company.

In the economic environment, it is common to distinguish four main methods aimed at minimizing risks, including:

- ✓ Insurance;
- ✓ Hedging;
- ✓ Diversification;
- ✓ Limitation.

Let's consider the essence of each tool in detail.

As for the insurance method, it is necessary to understand the possibility and desire of an entrepreneur to insure his property, equipment, loss of income, expenses due to failures of obligations of suppliers of goods, bankruptcy, liability to third parties etc.

This is done in order to obtain compensation or full coverage of all expenses of the organization from the insurance company.

As for hedging, its essence is to protect enterprises from price risks.

As an example, we can consider the situation of an individual entrepreneur signing a contract for the supply of certain spare parts at a fixed price throughout the year.

An important place is also given to diversification, the main task of which is to increase the efficiency of entrepreneurial activity by redistributing risks.

At the same time, diversification pursues the following most important goals:

- ✓ Finding a competitive advantage;
- ✓ Increasing the profitability of production;
- ✓ Reducing the probability of enterprise bankruptcy.

An example of diversification is the opening of a new business by an entrepreneur with minimal investment, since the current business does not yet have a wide possibility, which does not exempt the entrepreneur from paying salaries to employees and rent.

Therefore, the entrepreneur decides to open another source of income in the same premises.

And finally, limiting, which is responsible for setting limits and restrictions on the amount of expenses, loans or investments.

In addition, we would like to focus on the state of risk management in foreign infrastructure companies.

Let's look at the Table below.

Table 1: *The state of risk management in foreign infrastructure companies*

Criterion	BC Hydro, Canada	Chubu Electric Power, Japan	Nothern powergrid, United Kingdom	Pacific Gas and Electric Company, USA	National grid, United Kingdom and USA
Having a risk manager position or a corresponding organization department	The responsibilities of the company's CEO include identifying risks, informing the board of directors and managing risks.	The functions of the corporate planning and strategy department include identifying the most important risks and formulating a risk management plan for functional units	-	Vice President responsible for risk and audit	A special risk management team has been created. In addition, the responsibility of the board of directors includes the risk management and internal control system
Availability and completeness of information on risks in reporting to shareholders	+	+	+	+	+
Availability of a corporate risk management system	+	+	+	+	+
Operational risk management within the risk management system	+	-	+	+	+
Comment	The functions of all committees created by the board of directors (audit and finance, capital projects, safety, human resources and environment, etc.) include identifying and managing relevant risks in the area of activity	The functions of all committees created by the board of directors (audit and finance, capital projects, safety, human resources and environment, etc.) include identifying and managing relevant risks in the area of activity	Every year, the effectiveness of the risk management system is reviewed at the level of the company's president and CEO and is confirmed by a corporate certificate	The functions of committees created by the board of directors include: – control over risk management (finance committee); – control over the practices used on risk management (committee on nuclear energy,	The functions of all committees created under the auspices of the board of directors (audit, finance, safety, environment and health, executive committee) include risk management. The effectiveness of the risk management system is reviewed annually by the board of

				operations and safety)	directors

V. Conclusions

Thus, as world practice shows, risk management is gradually becoming an independent type of professional activity, the importance of which is increasing daily. As it was mentioned above, risk acts as an integral part of the entrepreneurial activity of any economic entity. In this regard, the knowledge of risks, factors that influence its significance, ways to fight them, most of which are foreign in origin, serve as the very tool that increases the efficiency of entrepreneurial activity. A very important place is given to the ability to respond quickly and promptly to force majeure circumstances, and search for the most effective method for a particular case to protect against risk situations. Thus, we can conclude that risk management issues play a very important role for all entrepreneurs.

TAXES AS A TOOL TO ENSURE ENVIRONMENTAL SAFETY

Larisa Aguzarova, Fatima Aguzarova, Kamilla Tsallaeva

aguzarova.larisa@yandex.ru
aguzarus@yandex.ru
kamilla.tsallaeva@yandex.ru

Abstract

In this paper, taxes and fees are considered as a means of regulating the environment, ecological state. The experience of ensuring environmental safety through taxation is described. The authors consider the shortcomings and disadvantages existing in the Russian tax system and environmental problems within the country. The results of taxation system analyses are given and systemized. In the paper the authors outline proposals and ideas for environmental protection using tax instruments.

Keywords: taxes, environmental safety, tax regulation, environmental protection

I. Introduction

At the present stage of development of all human activity spheres, inexorable processes are taking place to change the environment. The human impact on the environment condition is getting more intense every day. As a result of human activity, environmental pollution occurs, the depletion of natural resources and the gradual destruction of flora and fauna (for example, transport greatly pollutes the environment with exhaust gases when moving). That is why the state policy in the field of economic development and the ecological state of the environment should be interconnected.

Within the implementation of measures for the economic regulation of the environment, taxes act as a key tool to minimize the damage that is caused to the environment in the course of economic activity.

The use of exhaustible natural resources is conditioned by the need of mankind to be provided comfortable living. Today, the desire for high standards of living is associated with the depletion of natural resources, environmental pollution (for example, during the extraction of depleted hydrocarbon raw materials).

Industrial and entrepreneurship development, carried out without taking into account the impact on nature, can lead to serious problems both in the environmental condition, and, in the long term, on the economic development of society.

Not only individual citizens are responsible for making decisions to prevent environmental disasters and problems, but also the State. Public authorities need to develop and implement effective environmental management tools for economic purposes. Taxes occupy a special place here as a special form of control and regulation of the activities of business entities.

II. Methods

The main methods we used by throughout this work are

- methods of analysis and synthesis;

- a statistical method that made it possible to identify certain trends in the tax policy of the Russian state (based on the analysis of tax revenues and benefits);
- a comparative law method through which the main global trends in the development of taxes as an instrument for ensuring environmental safety were determined.

To conduct the study, we analyzed the data from the Federal Tax Service on the application of preferential taxation coefficients in connection with the use of highly effective environmental technologies.

As well regulatory documents of the Russian Federation and other countries aimed at regulating the environment through tax instruments were analyzed. Moreover, the research of theoretical economists and actual statistical data on environmental taxation in selected countries of Europe, Asia and America are considered.

III. Results

Today, environmental well-being is one of the main questions affecting the development of society in general and individual economies in particular. Special attention is paid to the issues of greening the use of natural resources in the process of their exploration for the development of industry and entrepreneurship.

The existing legal system of the Russian Federation, which provides for economic mechanisms to stimulate environmental protection activity through the introduction of tax and other liabilities for the use of natural resources, does not have the necessary tools for effective regulation and control over the implementation of environmental safety standards. This circumstance leads to a decrease in the level of pollution of the natural environment.

The experience of European countries in the field of the economy ecologization demonstrates the successful application of market instruments aimed at improving the state of the environment. There are environmental taxes and payments among them. Such financial responsibility is aimed at correcting the economic behavioral model of both producers and consumers, in the direction of reducing the negative impact on nature.

In addition, subsidies, tax incentives and preferences play an important role (for example, tax holidays for enterprises engaged in the protection and protection of fixed territories). Incentive measures are of great importance to stimulate innovative technologies and the introduction of new environmentally friendly technologies. Moreover, liability and compensation mechanisms occupy an important place in the environmental management system, providing compensation for environmental violations.

The existing in Russia payment system for negative environmental impacts does not fully contribute to solving the tasks of improving the environmental situation and preserving natural resources. This is related to the fact that the targeted use of funds for environmental needs is not guaranteed by either the tax administration or other government agencies. The problem of creating an effective system for monitoring compliance with environmental standards and norms remains relevant for many countries applying the environmental payment system. The reason for this is technical limitations in the sphere of monitoring and measuring the actual quantity of harmful emissions and discharges [3, pp. 453-457].

Unfortunately, Russian environmental taxation practice remains underdeveloped compared to foreign countries, where this system has become widespread and is actively used as a tool to encourage enterprises to choose environmentally friendly production technologies [7]. (Environmental taxation in this article refers to taxes in the field of environmental management).

The absence in Russia of a clearly defined legislative concept of "environmental tax" and an appropriate regulatory framework highlights gaps in the theory of taxation and limits opportunities for the formation of an effective environmental policy of the state.

The experience of the European Union countries since the 1970s has demonstrated significant achievements in the field of greening taxation. A centralized approach to the adoption of regulatory acts at the EU level, combined with the adaptation of the tax systems of individual states, contributed to the formation of an effective environmental taxation scheme.

The example of the United Kingdom is one of the most significant in terms of encouraging enterprises to carry out environmentally responsible production. In the UK, a tax on landfill with differentiated rates has been successfully operating since 1999. These rates depend on the type of waste. Moreover, in the UK there is a system of benefits for organizations investing in environmental projects.

Table 1: *Approaches to environmental taxation in different countries.*

Country	Types of environmental taxes and payments	Features	Application examples
In general	Electricity, coal, hydrocarbon derivatives, natural gas and gas condensate	Taxes do not promote emission reduction	
United Kingdom	Targeted environmental taxes	Tax revenues are used for environmental protection	
Germany	Noise tax, emissions taxes, waste and pollution payments, energy and transport taxes	Strict environmental policy policy; taxes based on environmental indicators of vehicles	Transport tax is calculated based on environmental indicators
Russia	Tax on engine power, fees for the use of natural resources	Non-ecological approach to transport tax; does not encourage emission reduction	Proposal to use the experience of Germany to encourage the transition to environmentally friendly cars
Finland	Carbon tax	Encourages the introduction of energy-saving technologies	Introduction of a carbon tax in 1990
China	Environmental Tax, solid waste	tax Tax benefits for companies that reduce emissions	Replacement of the pollution fee with an environmental tax in 2018
Brazil, India, South Africa	(There is no clear concept of "environmental taxes")	Start of development of environmental tax reform in Brazil	

[5, p. 304], [8], [9], [10], [11], [12].

This table provides examples of key aspects of environmental taxation of global economies, collected on the web pages of the legislative bases of various states. The purpose of the imposed taxes, their impact on the environmental safety of the country and the world are examined here, as well the preservation of the environment [5, pp. 302-306].

Special importance is attached to the development and implementation of a set of economic and market instruments aimed at minimizing the negative environmental consequences of economic activity.

The main directions in this area are:

- formation of a system of compulsory payments for the use of natural resources and emissions of pollutants, the amount of which should correspond to the costs of implementing environmental measures;
- transformation of approaches to the regulation of excess impacts on ecosystems through mechanisms of compensation for damage caused to the environment;

- introduction of tax benefits and preferences for "green" enterprises and organizations that carry out their activities without harm to the environment (for example, tax holidays or a reduced tax rate).

It should be emphasized that the subject of tax incentives are to be:

- technologies, including artificial intelligence, which more accurately determines the consequences of a decision related to the introduction of a particular tax; [2, p. 325]
- processes that meet the criteria of minimum waste, resource conservation and environmental cleanliness, which includes the use of the best available technologies approved at the legislative level;
- green energy and its use in production processes;
- human resources that develop non-toxic ways and methods of work (in production, logistics, sales of goods and services), etc.

It is important to support investments in the development of production facilities for the prevention, reduction and disposal of waste through recycling, along with the production of environmentally-friendly goods. Accordingly, the main recipients of tax benefits should be entities initiating scientific research and development in the field of ecology, as well as investing in the modernization and creation of new environmentally friendly manufactures [4, pp. 82-84].

The principles of resource recycling and waste-free production act as a fundamental base for the neo-industrial development of a modern economy. The implementation of an effective utilization and recycling system, in particular of motor vehicle waste, stimulates the intensification of research and innovation activity by both manufacturers and recyclers.

It is important to point out that the income from recycling fees should be used to finance infrastructure and environmental projects, including subsidizing the costs of enterprises for the implementation of waste management measures [5, pp. 302-306].

IV. Discussion

Effective ecological adaptation of business structures contributes to improving the quality of society life and stimulates economic progress. Therefore, improving the system of monitoring compliance with environmental laws is one of the most important aspects of public policy. Considering the tools of tax impact, it is important to mention that it enables indirect regulation of the multivariable activities of economic agents. That is why this study is aimed at analyzing and developing tax incentive mechanisms for enterprises to minimize their negative impact on the environment.

Research in the field of tax regulation of environmental policy reflects the relevance of the issues of development and implementation of tax instruments aimed at environmental optimization of economic activity. Many authors emphasize the advantages of environmental taxation in light of its ability to provide economic entities with flexibility in choosing strategies to reduce harmful effects on the environment [5, pp. 302-306].

The issues of tax support for technologies that are simultaneously characterized by a high degree of environmental friendliness, innovation and energy efficiency, as well as the problems of tax regulation in the context of waste management and decarbonization of the economy become the subject of detailed analysis in the works of many modern authors.

Since the current environmental situation has an increasing impact on human activities and, in particular, on economic activities, including production, logistics, and the sale of goods. It is important, in the context of the trend towards economic globalization (which has been shaken recently), to analyze world experience and bring effective tools to the international level. This means the introduction of mandatory environmental taxes and payments for all countries of the world, or at least for such communities as the CIS.

Focusing on the need to adapt the tax system to the current challenges of socio-economic transformations, it is important to consider various approaches to tax incentives for environmentally oriented changes in business practices and public relations, offering specific mechanisms for improving this system [6, pp. 59-61].

Initiatives aimed at introducing and developing the best available technologies, obtaining and using equipment capable of significantly reducing pollution levels. In addition, investments in the creation and modernization of facilities to reduce the volume and danger of waste should become the basis for tax incentives. These measures provide not only for improving the environmental situation, but also for stimulating research activities and the development of innovative technologies in the field of waste disposal and recycling.

The problem of the disbalance between income from environmentally oriented fees and environmental protection expenses requires comprehensive consideration and adjustment. At the moment, the established amounts of payments for pollution do not perform their main function - effective compensation the costs associated with eliminating environmental damage.

This highlights the imperfection of both environmental law and its administration system. In this regard, the need for a radical revision of approaches to tax incentives for environmentally responsible business behavior becomes obvious. This implies not only a reassessment of pollution payment standards, but also the introduction of measures aimed at strengthening responsibility for non-compliance with environmental standards, including a system of fines.

The existing payment system in the Russian Federation for negative environmental impacts shows clear signs of inefficiency and incomplete compliance with modern environmental and economic requirements. The immutability of the current strategy in the foreseeable future will inevitably lead to further degradation of the environmental situation.

And this, in turn, will provoke serious socio-economic consequences, including a decrease in production capacity and crisis in the economy. It is obvious that in order to prevent such negative scenarios, a comprehensive rethinking and qualitative updating of the environmental taxation system is required. It is also necessary to identify new areas for tax benefits and preferences that will facilitate the transition to more environmentally friendly and resource-saving production processes.

It seems advisable to introduce a set of tax exemptions for bonds belonging to the "green" categories and bonds focused on "national and adaptation projects" in the field of ecology. The key measures that can increase the attractiveness of such instruments for investors and at the same time help attract additional funds for environmental initiatives are:

- reduction of the corporate income tax rate to 10% in respect of income received in the form of interest on these bonds;
- reset the corporate income tax rate based on financial results arising from the sale or other disposal of these bonds, provided that the taxpayer has owned them for at least one year.

Such tax incentives not only contribute to expanding financial opportunities for the implementation of environmentally significant projects, but also activate the development of sustainable financing instruments. That fully corresponds to the strategic guidelines for the development of the financial market of the Russian Federation, outlined in the document "Main directions of budget, tax and customs tariff policy for 2024 and for the planning period 2025 and 2026 years" [13].

During the assessment of the fiscal consequences of the implementation of these measures, carried out on the basis of an analysis of data provided by the Moscow Exchange, it was revealed that potential shortfalls in the federal budget as a result of reducing the tax rate to 10% on interest income from "green" and "adaptation" bonds may amount to an insignificant percentage of the total tax income received from corporate income tax.

This highlights that the introduction of the proposed benefits will have a limited impact on the fiscal indicators of the budget, while the expected positive effect on the environmental sector of the economy and the promotion of sustainable investment may be significant.

The current law gives taxpayers the right to accelerate depreciation of the main technological equipment operated in the case of the use of the best available technologies with high energy efficiency or a high energy efficiency class (with a coefficient not higher than 2).Statistical data on the application of these benefits by taxpayers in 2020-2022 are presented in the Figure 1.

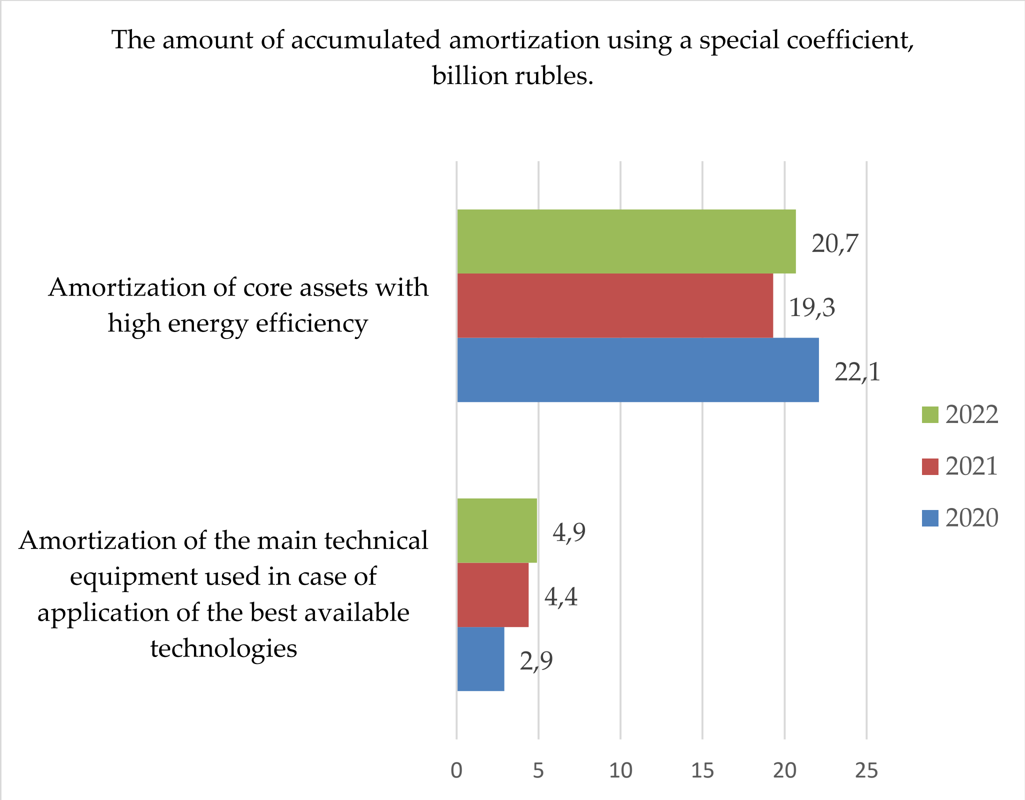

Figure 1: *The amount of accumulated amortization using a special coefficient, billion rubles.*

According to the presented data, it can be seen that the amortization of the main technical equipment used in the application of the best available technologies increased from 2.9 billion rubles in 2020 to 4.9 billion rubles in 2022. On the other hand, the amortization of core assets with high energy efficiency decreased from 22.1 billion rubles in 2020 to 20.7 billion rubles in 2022.

IV. Conclusion

Thus, analyzing the existing environmental situation and the tax system, it can be concluded that there is an imbalance between the amount of income from environmental taxes and the costs of protecting and restoring the natural environment. The established amounts of payments for environmental impact do not meet their original purpose — to compensate for the costs of eliminating negative consequences for the environment.

In this regard, it is necessary to realize that not all economic entities fully fulfill their obligations to pay environmental fees, which indicates shortcomings both in environmental legislation and in the system of its administration. The lack of targeted payments for environmental damage and the inadequate link between revenues and government expenditures on environmental protection measures indicate the inefficiency of the environmental payment system in force in the Russian Federation.

In order to overcome the revealed problems and to improve the efficiency of the existing tax system, it is necessary to carry out a comprehensive revamp:

- standards of tax payment for environmental impact on the environment;
- mechanisms for regulating and controlling taxation, including stricter responsibility (including criminal responsibility) for misdemeanors of environmental law.

Also, in our opinion, there is an inadequate tax burden on non-ecological enterprises. It is obvious that the Russian tax system is excessively lenient. We assume that in order to achieve the best results in the protection and protection of the environment, it makes sense:

- increase in tax rates for enterprises polluting the environment (industrial factories that neglect cleaning products, etc.);
- tax preferences for the introduction of innovative technologies, artificial intelligence into industry to reduce harm to the health of employees of enterprises;
- reduction of the tax rate for enterprises that take on responsibilities not only to minimize damage to nature, but also to restore the ecology of additionally appointed territories.

Thus, the ecologization of human activity should be systematic and considered by representatives of various scientific fields, including economists and lawyers. Only in close connection and with the introduction of a great number of economic and legislative restrictions and preferences – the safety of the environment is possible.

Abstract

Taking into account the main role of compressive stresses in the formation of local folds developed in the Ajinohur depression, the distribution characteristics along the depression, influence intensity and direction over the an idividual zones of the depression were determined.
For the analysis, the local folds of the Ajinohur depression were studied and they were scaled according to size on the plan. The isomorphic maping method was applied for the first time for qualitatively assess the intensity of compressive stresses in the study area. The influence direction of compressive stresses were determined.
The Ajinohur depression is located in the southwestern limb of the Greater Caucasus folding system close to the arch, terefore, the intensity of compressive stresses is higher. In the isomorphic map constructed for this depression, the isolines generally extend in the west-northwest-east-southeast direction, while isolines are relatively close in the longitudinal direction, at the same time, these are with high values (2.4-7.5 unit). So, it is indicate the high intensity of compressive stresses in the area. This situation is also confirmed by the morphological and isomorphic maps constructed on the same scale based on the dimensions of the local folds found here in the Neogene sedimentary complex. As can be seen from the maps, long brachyfolds are mainly more developed than the short brachyfolds in the area. The linear alignment of the folds in the all Caucasus direction and the complexation with upthrust faults indicate that compressive stresses play a major role in their formation.
The Ajinohur depression surrounded by the Kura-Gabirri, Yevlakh-Aghjabedi, Lower Kura, Shamakhi-Gobustan oil and gas regions. This regions are characterized by the presence of industrially significant oil and gas accumulations. İndustrially significance of these regions are identifide by the digging wells, and are characterized by the presence of numerous deposits that are in operation. It should be noted that there is a great risk of having industrially important hydrocarbon resources in the Acinohur possible oil and gas region, which is surrounded by promising oil and gas regions on four sides.

Keywords: Ajinohur depression, compressive stresses, upthrust, mud volcanoes, folds, oil, gas

I. İntroduction

Ajinohur depression, as is the object of the study, covers the northwestern part of the Kura intermountain depression and the southern slope of the Greater Caucasus folding system. İt is contains 28 local folds. Jurassic-Cretaceous and Pliocene-Quaternary sediments are spread in different parts of the area. Tectonically, the Acinohur area is divided into 3 zones. The folds that made up these zones are complicated by upthrust faults.

Ajinohur depression has a complex tectonic structure, geodynamically it is located adjacency of collision zones of Greater and Lesser Caucasus. İt is surrounded by the Ghabirri-Ajinohur basin from the west and stretches along the south of the Greater Caucasus megaanticlinorium. The folds located in the northern part of the depression complicated by cleavages and upthrusts with an enormous amplitude, are mainly Jurassic and Cretaceous age. The structures located in the area, which have a shingle- shaped, were formed by the influence of upthrusts. The sediments forming the section are terrigenous-carbonate. The uncovered thickness of Cretaceous system section is 3000 m [3,4].

The Pliocene-Quaternary age rock complexes are wide spread over the southern and central part of the depression.

A complete cross-section of the Productive series belonging to Lower Pliocene is exposed on the right bank of the Girdman River and is represented by two facies. The upper part of the section consists of grayish-brown clays and coarse-grained sands, and the lower part consists of alternating layers of different-grained sandstone and sand-clay interlayers. The thickness of the Productive series is up to 2000 m [5].

Aghjagil sediments are widely distributed within the Ajinohur. Lithological composition consists of hard limestone clays, sandstones and conglomerates. The thickness of these sediments is up to 1500 m.

Absheron sediments are spread over a wider area and lithologically consists alternation of coarse-grained sandstones and clays.

The Quaternary sediments are also widespread in the depression and it is section lithologically consists alternation of clays, sands and sandstones. Its thickness varies from 30 m to 1700 m [6].

5 anticlinal zones running parallel to the Greater Caucasus megaanticlinorium are singled out in the Ajinohur depression: 1. Dashyuz-Heyvanli; 2. Gudbarakdag-Gamigaya-Acibulag; 3. Acinohur-Savalan-Kurdmashi; 4. Khojashen-Goychay; 5. Bozdag-Garaja-Garamaryam [7,8].

In the mentioned anticlinal zones, local folds are mainly brachy and linear, and in rare cases, short brachy and isometric folds have developed. A characteristic feature of the folds is that they are complicated by upthrusts faults.

The amplitudes of the upthrust type of faults that complicate the folds located in the northwest of the area are greater than those of the same type of structures in the central and southern zones. The amplitude of the upthrust that complicates the Gudbarakdag structure located in the northwest of the depression is 1700 m, the amplitude of the longitudinal upthrust that complicates the Gamigaya fold located next to in the southeast is 700 m, while the amplitude of the upthrust that complicates the Western Khojashen fold is 1500 m [9,10]. This is due to the high intensity of compressive stresses in the northwestern part of the depression.

The southwestern limb of the Ajinohur depression dip steep. The reason for this the anticlines are asymmetric, echelon folding of the structures, and the complication of arch parts of the folds by upthrust type faults. The central and southern zone of the depression is characterized by this view.

Gradual weakening of intensity of disjunctive and plicative dislocations of different sizes distributed throughout the area from north to south is observed [11].

II. Method

The local folds developed in the Ajinohur depression are mapped to scale in the plan. In addition, the new method of isomorphic maps was applied for the first time in the research work, which allows qualitative assessment of the intensity of compressive stresses on the territory, as well as determining the direction of influence. As can be seen from the morphological scheme, the anticlinal zones formed by the local folds in the Ajinohur depression extend perpendicularly to the directions of compressive stresses, that is from the northwest to the southeast (Fig. 1).

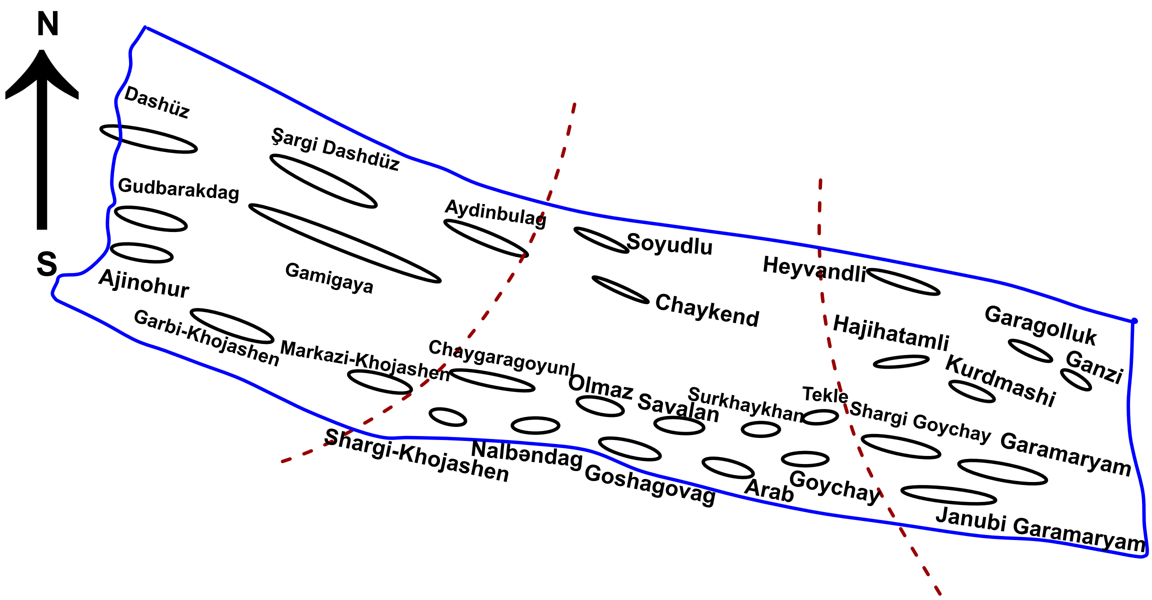

Figure 1: *Ajinohur possible oil and gas-bearing region. Morphological scheme of local folds*

-local folds, *-boundaries between of zones*

Ajinohur depression is characterised by the high intensity of compressive stresses. İt is confiemed by the course of the isolines from the west-northwest to the east-southeast on the isomorphic map drawn up for the area, the variation of the width-to-length ratio of the structures between 7.5-2.4 unit, as well as the contour intervals (Fig. 2). Based on the size of the folds, it is possible to distinguish 3 zones in the area: north-west, center, south-east. Short brachy and isometric folds are developed in the central part, while linear and long brachy folds are developed in the northwest and southeast part of the depression. According to the mentioned characteristics, local uplifts in all three zones have different morphology and are complicated by faults of different amplitudes. Folds were formed in zones of compressive stresses of different intensity. The difference in the structure of the folds is due to compressive stresses of different intensity.

Local folds in the Ajinohur depression, which rests on the West Caspian deep fault from the southeast, and is relatively close to the Greater Caucasus collision zone from the northeast, are long brachy and linear elongated forms, because they are more affected by compressive stresses. The folds located in the north-northwest part of the depression are more complex. Also, this structures are complicated by cover and upthrust type faults, with an amplitude of 1200-1300 m, while horizontal displacement is 2 km [1,12].

Despite the fact that the study area is located in a geodynamically active zone, the formation of long brachy and linear elongated folds, as well as comlpication of this folds by the cover and upthrust type faults due to the influence of high-intensity compressive stresses, mud volcanism did not develop in the area [13,14].

The relationship between mud volcanoes and compressive stresses can be determined by correlating some features of the geological structure. The sedimentary layer in the Ajinohur depression is relatively thin (7-9 km) and consists of 46% clayey, 48% sandy, and 6% carbonate sediments (Fig. 3).

Although the length-to-width ratio of local uplifts is 7.5 - 2.4 unit, several structures, for example, Garbi Khojashen, Shakgi Khojashen, Chaykend, Gamigaya were complicated by mud volcanism consisting of mud gryphons and salses related to the longitudinal upthrust type faults [15]. Mud gryphons and salses are accompanied by water flow with gas and oil films. Despite the high intensity of compressive stresses in the Ajinohur depression, the rheologically active clay mass that will create mud volcanoes in the cross section of the sedimentary layer has a low energy potential capable of forming mud gryphons and salses. There are a small number of salses and mud gryphons on the upthrust that complicates the folds along the axial line in the depression. İt is shows the transverse bending mechanism is involved for development of these folds. Despite of this, the linear arrangement of the salses and mud gryphons toward the all Caucasus direction, especially their genetic connections with upthrust type faults, shows that there is a main role of compressive stresses in the formation of there structures.

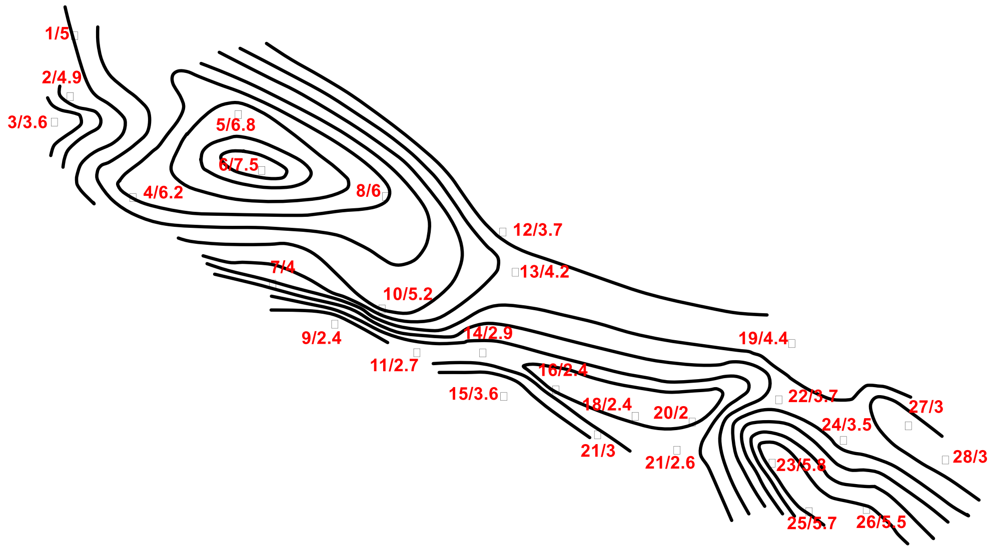

Figure 2: *Ajinohur possible oil and gas-bearing region. Isomorphic map*
1/5-well number (in the numerator) and the ratio of length to width (in the denominator);
-isohypses; - structures

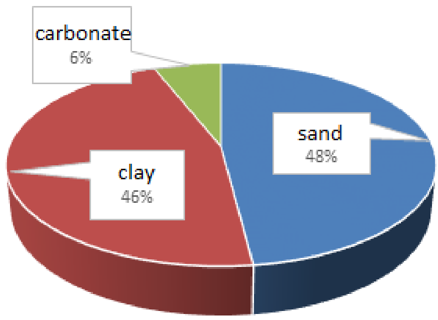

Figure 3: *Composition of the sedimentary layer in the Ajinohur depression*

It should be noted that the lithofacies composition of the sedimentary layer is one of the factors influencing the formation and types of both mud volcanism and faults.

If the rock complexes that make up the fold are relatively hard, that is, more competent, or if relatively plastic layers are in the minority in the section, then due to the tensile stresses created in the arch part of the fold, a relatively dense network of cracks is first formed, and then due to the continuation of the external influence in that zone, the integrity of the layers is destroyed, breaks, while as a result, the hanging wall of the fault under the effect of compressive stresses moves along the fault surface onto the foot wall and causes the formation of an upthrust type of fault [16].

As it can be seen from what has been said, upthrust (as well as shariage) type fault is actually the development of a plicative dislocation, that is a fold in the direction of a disjunctive, that is, a fault dislocation. In such cases, the reservoirs existing in the footwall, that is in the autochthonous (since they are screened by the allochthonous) can be promising in terms of oil and gas.

Thus, as can be seen from what has been said, the occurrence of residual (plastic or brittle) deformation in rocks as a result of external influence depends significantly on their physical properties, that is, whether they are competent or incompetent [8].

Due to the fact that the layers composed of competent rocks are more prone to brittle deformation, they undergo brittle deformation under the influence of compressive stresses and cause the formation of disjunctive dislocations in the development of folds.

As mentioned above, the northern tectonic zone of the Ajinohur depression is characterized by a wide spread of Jurassic-Cretaceous structures, where mainly competent terrigenous-carbonate sediments were formed. For this reason, the local folds developed here under the influence of compressive stresses are mainly complicated by upthrust, cover and sliding type faults. The fact that faults with huge amplitudes indicates the high intensity of the effected compressive stresses.

In the central and southern Ajinohur, the amplitudes of the faults that complicate the latitudinal directed anticlinal folds of the Pliocene-Quaternary sediments are smaller than in the northern zone. It is due to the lack of the intensity of the compressive stresses is relatively weak here, and at the same time, there are more incompetent rocks.

It is known that oil and gas are produced from almost all of the oil and gas-bearing regions surrounding the Ajinohur depression. Oil is exploited from wells dug into the Shirak formation and Sarmatian sediments in the Mirzaani-Aresh depression located in the north-west of Georgia [9,12]. Industrially important oil is extracted from Eocene sediments in the Tarsdallar area in the Kura-Gabirri interfluve oil and gas-bearing region, located in the western part, and the field is being exploited. Intensive oil flows were obtained from wells drilled in Mammadtepe, Demirtepe-Udobna areas. Oil and gas-bearing of Maykop sediments has also been proven here. Oil and gas manifestations from Sarmatian sediments in Sajdag, Armudlu, Chobandag, Palantoken, Akhtakhtatepe, Keyruk-Keylan areas were obtained. The oil-gas content of terrigenous-carbonate sediments of Eocene, Maykop and Chokrak in the Yevlakh-Aghjabedi, Ganja oil-and-gas-bearing region in the southwest has been proven. In the southeast, the Umbaki and East Hajiveli oil fields in South-West Gobustan are assossiated with the Chokrak horizon and sandy-siltstone reservoirs of the Maykop (Oligocene-lower Miocene) series.

Evidence of oil-gas content of Paleogene-Miocene, Pliocene sediments in the regions surrounding Ajinohur depression, analysis of geological-geophysical researches, structure-mapping drilling and exploration wells gives grounds for high assessment of the prospectivity risk of the mentioned sediments in this area.

III. Conclusıon

1. The intensity of compressive stresses in the Ajinohur depression is unevenly distributed along the area and section.

2. The north-western and south-eastern parts of the Ajinohur depression were more suffer to the influence of compressive stresses, while the central zone was relatively less.

3. The local folds of the Pliocene-Quaternary sedimentary complex in the Ajinohur depression were mainly formed as a result of the action of the longitudinal bending mechanism caused by compressive stresses.

4. Mud volcanism does not develop in the study area. The reason is assossiated with the sedimentary layer that is characterized by a relatively small thickness and the low clay content.

5. Oil-gas content of Paleogene-Miocene, Pliocene sediments in the regions surrounding the Ajinohur depression is identified, therefore, it is an indicator of the risk of formation of oil and gas accumulations in the reservoirs of the autochthonous limbs of cover-type structures in this area, taking into account other factors.

Abstract

The article discusses the features of the development of small and medium-sized businesses in conditions of sustainable development. Attention is focused on the concept of corporate social responsibility from the point of view of strengthening the socio-economic security of small and medium-sized businesses. The relationship between the imperatives of the concept of sustainable development and ensuring the security of the state of a small and medium-sized business, in particular in the socio-economic aspect, has been identified. It is substantiated that in the conditions of economic transformation and the transition to a model of a socially oriented market economy, it is necessary to harmonize the principles of managing the socio-economic security of small and medium-sized businesses with the targets of sustainable development, first of all, taking into account ensuring economic growth and achieving social progress.

Keywords: sustainable development, small and medium-sized businesses, social responsibility, enterprise personnel, government regulation, concept

I. Introduction

Achieving a high level of national competitiveness is impossible without ensuring the effective operation of small and medium-sized enterprises, stimulating the creation of a significant number of jobs [7].

In the conditions of the formation and development of a socially oriented market economy, the model of which is based on the requirement for an effective combination of market economic methods with state regulation of the national economy and its social orientation, the problem of sustainable development has become one of the main issues of today. The task of carrying out economic activities that do not deplete natural resources and are aimed at supporting the social sphere is becoming increasingly important for business.

Considerable attention from the world community is aimed at finding a balance between the economic and social needs of society while complying with environmental standards. Understanding the long-term problems of our planet and ensuring security are considered as a prerequisite for further sustainable and safe development for the functioning of both current and future generations.

The key need to solve problems of an economic, social and environmental nature, which are recognized as the triad of the concept of sustainable development, actualizes the problem of strengthening the socio-economic security of business entities in the context of transformation of the national economy.

The following scientists have studied the problems of sustainable development: A.B. Ankudinov [1], D.M. Borisov [1], V.I. Danilova-Danilyana [9], I.N. Gollai [2], M.E. Kadomtseva [4], N.A. Piskulova [9] and others. Recent scientific research in the field of socio-economic security indicates that in the modern theory of security in this area, a significant contribution is made by the works of leading scientists: N.L. Gryaznova [3], V.N. Druzhkova [3], E.V. Karanina [5], V.I. Lobanov [5] and others.

Despite the fact that socio-economic security is a fundamental category and the basis of the economy of the future, one of the effective factors in strengthening it in the context of transformation of the national economy and strengthening the social orientation of market reforms is taking into account the principles of the concept of sustainable and safe development in the further development. At the same time, further research requires questions of clarification of the essence of socio-economic security at the level of a business entity and its provision, taking into account the principles of the concept of sustainable development, which determined the choice of direction for this research.

II. Methods

The purpose of the article is to study the essence of the socio-economic security of an enterprise as a new category of economic security.

The importance of the SME sector is widely recognized throughout the world due to its significant contribution to various socio-economic goals such as higher employment growth, manufacturing, export promotion and entrepreneurship development [10].

In Russia in recent years, despite the not very favorable situation, the number of representatives of small and medium-sized businesses has been increasing. For sustainable existence and development, many of them need to integrate into the supply chains of large businesses and corporations and comply with the principles of sustainable development (ESG).

According to official data [6], at the end of 2023, 6.3 million small businesses were registered in Russia: 2.27 million – legal entities; 4.04 million are individual entrepreneurs. The number of small and medium-sized businesses is growing from year to year: by 7% in 2022, despite the "perfect storm" (negative effect of a combination of many unfavorable factors) of the external environment, and by 6% in 2023 [8].

Sustainable development of an enterprise is one of the basic values of its activities. Other important values - market position, profitability, scope of activity - without sustainable development in a turbulent business environment, as I. Ansoff wrote about in the 80s of the twentieth century, do not ensure the long-term activity of the enterprise. The history of entrepreneurship shows that long-term favorable conditions for the development of an enterprise are the exception rather than the rule. In practice, there is an alternation of favorable conditions and economic crises, including systemic global ones. The idea of alternating favorable and unfavorable conditions for the activities of an enterprise is not fundamentally new: the cyclical nature of business activity is covered in the scientific works of famous researchers.

III. Results

The development of an enterprise is important under any conditions of its activity, but it acquires particular value in times of crisis - as an effective way to overcome it, ensure the viability of the enterprise and the possibility of its further activity even in difficult unfavorable environmental conditions. During the periodic occurrence of crises in the external environment of the enterprise, a clear task arises - ensuring not only sustainable activity, but also the development of the enterprise in the decreasing part of the business cycle and at its lowest point - in the crisis. Moreover, we are not talking about an attempt to "wait out" the crisis, but about the active actions of the enterprise in unfavorable conditions, which should lay the foundations for its sustainable development in the ascending parts of the business cycle.

In accordance with the concept of sustainable development, which is recognized by the world community as the basis for the further sustainable existence of mankind, the most promising in the development of modern socio-economic systems is the idea of sustainable development based on the formation of the economy of the future to ensure the functioning of both present and future generations. The concept of sustainable development presupposes the unity of key components, which include economic growth, social progress and the environmental imperative [1; 2; 4]. Economic growth for the national economy presupposes the creation of a more competitive and highly efficient economy, which has a positive effect on increasing the standard of living of the population and improving its well-being. Only in conditions of ensuring the full use of all benefits provided in the social sphere, economic growth contributes to sustainable development, that is, the economic priorities of sustainable development include compliance with the principles of equality and social justice.

The problem of sustainability of socio-economic systems in the context of sustainable development is manifested in all its dimensions: economic, social and environmental. Strengthening the social orientation of market reforms makes it necessary for the state's socio-economic policy to be aimed at achieving high standards of quality of life and universal human values. Economic security depends on the state of the labor market, the level and dynamics of wages, the effectiveness of social and other components of state policy. In the socio-economic aspect, sustainability involves solving issues of poverty, employment, leveling the stratification of society by property status, ensuring access to education, protecting the health of citizens, preventing a decline in the birth rate, increasing life expectancy, eliminating deformation of the demographic and social structure of society and social conflicts and etc. It should be noted that among the goals of sustainable and safe development, according to the concept of sustainable development, along with the priority of economic growth, there is the need to comply with the principle of social justice, stabilize the population and increase its level of well-being, access to education.

Dynamic changes in the development of society at the present stage are accompanied by a certain aggravation of socio-economic and resource-ecological problems, the basis for solving which is the transition to a model of sustainable development, as M.E. quite rightly emphasized. Kadomtsev [4]. The concept of "sustainable development" in the modern sense and the basic idea of safe development have become widespread since the late 80s of the twentieth century. From the point of view of interpreting the concept of sustainable development as a dominant idea for the further development of human civilization, the unity of the economic, social and environmental components, which reveals the essence of the concept itself, also reflects a certain level of economic security. Therefore, a scientific approach to studying the state of ensuring economic security and its most important components, taking into account indicators of sustainable development, is common.

The concept of sustainable development in the context of the concept of the further balanced existence of society is comprehensive and multifaceted, since it concerns the implementation of this principle at all levels of the economic system - both at the global, national and regional, and at the microeconomic level. This means that the global task of ensuring the sustainability of socio-economic systems at the current stage of development and in the long term must be implemented through specific tasks at each of the hierarchical levels of the economic system. In a market economy, the problems of sustainable development of enterprises as the basic level of the economic system become of particular importance. Taking this into account, it is appropriate to focus on the results of a study of the sustainable development of an enterprise as a necessary condition for the successful functioning of a business and its relationship with the sustainable development of socio-economic systems of the highest level, given by the author in [2]. In another work, the authors [1] point out the need to intensify the social responsibility of all subjects of ensuring social security, subject to the failure of the state to respond individually and in a timely manner to the aggravation of existing threats associated with accumulated social problems and the increasing level of social tension. At the same time, corporate social responsibility of a business is considered as a factor that has an impact on ensuring social security. The social responsibility of an enterprise in a market environment is implemented through such areas as: social responsibility to employees (working conditions, decent wages, motivation and reward system); social responsibility of the enterprise to the state (timely payment of taxes and other payments); social responsibility to the society of the territories in which the enterprise operates (expenses to improve the living conditions of the population, programs for participation in public life). According to the authors [1], social responsibility is an integral part of socio-economic security, and at the same time it is a factor influencing its level. Social security of business is a guarantor of social security of the population.

As part of the study of the content of the category of socio-economic security and its objects, the work [5] states the fact that the constant development of economic security has led to the identification of new types of economic security, therefore, along with the already established categories of economic security and social security, the category "socio-economic security", which should not be considered as the result of a merger of social and economic security. Socio-economic security is formed in the process of interaction between economic and social security, while the social component acts rather as a superstructure of the category of socio-economic security, since the growth of activity and productivity of economic entities is not the final goal, such growth should affect the well-being of the population, in particular thanks to increasing wages, the volume of social assistance, improving the quality of social services.

The strengthening of mutual coherence between the social and economic components of development is due to a number of trends, since economic security as a complex characteristic of the development of an economic system synthesizes all forms of manifestations of social relationships that can cause a real or potential conflict of interests.

Naturally, the concept of security requires a new dimension in the status of socio-economic. When analyzing the definitions of socio-economic security of an enterprise in their work, the authors [9] point in this context to the ability of an enterprise to withstand adverse external and internal influences by harmonizing socio-economic interests in order to ensure sustainable activities, that is, the concepts of "sustainable development" and "social -economic security of the enterprise" are closely interconnected. The implementation of the economic interests of a business entity (primarily making a profit) and conducting a socially responsible business (social responsibility to employees, the state and society) influence to a certain extent the level of socio-economic security of the enterprise and create the basis for ensuring the security of the state of such a business entity. Proponents of the harmonization approach to the interpretation of the essence of the socio-economic security of an enterprise consider the conditions for ensuring the socio-economic security of an enterprise through the prism of multi-vector harmonization of the interests of the enterprise with the subjects of the external environment. At the same time, the social significance of the activities of large industrial enterprises can be traced during the provision of jobs and income to residents of the territories, replenishment of local budgets, construction and maintenance of social infrastructure.

Among other factors in increasing the level of economic security of an enterprise, a significant role is given to managing the motivation of the enterprise's personnel as one of the conditions for the safe development of a business entity. The level of satisfaction of the socio-economic needs of workers in relation to the development goal affects the feeling of security and safety. If a sufficient level of material remuneration for the corresponding work forms the basis for satisfying the economic needs of the employee, then the main factors for realizing the social interests of the staff should be noted the needs for self-expression, recognition of individual successes, social relations of the employee, creation of prerequisites for his self-development, etc. In terms of increasing social - economic security of a business entity, it should be noted the formation of an effective system of personnel motivation, which makes it possible to fully satisfy both economic and social needs in the process of work.

IV. Discussion

In the process of clarifying the essence of the concept of socio-economic security of an enterprise, V.N. Druzhkova, N.L. Gryaznova [3] come to the fair conclusion that social and economic security are decisive in the activities of an enterprise, based on the fact that the main value of an enterprise is its personnel, and the level of labor productivity, opportunities reproduction and efficient use of labor resources. At the same time, studies of the social aspects of sustainable development suggest that the sustainable development of an enterprise is due to a certain mutual consistency of socio-economic interests, since in order for an enterprise to pursue an effective social policy, it is necessary to achieve a sufficient level of economic security.

Differences in approaches to defining the essence of social responsibility of business are explained by the predetermination of the content of this concept by local economic traditions, the scope and specifics of doing business, the size of the enterprise, the geographic region in which it operates, and, of course, the time horizon. Among the features of the considered definitions of social responsibility of business, it is necessary to highlight the voluntary nature of such activities and the orientation towards achieving business success, which does not contradict socially responsible goals.

Summarizing the views of researchers, it should be noted that the system of social responsibility of business is a complex set of relationships between business and stakeholders, which is focused on obtaining social, economic and environmental benefits in the process of economic activity, which will not harm society and the environment. It is the balancing of the economic, social and environmental interests of humanity that must be ensured through a responsible attitude and mutual understanding between individuals, the state, society and business structures. This will ensure the formation of a favorable environment for the beginning of new thinking and the correct perception of one's significance and purpose in society.

Consequently, it becomes important to ensure that businesses have a responsible attitude towards the environment, the process of producing safe products, providing their employees with the necessary benefits, meeting the needs of consumers, as well as interaction with various groups of stakeholders. This approach is due to the combination of environmental, economic and social components of sustainable development, thanks to which it is possible to achieve the introduction and implementation of modern strategic guidelines for social responsibility of business.

For most modern enterprises, the basis is compliance with ethical standards in operations and regular and fair remuneration of employees. But more and more companies are becoming convinced of the need to improve management systems in order to develop mutually beneficial relationships with all stakeholders in order to realize all the benefits of a corporate responsibility strategy: creating increased investor interest in the company; increasing customer and stakeholder loyalty; increased social awareness of consumers; improving relations with society and local authorities; increasing competitiveness; increasing the level of organizational culture; formation of a positive image of the enterprise among employees; attracting and retaining the best employees, etc.

An enterprise is not only an economic unit and an instrument for generating profit, it is also a system that influences and is itself influenced by its environment: suppliers, consumers, local communities, public organizations, as well as employees, shareholders and investors. The CSR strategy should become a standard element of the company's development strategy, and activities within its framework, the desire to gain competitive advantages with a simultaneous sense of civic duty, will become the main motive of business entities implementing this idea.

It should be especially emphasized that the socio-economic security of an enterprise guarantees sustainability and stability, that is, it is closely related to the conditions for ensuring the sustainable development of the enterprise. This allows us to point out the dialectical relationship between the sustainable and safe development of a business entity and the socio-economic security of an enterprise, which are inextricably linked. Indeed, speaking in the terminology of the concept of sustainable development, it is economic growth that forms the potential, which, in turn, creates the basis for meeting the socio-economic needs of workers, protecting their interests and rights and improving the quality of life, that is, in general, contributes to the achievement of social progress , which ultimately affects the ability to ensure an appropriate level of socio-economic security of a business entity.

At the present stage of transformation of the national economy and its transition to a model of a socially oriented market economy, problems of sustainable development must be solved in combination with issues of ensuring an acceptable level of socio-economic security of domestic enterprises, which is fully consistent with the postulates of the concept of sustainable and safe development of society.

Consequently, in conditions of increasing social orientation of market transformations, the balanced development of an individual enterprise in the light of the concept of sustainable development provides for the unity of its components and reflects the level of socio-economic security of a business entity, which creates grounds for subordinating the principles of managing the socio-economic security of an enterprise to the fundamental goals of its sustainable development.

Abstract

The article examines the essence of tax risks, based on the international experience of various countries. Undoubtedly, the topic of our research is quite relevant at the present stage of the development of economic relations. After all, as we see it, the role of taxes is very significant for any state, since taxes act as the main source of state budget replenishment of practically any country. But at the same time, there are many dishonest taxpayers who try to avoid tax payments as much as possible, using various tools to optimize the burden of taxation, including illegal ones. In addition, during the research we identified the main zones of tax risk for identifying dishonest taxpayers in various foreign countries.

Keywords: taxes, tax risks, economics, burden of taxation, tax optimization, tax legislation, tax control

I. Introduction

Under the conditions of modern developing economic relations, such a phenomenon as “tax risks” is acquiring universal significance in the field of taxation. This phenomenon is influenced by many processes and factors that occur all over the world. Unfortunately, the analysis of the financial and economic situation for most countries shows a process of reduction in tax revenues to the country's budget, which, in turn, is accompanied by a decrease in the revenues of the state budget of a particular country. In this connection, the relevance of the topic of our research, devoted to the study of the essence and nature of tax risks, the reasons for their occurrence, as well as the search for methods to fight them, increases.

Note that the term “risk” takes its impetuous origin from the very development of market relations. As for tax risks, they should be classified as a group of economic risks, which, in turn, include other risks, such as financial, banking, insurance, etc. In addition, many economists classified tax risks as financial risks before. But, subsequently, economists came to a common opinion about classifying them as an independently existing type of economic risks. As practice shows, currently there is no clearly formed concept of tax risks, both from the practical and theoretical sides.

But despite this fact, many researchers classify tax risks into two main groups:
- ✓ Risks on the taxpayer`s part;
- ✓ Risks on the state`s part.

That is, simply put, the risks on the state`s part consist in the shortfalls of tax revenues from citizens to the state budget due to various tax minimization schemes.

But for citizens, tax risks are associated with the imperfection of the country's tax legislation, increase of burden of taxation, etc.

Thus, summarizing all the above, we can come to the following definition of the essence of tax risks, which is interpreted as the probable occurrence of negative material, primarily financial, consequences either for the state or for the taxpayer in connection with the actions or inactions of certain participants of tax legal relations. In other words, for both the taxpayer and the state, the concerned category serves as a source of financial losses. As it is known, there are internal and external factors that influence tax risks for both taxpayers and the state. As for the internal factors of tax risks for the state, we would like to note, first of all, the tax policy pursued in the country. As for taxpayers, it is the procedure for submitting tax reporting and paying taxes, as well as tax planning. External factors of tax risks for taxpayers cover such phenomena as changes in terms of taxation. As for the state it is the creation and existence of offshore zones. Let's also add a common external factor for both the state and taxpayers, which is the world price situation for exported products and the general state of the world market.

Thus, summarizing all the above, we can conclude that tax risks in any case are accompanied by negative consequences that have a financial nature and consist in losses, damages, as well as shortfalls in profits and income.

In addition, tax risks are associated with the probability of negative consequences of a legal, social and psychological nature.

That is why the importance and relevance of studying tax risks, the reasons for their occurrence and ways to minimize them is increasing every day.

II. Methods

The fundamental goal of our research is to identify the essence of tax risks and the main methods to fight them, based on international experience.

The subject of our research is to find ways to reduce tax risks. And the object is tax risks.

In the course of writing this scientific work, various textbooks, teaching aids, works of both domestic and foreign scientists and economists, as well as periodical articles, magazines and Internet resources devoted to the topic of our research were used.

III. Results

Thus, having studied the phenomenon of our research, we`d like to consider the main reasons for the emergence of tax risks.

First of all, we would like to note the imperfection of tax legislation as the first reason for the tax risks formation. In our opinion, this factor can have a negative impact on both taxpayers and the activities of the state. Drawing on the modern experience of many countries around the world, one can observe the manifestation of imperfections in tax legislation in matters of taxpayers reducing their tax obligations, which, in turn, automatically reduces state revenues through reduced tax revenues.

On the other hand, the actions of taxpayers can have very legal grounds with due to additional assessments by the tax authorities, which, in turn, is accompanied by financial losses and various legal proceedings. As the next reason for tax risks, we`d also like to note the ambiguity and inaccuracy of judicial practice regarding tax administration. After all, a situation where courts make very ambiguous decisions on the same issue it often observed.

In the emergence of tax risks, a key role is also occupied by the incompetence of personnel, as well as various technical errors, or intentional ones, which are often accompanied by deliberate noncompliance with the law.

Moreover, as we see it, such a phenomenon can occur both on the part of the state and taxpayers. To minimize tax risks, countries are actively pursuing tax policy, which is aimed at improving the quality of audits, applying the basic principles of taxation that are applied everywhere in many foreign countries, as well as bringing closer together in matters of information interaction between various authorities, in particular customs, law enforcement, tax authorities, etc. That is, the state’s main aim is to fight against dishonest taxpayers who use one or another method to hide the taxation base. As for tax risks, we`d also like to focus on those large taxpayers who register in offshore zones.

This, in turn, negatively affects the financial component of any country, since it can result in a decrease in the amount of revenues to the country’s budget.

Thus, we`d like to summarize all of the above and note the main well-known causes of tax risks:

✓ Introducing various amendments and changes to the country’s legislation, in particular, the abolition of tax benefits, or an increase in the tax rate, which is risky for taxpayers with not updating their tax accounting;

✓ The emergence of contradictions in regulatory documents in connection with various amendments;

✓ Lack of qualified personnel who can correctly calculate the taxation base, amounts of taxes and contributions;

✓ Unscrupulous analysis on the part of companies when concluding transactions with unreliable counterparties;

✓ Use of illegal schemes by taxpayers to optimize the burden of taxation.

IV. Discussions

Besides, during the research, we identified and classified the main groups of tax risks, based on the international experience of foreign countries.

For clarity, we would like to refer to Table 1 below.

Thus, based on the data presented, we clearly see that most countries note the use of taxpayers of various schemes involving offshore companies as the main source of tax risk.

Also, an important place is given to the factors of abuse of double tax agreements, the formation of artificial losses and the application of imperfections in tax legislation.

Table 1: *The main area of tax risks according to the international practice of foreign countries*

Country	Main areas of tax risks
Australia	✓ Tax schemes aimed at tax evasion using prepaid options for services; ✓ Use of new financial instruments; ✓ Schemes aimed at removing company assets (variation of the wage fund, use of offshore companies, “thin capitalization” tools).
United Kingdom	✓ Artificial creation of losses: using offshore bank accounts to hide assets and income.
Germany	✓ Transfer of income to low-tax jurisdictions; ✓ Abuse of double tax agreements; ✓ Tax evasion by permanent representative offices of foreign organizations.
Ireland	✓ Schemes using offshore companies; ✓ Concealment of income and capital gains; ✓ Artificial creation or “inflation” of losses; ✓ Abuse of double tax agreements.
Spain	✓ Real estate schemes;

	✓ Use of offshore companies; ✓ Tax planning.
Italy	✓ Schemes using offshore companies and trusts; ✓ Comprehensive contractual schemes both at the national and international levels; ✓ Abuse of double tax agreements.
Canada	✓ Transactions aimed at artificially understating income and asset value growth, inflating expenses, overstating losses; ✓ Abuse of double tax agreements; ✓ Illegal use of tax benefits; ✓ Use of offshore companies, transfer pricing; ✓ Intentional bankruptcy.
South Korea	✓ Schemes using "trading agreements"; ✓ Tax evasion using offshore companies; ✓ Use of derivative securities in schemes to create artificial losses and tax deferral.
Netherlands	✓ Schemes aimed at distorting the taxation base; ✓ Offshore companies; ✓ Individuals with a high level of income and a significant value of their property.
New Zealand	✓ Income split and creation of artificial losses (for individuals); ✓ Exploitation of "gaps" in tax legislation, often using financial instruments (for companies).
Norway	✓ Schemes using offshore companies
USA	✓ Schemes using imperfections in tax legislation; ✓ Tax evasion using offshore structures to hide income, creating artificial expenses and losses.
France	✓ Tax offenses on a particularly large scale, especially at the international level; ✓ Non-declaration of economic activity.
Sweden	✓ Schemes using offshore companies, bank cards and foreign holding companies (for individuals, small and medium-sized businesses); ✓ Schemes with commercial real estate, loans (of a company).
Japan	✓ International tax planning schemes based on preferential provisions of foreign tax systems and abuse of double tax agreements; ✓ Use of foreign shell companies; ✓ Use of new financial instruments in schemes.

Thus, we can conclude that the tax risk assessment system acts as a many-sided element and can be considered in various aspects depending on the organizational and operational structure of tax authorities.

In other words, some countries focus on referring risks to certain groups of taxpayers, in particular such groups as:

- ✓ Individuals;
- ✓ Small and medium-sized business;
- ✓ Large corporations;
- ✓ Individuals with large incomes and property.

Other countries are studying the risks from the point of view of the legality of using basic tax planning tools.

It concerns, for example, the use of double tax agreements, which serves as a formal method of tax optimization, but at the same time has high tax risks for the budget.

But the situation of non-declaration of income and property undoubtedly serves as an illegal way to optimize taxes.

In our opinion, the proposed and discussed above methodology of systematization and segmentation of tax risks, which acts as the basis of tax monitoring, serves as the most important factor in building an effective system of tax administration.

V. Conclusion

Thus, based on the foreign experience of various countries in identifying tax risks, we can draw a conclusion about the important role of introducing penalties at the legislative level for promoters (lawyers, auditors, etc.) of aggressive tax planning schemes (promoter penalty regime).

Such obligations exist in the laws of other countries, in particular in Canada, New Zealand, Australia, the USA, and the UK.

Thus, based on the experience of developed countries, we can conclude that their tax services carry out their work using a comprehensive analysis of tax risks.

In our opinion, the development of a tax monitoring system, which is based on risk management techniques, will become an auxiliary tool in identifying certain problems of tax administration and legislation at the early stages of their manifestation.

In addition, we support the idea, the essence of which is that if there are certain measures to identify information, as well as appropriate structural units for tax monitoring, the success of the state tax policy implementation will be manifested through the timely detection of certain tax risks and their effective management.

Thus, we revealed the topic of our research.

ESG APPROACHES IN BUSINESS AS THE FORMATION OF NEW THINKING

Ekaterina Nezhnikova
•
RUDN University, RUSSIA
nezhnikova-ev@rudn.ru

Abstract

ESG approaches are based on the philosophy of sustainable development of economic activity, which follows the principles of a responsible attitude to the environment, high social responsibility, and high quality corporate governance. In Russia, the principles of ESG are less common than abroad, but they are already gradually being introduced into business. At the same time, the three categories of ESG are increasingly being integrated into investment analysis, processes and decision making. Many Russian companies are firmly integrated into the agenda by implementing numerous projects, as developed countries are pushing domestic companies to implement such standards to improve the image and investment attractiveness of companies. And here we should not forget about the importance of both climate change issues and corporate governance practices, as well as the efforts and achievements of companies in the field of ecology and social responsibility, which, on the one hand, is the matter of being responsible for the well-being of employees, and, on the other hand, is contribution into the development of the territories where such companies are located.

Keywords: environmental, social, corporate governance, competitiveness of the economy, sustainable development

I. Introduction

An increasing number of investors, especially in the West, when making decisions about investing in a particular company, take into account its impact on the environment and society. The United States is expected to introduce mandatory requirements for issuers to disclose financial information on climate risks and greenhouse gas emissions, and is also expected to introduce, following the example of some European countries, mandatory standardized disclosure of ESG information.

Russian business is also increasingly interested in the principles of responsible investment. ESG stands for Environmental, Social, and Corporate Governance. In 2022, President of the Russian Federation Vladimir Putin instructed the Government of the Russian Federation to consider determining the criteria for classifying investment projects as projects that meet the requirements of the concept of environmental, social and corporate responsibility (ESG).

A significant increase in interest in this agenda is directly related to such factors as environmental problems, a sharp aggravation of social and economic inequality. The global competitiveness of the country's economy and the ability to achieve sustainable development goals will largely depend on professionals in the development, evaluation and management of ESG projects.

II. Methods

The theoretical and methodological basis of the study was the theory of sustainable development, supply and demand in the manufacturing sectors of the economy, quality management, institutional design, research on the competitiveness of firms and goods; environmental friendliness; economic laws of modern market economy; concepts, strategies, various developments and scientific hypotheses of Russian and foreign scientists and experts in the field of economics and industry management. In the process of research, the author used general scientific methods of systemic and comparative analysis, expert assessments, modeling of multifactorial dependencies of complex systems, sociological research, analysis of hierarchies, economic synergy, rating assessment; methods of statistical and mathematical analysis; the principles of logic, purpose, functionality.

III. Results

The abbreviation ESG can be deciphered as "environment, social policy and corporate governance" (Fig. 1). In a broad sense, this is the sustainable development of commercial activities, which is based on the following principles:

1. environmental responsibility (E — environment);
2. high social responsibility (S — social);
3. high quality corporate governance (G — governance).

In Russia, the principles of ESG are less common than abroad, but they are already gradually being introduced into business. One of the topical issues is the reduction of carbon dioxide emissions from the extraction and processing of fuel, as well as the development of new energy sources. As part of the national project called 'Ecology', the task was set to send 100% of waste for sorting by 2030 and to halve the volume of waste disposal. In addition, a third of the country's largest banks have already introduced ESG-assessment of companies into the lending process, and another 20% are planning to. This means that banks will test each borrower for compliance with the principles of sustainable development.

Climate dominates discussions on the ESG agenda, but there is no single list of goals, and concepts often overlap. At the same time, the three categories of ESG are increasingly integrated into investment analysis, processes and decision making (Fig. 1).

The demand for ESG standards in Russia, despite the difficult relations with the West, will continue, and these standards will be adjusted depending on their compliance with real tasks and priorities. Many companies are firmly integrated into the agenda, having implemented numerous projects, as developed countries are pushing domestic companies to implement such standards to improve the image and investment attractiveness of companies. And here it is important not to forget about the responsibility for the well-being of employees and the contribution to the development of the territories in which they work.

Many companies in Russia understand the need for sustainable development in the long term and provide competitive advantages, such as lower lending rates, protection from competition, and gradually become a formalized communication channel: government-business, community-business, society-business, etc.

At present, Russia has formed its own rating of sustainable development of Russian companies. The rating consists of four components:

1. ***Social policy and personnel:***

- staff turnover
- involvement of personnel in the learning process (improving the professional level of employees)
- formation of a personnel reserve of university graduates and trainees
- voluntary medical insurance programs
- health-improving treatment of employees
- indexation of wages to a level not lower than inflation
- investment in work safety

- no injuries at work

2. *Ecology:*

- environmental costs
- implementation of the processing of all waste
- implementation of secondary processing of raw materials
- voluntary programs in the field of ecology that are not related to direct production activities

3. Development of the region of presence:

- programs for the formation of a comfortable urban environment
- the number of regions of the Russian Federation where social programs are being implemented
- donations to charity
- availability of programs and investments that are in line with the SDGs (sustainable development goals) - 2030.

ENVIRONMENT	***SOCIAL***	***GOVERNANCE***
carbon footprint, greenhouse gas emissions, biodiversity, energy efficiency, climate change and pollution reduction, waste management, water use and deforestation.	labor standards, wages and benefits, racial justice, pay equity, human rights, talent management, public relations, privacy and data protection, health and safety, supply chain management and other issues of human capital and social justice.	includes "E" and "S" category governance – corporate board composition and structure, oversight of strategic sustainability and compliance, executive compensation, political input and lobbying, bribery andcorruption.

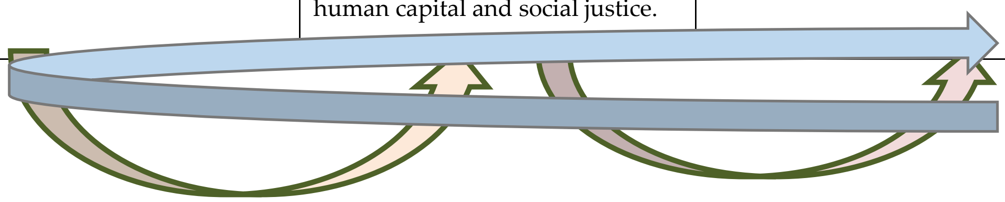

Figure 1: *Philosophy of ESG approaches*

4. Working with small and medium-sized businesses - the share of purchases from small and medium-sized businesses in the total cost.

The most important indicator of the development of an innovative economy is human capital, the country index (human capital index) of which depends mainly on the level of education and health of the economically active population. The level of this indicator directly affects the productivity of people involved in the development of an innovative economy.

According to the latest data from the World Bank, Russia is among the countries with an average level of the index at 0.68 (a high value starts at 0.7). And although the level of education of specialists in the Russian Federation is higher than in some countries with high HAI values, Russia is still inferior to them in terms of the health of specialists. That is why corporate healthcare initiatives now play a special role.

The most important area for investment in human capital is the development of professional educational programs and support for educational institutions in the preparation of future highly qualified specialists.

ESG standards are not only the quality of education and healthcare, but also the development of the urban environment with which local residents interact every day. Therefore, favorable conditions must be created everywhere in order for highly qualified specialists not to seek to change their place of residence for the sake of a more comfortable urban infrastructure. In Russia, the national project "Housing and Urban Environment" is devoted to achieving this goal. The key goals of the national project are to provide affordable housing for middle-income families, including creating opportunities for them to purchase (construct) housing using a mortgage loan, increase the volume of housing construction, improve the comfort of the urban environment, create a mechanism for direct participation of citizens in the formation of a comfortable urban environment, ensuring a sustainable reduction of the uninhabitable housing stock.

Successful cases of the largest Russian companies implementing ESG principles and projects in their practice are presented below (Fig. 2,3,4).

LUKOIL GAZPROM NOVATEK ROSNEFT	SUPPORT REGIONS	1. Landscaping 2. Creation of a comfortable urban environment in small towns and historical towns (play areas for children, organization of winter games), an environment suitable for comfortable life (this solves the staff turnover problem) 3. Support for healthcare, purchase of equipment, opening of medical laboratories 4. Development of tourism 5. Support for the culture of indigenous peoples 6. Repair and construction of sports facilities 7. Support for children's sports 8. The volume of funds for charity is growing 9. Construction and restoration of churches
ELSIE (Coal Company) SUEK SIBUR EUROCHEM	ECONOMIC DEVELOPMENT OF REGIONS	1. Attracting investments to the region by creating its attractive image 2. Increasing economic and tourism potential 3. Implementation of tourism projects (Murmansk region), due to this, stimulation of the development of small and medium-sized businesses, transport, hotels, trade, catering 4. Volgograd region - projects to increase the cultural and tourist attractiveness of the region (the birthplace of Stepan Razin, the site of the Battle of Stalingrad) 5. Support for city initiatives and participation in various federal targeted programs 6. Support for initiatives coming from people (urban development projects, cultural projects, volunteer and environmental initiatives)

Figure 2: *ESG projects in terms of support and development of the regional economy*

EUROCHEM Phosagro MMK (Magnitogorsk Iron and Steel Works) SUEK OMK (United Metallurgical Company) →	SOCIAL POLITICS →	1. Human resources management with good care (management with a human face) 2. Comfort and quality of workplaces 3. Wage increase 4. Development of methods of long-term motivation 5. Funding for charitable projects 6. Corporate housing programs 7. Rehabilitation of employees' children 8. Support for local educational institutions in preparing for future industry specialists, organization of career guidance tours 9. Creation of educational and industrial clusters (integration of education with production) 10. Creating conditions for the development of schoolchildren's talents and support for talented students 11. Rehabilitation programs for veterans (coal industry) 12. Implementation of active longevity practices

Figure 3: *ESG projects in terms of social policy development*

NLMK (Novolipetsk Iron and Steel Works) PHOSAGRO OMK TMK →	ECOLOGY →	1. Production of ecological fertilizers (from ore of volcanic origin, unique in its purity) 2. Creation of carbon polygons and farms designed for monitoring greenhouse gases (planting trees near industries) 3. Protection of water resources (installation of the most modern industrial wastewater treatment systems, an innovative system for storm and wastewater treatment) 4. Emission reduction programs and recycling 5. Introduction of water-saving technologies, regulation of water demand 6. Closed cycle of use of water resources within the framework of production processes 7. Conservation of biodiversity (TMK released 28.5 thousand sturgeon fry into the Sea of Azov basin) 8. Involvement of employees and volunteers in the cleanup of territories and settlements 9. Reforestation. landscaping 10. Environmental education projects 11. Solving problems of soil pollution 12. Selection of partners with an ecological approach to production and high social responsibility

Figure 4: *ESG projects in terms of supporting regions*

To calculate the synergistic socio-ecological and economic effect from the implementation of ESG projects, it is proposed to understand the ratio of the effectiveness of these projects and the costs associated with them.

Due to the significant amount of information and the complexity of calculations, it is proposed to use an indicative method to determine the synergistic socio-ecological and economic efficiency of the implementation of ESG projects.

1. The complex economic index of social, environmental and economic efficiency of the implementation of ESG projects is proposed to be calculated according to formula 1:

$I_{\text{эк}} = k_1 i_{in} + k_2 i_{comp} + k_3 i_{br} + k_4 i_H + k_5 i_{in},$

k_1, k_2, k_3, k_4, k_5 – specific weights of the contribution of each chain index to the economic complex index of socio-environmental and economic efficiency of the implementation of ESG projects; $k_1 + k_2 + k_3 + k_4 + k_5 = 1$;

i_{in} – index of increase in investments in the economy of the region per year;

i_{comp} – index of competitiveness of enterprises in the region;

i_{br} – index of complex competitiveness of industries in the region;

i_H – index of the proportion of families that have the opportunity to purchase housing using their own and borrowed funds;

i_{in} – growth index of potential income received by employees from the increase in their labor productivity due to the improvement of their working conditions.

2. The complex social index of socio-environmental and economic efficiency of the implementation of ESG projects is calculated according to formula 2:

$I_{\text{соц}} = m_1 i_H + m_2 i_{NF} + m_3 i_{\text{р}} + m_4 i_{\Delta C}$,

m_1, m_2, m_3, m_4 – specific weights of the contribution of each chain index to the social complex index of socio-environmental and economic efficiency of the implementation of ESG projects; $m_1 + m_2 + m_3 + m_4 = 1$;

i_H – index of the level of provision of the population with housing (at the end of the year);

i_{NF} – index of the number of employees who have improved their level of education or improve their qualifications on a permanent basis;

$i_{\text{р}}$ – index of labor productivity increase when using long-term motivation methods;

$i_{\Delta C}$ – index of reduction in the cost of treatment and maintenance of health.

3. The complex environmental index of socio-environmental and economic efficiency of the implementation of ESG projects is calculated according to formula 3:

$I_{\text{экол}} = \varphi_1 i_d + \varphi_2 i_{\text{эсп}} + \varphi_3 i_{\text{эсж}}$,

$\varphi_1, \varphi_2, \varphi_3$ – specific weights of the contribution of each chain index to the environmental complex index of socio-environmental and economic efficiency of the implementation of ESG projects;; $\varphi_1 + \varphi_2 + \varphi_3 = 1$;

$i_{d_{\text{э}}}$ – index of the share of environmentally friendly products output from the total volume of commissioning per year;

$i_{\text{эсп}}$ – index of ecologization of production processes;

$i_{\text{эсж}}$ – index of the share of ecologization of the living environment.

Next, the final comprehensive index of social, environmental and economic efficiency of the implementation of ESG projects is calculated.

$I_{\text{итог}} = \tau_1 I_{\text{эк}} + \tau_2 I_{\text{соц}} + \tau_3 I_{\text{экол}}$,

τ_1, τ_2, τ_3 – specific weights of the contribution of each complex index to the final complex index of social, environmental and economic efficiency of the implementation of ESG projects;

$\tau_1 + \tau_2 + \tau_3 = 1$.

Table 1: *Evaluation scale of complex indices for evaluation of social, environmental and economic efficiency of the implementation of ESG projects*

Index name	Meaning	Grade
Comprehensive economic index of socio-environmental and economic efficiency, $I_{эк}$	$I_{эк} \geq 1$	**great**
	$0,8 \leq I_{эк} < 1$	**good**
	$0,5 \leq I_{эк} < 0,8$	**satisfactorily**
	$I_{эк} < 0,5$	**unsatisfactory**
Comprehensive social index of socio-environmental and economic efficiency, $I_{соц}$	$I_{соц} \geq 1$	**great**
	$0,8 \leq I_{соц} < 1$	**good**
	$0,5 \leq I_{соц} < 0,8$	**satisfactorily**
	$I_{соц} < 0,5$	**unsatisfactory**
Comprehensive environmental index of socio-environmental and economic efficiency , $I_{экол}$	$I_{экол} \geq 1$	**great**
	$0,8 \leq I_{экол} < 1$	**good**
	$0,5 \leq I_{экол} < 0,8$	**satisfactorily**
	$I_{экол} < 0,5$	**unsatisfactory**
Final comprehensive index of socio-environmental and economic efficiency , $I_{итог}$	$I_{итог} \geq 1$	**great**
	$0,8 \leq I_{итог} < 1$	**good**
	$0,5 \leq I_{итог} < 0,8$	**satisfactorily**
	$I_{итог} < 0,5$	**unsatisfactory**

Conclusions

ESG standards should become part of the corporate culture, an element in shaping the mindset of employees. Understanding this will give companies new opportunities for development. The ESG agenda has the deepest roots that reflect the contradictions that humanity has accumulated to date and that need to be addressed.

As a result of the irregularity of the capitalist form of economic relations and the dominance of profit as the goal of activity, mankind has faced an extraordinary problem - the loss of nature. The problem of biodiversity loss is much larger than climate change. Scientists say the planet has entered its sixth mass extinction and nature is disappearing before our eyes. Only this process occurs through the fault of man. The solution to this problem reflects the environmental aspect of ESG standards.

Despite the most powerful geopolitical crisis in 2022, the ESG agenda in Russia continues to evolve, as evidenced by some facts:

1. Issues of green, social bonds took place, for example, they were issued by the largest issuers, VEB.RF, DOM.RF, Rostelecom, Atomenergoprom.
2. The volume of bank ESG loans, according to expert estimates, has grown.
3. The largest companies continue to disclose non-financial statements. Almost all companies that received the ESG rating came to its confirmation in 2022.
4. All issuers raising money through green, social, transitional bonds have fulfilled their obligations to place a report on the intended use of funds on the Moscow Exchange.

5. In 2022, the first deal with carbon units was made and the first verified climate project appeared. Despite the fact that only 20 carbon units were sold, this event demonstrated the readiness of the Russian carbon units market in terms of technical feasibility and availability of conditions for its further development.

6. The labor market is recovering from a turbulent downturn, and the demand for experienced graduates in sustainable development and ESG is gradually returning.

The main tasks for 2023 are: to gradually return the environmental decisions and requirements postponed due to the economic situation; adopt a federal law on non-public reporting with revised positions taking into account the new time; revision of corporate strategies for sustainable development in the direction of increasing attention to the problem of biodiversity reduction and loss of nature; ensuring transparency of the green portfolio of the banking market, the largest banks can agree on a voluntary reporting format to disclose the general parameters of the green or ESG portfolio by volume, dynamics, industry profiles.

So, the following year ESG will evolve further in various ways, penetrating deeper and deeper into all areas of human activity.

Abstract

In the context of global environmental challenges and the need for sustainable development, understanding the perception of sustainability becomes critical for the effective implementation of educational technologies. This paper explores how human factors such as cultural values, personal beliefs, motivation, and social environment influence students' perception of sustainability and their interaction with innovative educational technologies. The study analyzes various aspects, including psychological and sociocultural components, that shape students' attitudes toward sustainable practices and technologies. It examines factors that facilitate or hinder the adoption of sustainable concepts in educational platforms such as adaptive systems, online courses, and gamification. The results of the study show that positive perceptions of sustainability are associated with a high degree of engagement and awareness of individual responsibility for the environment. In addition, the cultural and social contexts in which students learn significantly influence their perception of sustainable practices and technologies. The paper highlights the need to integrate human factors into the development of educational programs and technologies aimed at sustainable development. Understanding these factors can help create more effective and inclusive educational systems that foster resilient behaviors and awareness in students.

Keywords: sustainable practices, adaptive learning systems, online courses, ecological awareness, behavioral change

I. Introduction

As the world grapples with pressing environmental challenges, the need for effective education on sustainability has never been more critical. Educational technologies, particularly innovative and adaptive systems, offer powerful tools for fostering understanding and engagement in sustainability among learners. However, the success of these technologies is significantly influenced by human factors—such as cultural values, personal beliefs, motivations, and social contexts—that shape individuals' perceptions of sustainability.

Understanding how human factors affect the perception of sustainability in educational settings is essential for designing effective curricula and technologies that resonate with diverse student populations. For instance, students' cultural backgrounds can greatly influence their attitudes toward environmental issues, impacting their receptiveness to sustainability concepts taught through technology. Personal beliefs about environmental responsibility and sustainability practices further complicate this dynamic, as they can either enhance or hinder engagement with educational content.

Moreover, motivation plays a pivotal role in shaping how students interact with educational technologies. Factors such as intrinsic motivation, relevance of the material to their lives, and social influences can affect students' willingness to engage with sustainability topics. Additionally, the social environment in which students learn, including peer interactions and community values, can significantly shape their perceptions and attitudes toward sustainability.

This paper seeks to explore the intricate relationship between human factors and the perception of sustainability in educational technologies. By examining how these factors influence learning experiences and outcomes, the research aims to provide insights that can enhance the development and implementation of educational technologies aimed at promoting sustainable practices. Ultimately, understanding this interplay is crucial for cultivating a generation of environmentally aware individuals capable of addressing the complex challenges posed by a rapidly changing world.

In addition to expanding access to education, educational technologies also improve the quality and relevance of learning. Tools such as AI-driven personalized learning platforms can adapt educational content to the specific needs and learning pace of individual students, enhancing engagement and retention of knowledge. By using data analytics and machine learning algorithms, these platforms can identify knowledge gaps and provide targeted interventions to improve learning outcomes. Moreover, virtual reality (VR) and augmented reality (AR) technologies are being used to create immersive learning environments that can simulate real-world scenarios, providing hands-on experience and fostering critical thinking, problem-solving, and creativity—skills that are increasingly important in the modern workforce.

The impact of innovative educational technologies is also visible in the corporate and industrial sectors, where continuous training and upskilling are necessary to keep pace with technological advancements. In many industries, workers are required to adapt to new tools, systems, and methodologies to remain competitive. Educational technologies, such as corporate e-learning programs and virtual training simulators, offer flexible, cost-effective solutions for upskilling employees without disrupting business operations. These tools enable workers to develop new competencies, increase their productivity, and contribute to the growth of their organizations, ultimately enhancing the overall competitiveness of a nation's workforce.

Despite the many advantages, integrating these technologies into education systems presents significant challenges. Infrastructure limitations, particularly in less developed regions, pose major obstacles to the widespread adoption of digital learning tools. Additionally, the digital divide, characterized by unequal access to technology and internet connectivity, can exacerbate inequalities in human capital development. Moreover, teachers and educators must be equipped with the necessary skills to effectively utilize these technologies in the classroom, which requires ongoing professional development and training. Furthermore, there are concerns about data privacy, the cost of implementing advanced technologies, and the need for policy frameworks that can support the integration of these tools into formal and informal education systems.

This study aims to explore the impact of innovative educational technologies on human capital development and, in turn, their role in promoting economic growth. It will analyze the ways in which these technologies are reshaping education and training systems globally, particularly in developing countries, where the need for human capital development is most urgent. By examining case studies, empirical data, and theoretical frameworks, this research seeks to highlight the potential of these technologies to bridge skill gaps, improve employability, and foster long-term economic growth. Additionally, it will address the challenges and opportunities associated with implementing these tools, emphasizing the importance of supportive infrastructure, policy frameworks, and investments in teacher training to maximize their effectiveness.

In conclusion, the rapid advancement of educational technologies presents a unique opportunity to revolutionize the development of human capital. As countries strive to remain competitive in the global economy, investing in these tools will be essential to building a highly skilled and adaptable workforce capable of driving innovation and economic growth. The integration of educational technologies into both formal education and lifelong learning systems will be a key determinant of future economic success, particularly in regions where traditional educational resources have been limited. By addressing the challenges of implementation and leveraging the full potential of these technologies, countries can unlock new pathways to economic development and global competitiveness.

II. Methods

This study employs a multi-method approach to analyze the impact of innovative educational technologies on human capital development and their contribution to economic growth. The research methodology is divided into three main components: literature review, quantitative analysis, and case study analysis. Each of these methods provides distinct insights and complements the overall understanding of how educational technologies influence human capital development.

1. Literature Review:

The first phase of the study involves conducting a comprehensive literature review to explore existing research on the relationship between educational technologies, human capital development, and economic growth. This review focuses on academic publications, reports from international organizations, and policy documents that discuss the role of technology in education. By synthesizing previous studies, this method identifies key theoretical frameworks and empirical findings that serve as a foundation for the current analysis.

The literature review also examines various types of educational technologies—such as e-learning platforms, artificial intelligence-driven systems, virtual reality, and gamification—and their effectiveness in different contexts. Special attention is paid to research exploring the use of these technologies in developing countries, where challenges such as limited infrastructure and unequal access to technology may affect their impact. This review highlights gaps in existing knowledge and suggests areas where further research is needed, laying the groundwork for subsequent quantitative and case study analyses.

2. Quantitative Analysis:

The second method involves quantitative analysis using secondary data from reputable sources such as the World Bank, UNESCO, and the Global Competitiveness Index (GCI). This analysis investigates the relationship between human capital development indicators—such as education levels, workforce skills, and technological adoption—and economic growth across different countries.

Key variables considered include:

- Educational attainment levels (e.g., literacy rates, enrollment in primary, secondary, and tertiary education).
- Human capital investment (e.g., government expenditure on education and training).
- Technological integration in education (e.g., percentage of schools with internet access, use of e-learning platforms).
- Economic indicators (e.g., GDP growth, productivity rates, employment levels).

Using statistical tools such as regression analysis and correlation coefficients, the study examines the extent to which the adoption of educational technologies correlates with improvements in human capital and economic performance. Additionally, longitudinal data are used to assess trends over time, allowing for a deeper understanding of how technological advancements in education contribute to sustained economic growth. The quantitative analysis also accounts for regional disparities, providing insights into how developing and developed countries experience different outcomes from technological integration in education.

3. Case Study Analysis:

The third method is qualitative case study analysis, which focuses on specific countries or regions that have successfully implemented innovative educational technologies to improve human capital development. These case studies provide detailed insights into the practical challenges, successes, and lessons learned from the adoption of technology-driven education systems.

The selected case studies include countries with varying levels of economic development and technological infrastructure, such as:

- Singapore, known for its high level of human capital investment and advanced use of e-learning and AI-driven educational tools.
- Estonia, a leader in digital education and online learning, which has transformed its education system using technological innovation.
- Kenya, where mobile learning initiatives and online platforms are bridging education gaps, particularly in rural and underserved areas.

Each case study examines key factors such as government policies, infrastructure investments, teacher training programs, and public-private partnerships that have facilitated the successful integration of educational technologies. The case studies also highlight the socioeconomic impact of these initiatives, particularly in improving access to education, enhancing employability, and fostering long-term economic growth. Through a comparative analysis of these cases, the study identifies best practices and policy recommendations that can inform future efforts to leverage educational technologies for human capital development in other regions.

III. Results

The exploration of the influence of human factors on the perception of sustainability in educational technologies yielded several significant findings. These results highlight the complexities of integrating sustainability education into technology-mediated learning environments and underscore the importance of considering human factors in the design and implementation of these technologies.

1. Impact of Cultural Values on Sustainability Perception

Students from diverse cultural backgrounds demonstrated varying levels of awareness and concern regarding sustainability issues. The study revealed that cultural values significantly shape students' perceptions of environmental responsibility. For instance, students from cultures with strong traditions of conservation and communal living exhibited a heightened sense of stewardship toward the environment. In contrast, those from cultures with less emphasis on sustainability reported lower levels of engagement with related educational technologies.

2. Role of Personal Beliefs and Attitudes

Personal beliefs about environmental issues were found to be a strong predictor of students' willingness to engage with sustainability content. Survey data indicated that students who identified as environmentally conscious were more likely to participate actively in courses focused on sustainability. Conversely, those who expressed skepticism about environmental problems tended to disengage from educational technologies designed to promote sustainability, highlighting the need for approaches that address these beliefs.

3. Motivation and Engagement Levels

Motivational factors were crucial in determining students' engagement with educational technologies focused on sustainability. The findings showed that intrinsic motivation—driven by personal interest and relevance of the material—correlated positively with higher levels of engagement and knowledge retention. For example, students who perceived sustainability topics as personally relevant were more likely to interact with adaptive learning systems and complete online courses. Additionally, extrinsic motivators, such as grades and social recognition, also played a role, but to a lesser extent.

4. Influence of Social Environment

The social environment, including peer influence and community values, emerged as a significant factor affecting students' perceptions of sustainability. Students reported feeling more motivated to engage with sustainability education when they were part of supportive peer groups that emphasized environmental consciousness. Furthermore, community initiatives promoting sustainability positively impacted students' perceptions, leading to increased participation in educational technologies designed to enhance their understanding of sustainable practices.

5. Technological Interaction Patterns

Analysis of interaction data from adaptive learning systems revealed patterns in how different student groups engaged with sustainability content. Students with a strong interest in environmental issues utilized interactive features—such as simulations and gamified elements—more frequently, which facilitated deeper learning and application of sustainable practices. In contrast, students with lower interest levels tended to utilize only basic features, indicating a missed opportunity for more profound engagement with the material.

These results underscore the critical role of human factors in shaping perceptions of sustainability within educational technologies. By acknowledging and addressing cultural values, personal beliefs, motivations, and social environments, educators and developers can create more effective and inclusive learning experiences that resonate with diverse student populations. This understanding is vital for fostering a generation of environmentally aware individuals equipped to address the pressing challenges of sustainability in the modern world.

The motivation behind global educational reforms is largely driven by the development of innovative educational technologies, which aim to enhance higher education, foster economic growth, and transform education into an innovation-oriented space. These reforms align with market-driven economic principles, democratic values, and global advancements in science and technology by reshaping the educational process and updating content, leading to the accelerated growth of education. The integration of these technologies ensures the competitiveness of higher education institutions in the educational services market and contributes to improving the quality of education.

Innovative educational technologies, which encompass both formal and informal learning methods, focus on enhancing educational outcomes and achieving core educational objectives. The progression of a specialist's training through these technologies can be categorized into four levels: existing education, direct training in an innovative environment, testing of educational outcomes using modern methods, and implementing educational results through innovative technologies.

Various groups of innovative educational technologies have been identified:

- **Digital technologies**: These play a central role in the digital transformation of education, fostering a specialist's digital culture and improving motivation and productivity through the inclusion of digital tools and professional software in curricula.
- **Quality management and information support**: These innovations provide tools for monitoring and controlling the educational process, aiding in the development of both individuals and institutions.
- **Person-centered technologies**: Focus on creating a safe, conflict-free educational environment that prioritizes individual development and the realization of human potential.
- **Educational and didactic technologies**: These methods include group work, independent

learning, project-based learning, and interactive techniques such as games and audiovisual tools, all aimed at enhancing the educational process.

Innovative pedagogical methods have also become widespread, emphasizing real-world professional activity, interactivity, and advanced technologies like simulation, group training, and video learning. Additional modern tools include e-learning, anticipatory learning, and the use of various digital platforms for communication, such as forums, video conferences, and multimedia. Furthermore, the technological infrastructure of higher education institutions—such as internet access and computer labs—plays a crucial role in fostering innovation and supporting the creative endeavors of both students and teachers.

IV. Discussion

The features of innovative education play a crucial role in enhancing higher education and producing competitive specialists. These features should be considered in the learning process, and include:

- Openness to the future in innovative higher education;
- Focus on predicting and programming personal development;
- Emphasis on a person-centered approach and human development;
- Building partnerships using innovative educational technologies, fostering mutual assistance, collaboration, and co-creation;
- Integration of creativity into higher education;
- Acknowledgment of the instability and constant contradictions in the educational system and individuals.

The systematic application of innovative educational technologies by teachers is essential for improving higher education today. The more diverse teaching methods and strategies a teacher utilizes, the better they can motivate learners, making classes more engaging and effective. This approach encourages solving non-standard problems, facilitates practical learning, and ensures the mastery of innovative professional skills. A competitive specialist continuously hones their teaching skills, adopts innovative strategies, and selects new technologies and methods.

The findings of this study highlight the intricate relationship between human factors and the perception of sustainability within educational technologies. Understanding these dynamics is crucial for educators, curriculum developers, and technology designers aiming to promote sustainable practices effectively. This discussion will explore the implications of the results, potential strategies for improving educational outcomes, and areas for future research.

1. Cultural Values and Sustainability Education

The strong influence of cultural values on students' perceptions of sustainability emphasizes the need for culturally responsive educational practices. Educational technologies should be designed to incorporate local contexts and cultural narratives related to sustainability. By acknowledging the cultural backgrounds of students, educators can create more relevant and engaging learning experiences. For instance, integrating examples of local environmental issues or traditional practices of conservation can resonate more deeply with students, fostering a sense of connection and responsibility toward their environment.

2. Addressing Personal Beliefs and Attitudes

The study revealed that personal beliefs significantly impact engagement with sustainability topics. To enhance participation, it is essential to address skepticism and misinformation about environmental issues. Educational technologies can include features that provide evidence-based information, countering misconceptions and fostering critical thinking. For example, interactive modules that simulate environmental impacts can illustrate the consequences of unsustainable practices, helping students to see the relevance of sustainability in their lives. Additionally, incorporating narratives of successful sustainability initiatives may inspire positive attitudes and encourage proactive behavior.

3. Enhancing Motivation through Personalization

Motivational factors play a critical role in determining student engagement levels. The findings suggest that personalized learning experiences can enhance intrinsic motivation and lead to greater engagement with sustainability content. Adaptive educational technologies that tailor content to individual interests and prior knowledge can create a more compelling learning environment. Moreover, incorporating gamification elements, such as rewards for sustainable actions or competitions among peers, can provide extrinsic motivation that complements intrinsic interest, making learning more enjoyable and impactful.

4. Leveraging the Social Environment

The positive influence of the social environment on perceptions of sustainability indicates that collaborative learning strategies can enhance engagement with sustainability topics. Group projects, peer discussions, and community-based initiatives can foster a sense of belonging and shared responsibility. Educational technologies can facilitate these collaborative efforts by enabling students to connect with each other and engage in collective problem-solving activities related to sustainability. Online forums and social media integrations can provide platforms for students to share experiences, exchange ideas, and support one another in adopting sustainable practices.

5. Implications for Technology Design

The study's results underscore the importance of designing educational technologies that take human factors into account. Developers should prioritize user experience and ensure that technological features align with the motivations and needs of diverse learners. This may involve incorporating flexible learning paths, interactive content, and opportunities for self-directed learning. Additionally, ensuring accessibility for all students, including those with varying levels of technological proficiency, is crucial for maximizing engagement and effectiveness.

6. Future Research Directions

While this study provides valuable insights, further research is needed to explore the longitudinal effects of educational technologies on sustainability perceptions and behaviors. Future studies could investigate how different demographic factors, such as age, gender, and socioeconomic status, influence engagement with sustainability education. Additionally, examining the impact of hybrid learning environments, which combine in-person and online instruction, could provide further understanding of how human factors interact with educational technologies.

Abstract

This paper explores various economic models and strategies that have successfully facilitated transitions toward sustainable development in different regions around the world. By analyzing the mechanisms employed in these transitions, the study identifies key economic, policy, and institutional factors that contributed to success. The analysis spans different sectors, including energy, agriculture, and manufacturing, with a focus on green technologies, circular economy practices, and renewable energy integration. The paper also reviews international cooperation efforts, regulatory frameworks, and the role of innovation in driving sustainable growth. The findings suggest that a combination of public policy incentives, private sector engagement, and social inclusivity is crucial for achieving long-term sustainability. Case studies of countries such as Sweden, Germany, Costa Rica, and China illustrate the diversity of approaches and the lessons that can be drawn from them. The research contributes to a better understanding of the pathways and tools necessary for a global transition toward a sustainable economic model.

Keywords: green economy, circular economy, renewable energy, policy incentives, innovation, international cooperation, environmental sustainability, transition strategies

I. Introduction

In recent decades, the global community has increasingly acknowledged the necessity of sustainable development as a fundamental principle for economic growth. Sustainable development involves pursuing economic progress while addressing environmental protection and social equity, ensuring the well-being of both current and future generations. As societies face the impacts of climate change, resource depletion, and social inequality, understanding the economics of sustainable development has become critical. This research paper explores the complex interaction between economic principles and sustainable development goals, highlighting the challenges impeding progress and examining potential solutions. By synthesizing existing literature and empirical evidence, the paper aims to illuminate the intricacies of achieving sustainable development from an economic standpoint. The urgency of addressing sustainability issues is evident in the rising frequency of environmental disasters, increasing income inequality, and ecosystem degradation. In this context, policymakers, businesses, and civil society are being urged to adopt comprehensive approaches that balance economic growth with environmental care and social inclusivity. Through a multidisciplinary perspective, this paper seeks to dissect the economics of sustainable development, shedding light on the trade-offs, synergies, and policy measures required to build a more equitable and resilient future. By critically examining existing frameworks, identifying knowledge gaps, and proposing innovative strategies, this paper aims to contribute to the ongoing dialogue on sustainable development and stimulate action toward a more sustainable and prosperous world. Sustainable development has become a critical concern in today's world, as societies face the pressing challenge of balancing economic growth with environmental protection and social equity. Popularized by the Brundtland Commission in 1987, sustainable development is defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." Since then, it has served as a guiding framework for governments, businesses, and communities worldwide. The pursuit of sustainable development is complex, involving the interconnectedness of economic, environmental, and social factors. Economists play a key role in addressing these challenges by analyzing trade-offs, creating incentives, and developing policy frameworks to support sustainable practices. The economics of sustainable development covers a broad spectrum of topics, including resource management, the transition to clean energy, poverty reduction, and climate adaptation. Despite widespread acknowledgment of the need for sustainability, significant challenges remain. Economic systems often prioritize immediate profits over long-term sustainability, leading to resource depletion, worsening inequality, and environmental degradation. Furthermore, many sustainability issues are global in scope, requiring international collaboration, which is often hindered by political and economic conflicts. In this context, the demand for innovative solutions is more urgent than ever. This review paper aims to provide an in-depth exploration of the economics of sustainable development, focusing on the obstacles to achieving sustainability and the possible ways forward. By integrating existing research and identifying areas where further study is needed, the paper seeks to enhance understanding of the economic forces at play in sustainable development and to guide the creation of policies that foster a more inclusive, resilient, and environmentally conscious global economy.

II. Methods

This paper employs a qualitative research design to investigate the economics of sustainable development, focusing on identifying challenges and exploring potential solutions. Qualitative methods are particularly well-suited for an in-depth analysis of the complex interactions between economic factors and sustainable development objectives, allowing for a nuanced understanding of the topic.

Data will be collected through an extensive literature review, drawing from academic journals, books, reports, and other scholarly materials that address the economics of sustainable development. The review will utilize online databases such as Google Scholar, JSTOR, and PubMed to access relevant research. Additionally, reports from governmental and non-governmental organizations, as well as industry white papers, will be included to provide a broad perspective on the subject.

The inclusion criteria for the literature review will focus on sources that discuss key aspects of sustainable development economics, such as economic growth, environmental sustainability, social equity, poverty reduction, and technological innovation. Only peer-reviewed articles and reputable sources published within the last ten years will be considered to ensure that the research is both up-to-date and credible. Exclusion criteria will include studies that do not directly address the economics of sustainable development or lack empirical evidence to support their findings. Non-English language publications will be excluded due to language constraints.

Ethical considerations in this research involve proper citation and acknowledgment of all sources to avoid plagiarism. The accuracy and relevance of the information will be critically assessed, with attention given to respecting diverse viewpoints in the literature. Care will be taken to avoid bias in both the selection and interpretation of data, ensuring an objective and balanced analysis of the economics of sustainable development.

III. Results

A series of recent crises and growing instability in the global economy and politics, as well as an increasing number of global risks and challenges, force us to reconsider the concept of sustainable development. Previously perceived as an abstract theoretical construct, the system of global goals and objectives that seemed distant from everyday problems has been seriously tested for viability and relevance in recent years. For everyone who has lived through the COVID-19 pandemic with its profound socio-economic consequences, and who is now observing fundamental changes in the economy and geopolitics, the term "sustainable development" takes on new meaning and significance.

Attempts to question the need to follow the UN Agenda for Sustainable Development until 2030, adopted in 2015, against the backdrop of intensifying crises have quickly given way to an awareness of the importance of joining forces to achieve the 17 Sustainable Development Goals (SDGs). This requires efforts at all levels - from states and regional associations to municipalities, companies and individuals representing society as a whole.

Increased attention to the topic of sustainable development is also due to worsening climate problems. Experts once again emphasize the imbalance in the climate system and the onset of irreversible consequences for the climate. Global environmental and climate risks have been leading the annual World Economic Forum (WEF) global risk reports for several years in a row, which only confirms the need for urgent action.

IV. Discussion

The concept of sustainable development is a process of economic and social transformation, in which the use of natural resources, investment direction, scientific and technological progress, personal development and institutional changes are coordinated in such a way as to strengthen the current and future potential to meet human needs and aspirations. At the corporate level, this concept covers a system of principles, processes and results aimed at maintaining a balance between economic, environmental and social aspects both in companies and in society as a whole. Maintaining this balance contributes to the preservation of vital systems and long-term well-being. The concept is closely related to the ESG approach (environmental, social, governance - the environment, society and corporate governance), which is aimed at managing non-financial risks taking into account the impact on the environment, society and the principles of effective management. This approach includes such processes as ESG rating, ESG investing and ESG transformation, and represents a continuous improvement of business processes. Current economic and political crises have only increased the importance of strengthening the sustainability of companies and made it urgent to develop more relevant ESG criteria for long-term development.

In the post-pandemic era, not only institutional investors, but also politicians in developed countries are declaring their commitment to ESG principles, paying attention to the implementation of "green" technologies, human-oriented corporate practices and improving the quality of life. The concept of the "green" economy, which emerged at the end of the 20th century, remains important, focusing on the need to minimize the negative impact of economic activity on the environment, placing sustainable development and environmental safety above simple economic growth at any cost.

The process of aligning the Decision Support System (DSS) to sectoral modeling varies based on the capabilities and flexibility of the selected modeling methodology. This section, along with the following one, details how this alignment is conducted for the Global Energy Model (GEM).

The integration of thematic results into GEM, as well as the alignment of outcomes, is influenced by the degree to which each sector experiences endogenous feedback loops.

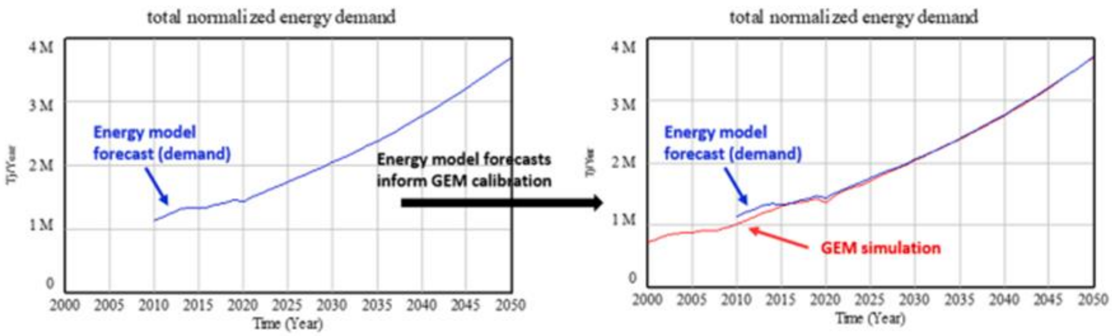

Figure 1: *Illustration of reference mode and the alignment of behavior in GEM*

Soft Coupling of Methods

The soft coupling of methods can be achieved either through direct input or calibration:

- Direct Input: This involves importing the results from thematic modeling as data time series into GEM. When there is limited or no relevant structure in GEM or when the parameters are not influenced by endogenous feedbacks, the outputs from sectoral models are fed into time-based table functions within GEM.
- Calibration: This approach is utilized to align GEM results with sectoral modeling outputs when the relevant indicators are influenced by GEM's endogenous feedback structure. Calibration requires several steps, which will be demonstrated using the example of total energy demand.

Steps for Calibration

1. Creating an Artificial Simulation:
   - The first step involves generating a simulation specifically for calibration purposes. In this case, the energy demand data for alignment is sourced from the Low Emissions Analysis Platform (LEAP) (SEI, 2018).
   - The System Dynamics (SD) modeling software enables the importation of data from sectoral models into GEM and the creation of a simulation file that can be visualized. This imported data is termed "reference modes" and is utilized to conduct behavioral validation tests.
   - The left graphs in Figure 3 illustrate the reference data from the LEAP model, specifically total energy demand and energy-related CO2e emissions, which are essential for calibrating these parameters within GEM.
2. Importing Baseline Real GDP Data:

Since LEAP does not account for feedback mechanisms affecting macroeconomic productivity, baseline real GDP data is imported as time series. This is necessary because GEM incorporates feedback loops that treat real GDP as a driver of energy demand and related costs. These factors subsequently impact sectoral real GDP through total factor productivity.

The interplay between real GDP and energy demand is reciprocal; thus, a change in real GDP influences energy demand and vice versa. To facilitate calibration of GEM in line with LEAP projections, it is crucial that real GDP remains exogenous during the calibration process to replicate the conditions (ceteris paribus) present in the LEAP model.

This calibration process ensures that the energy demand and CO2e emissions in GEM are accurately aligned with the projections and feedback mechanisms represented in the LEAP model, thereby enhancing the reliability of the model's outputs.

The events of 2022–2023 are increasingly raising doubts about the comprehensive achievement of the Sustainable Development Goals (SDGs) within the framework of Eurasian integration. The destruction of supply chains, rising prices for raw materials and commodities, including food, are creating difficult conditions for achieving the SDGs, especially those related to ending hunger (SDG 2) and ensuring health and well-being (SDG 3). Sergey Glazyev, Minister for Integration and Macroeconomics of the EEC, notes the trend towards chaos in food markets, emphasizing that global resources and technologies make it possible to produce food for 20 billion people — twice as many as the current population of the planet. However, the problem lies in the unfair distribution of resources, unequal international economic relations, and rising prices caused by the quantitative easing policy of reserve currency issuers.

For an effective transition to sustainable development, it is necessary to develop an adequate system of goals and indicators. It is necessary to improve the methodology for selecting statistical indicators reflecting the achievement of SDGs in the EAEU countries, as well as to create new indicators for missing areas. It is also important to implement international standards and take into account recommendations, such as the OECD recommendations, to improve the quality and comparability of economic statistics. This is critical for the formation of the EEC's own dossier on sustainable development and the preparation of a new report. Of particular importance is the coordination of statistical activities in the EAEU region, strengthening professional and research potential, as well as the introduction of advanced international standards in methodology and data classification.

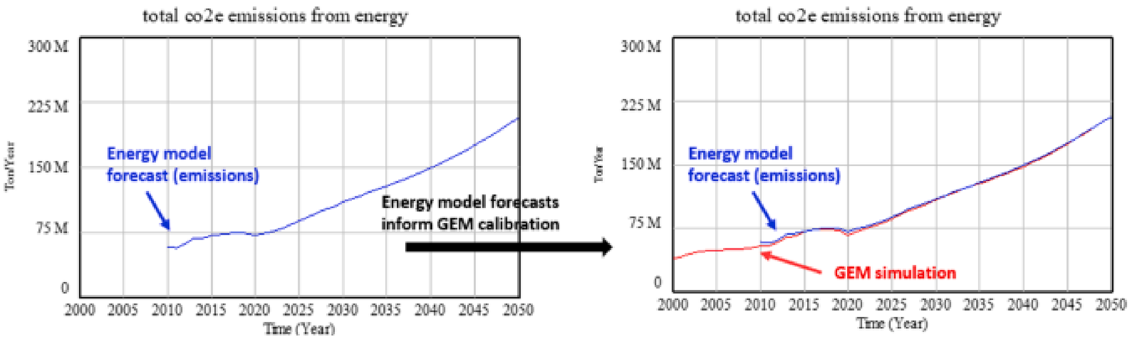

Figure 2: *Illustration of reference mode and the alignment of behavior in GEM*

The demand aligns with the results from LEAP, and closing the endogenous feedback loops enables us to (i) examine how macroeconomic indicators evolve under LEAP projections and (ii) subsequently adjust the energy demand trajectory forecasted by LEAP. Figure 4 illustrates a comparison of simulations with and without the endogenous feedback effects through total real GDP. The findings indicate that the energy mix derived from the sectoral model contributes to increased economic growth (for instance, through lower costs). This additional growth results in greater energy demand and related emissions than what LEAP initially predicted.

This process is conducive to iterations. Specifically, the updated total real GDP forecast from GEM can be integrated back into LEAP. This integration aids in assessing whether the anticipated emission reductions remain achievable or if the increased demand necessitates more robust mitigation efforts. This methodology is applied across all modules except for ecosystem service provisioning. The exception arises because modeling current and future ecosystem service provisioning requires iterative processes among GEM, GIS, and ecosystem services models like InVEST.

Abstract

Carbon taxes and trading schemes are pivotal instruments in the fight against climate change, aimed at reducing CO2 emissions by providing economic incentives for emission reductions. This paper examines the effectiveness of these mechanisms in various contexts, analyzing their design, implementation, and outcomes across different regions and industries. Carbon taxes impose a direct cost on carbon emissions, encouraging businesses and consumers to reduce their carbon footprint, while cap-and-trade systems set a limit on total emissions and allow for the trading of emission permits. The analysis highlights the strengths and weaknesses of each approach, including their economic impacts, environmental effectiveness, and equity considerations. The findings suggest that both carbon taxes and trading schemes can significantly contribute to emission reductions when designed with careful consideration of local economic conditions and social implications. The paper concludes with recommendations for policymakers to enhance the effectiveness of these tools in achieving climate targets.

Keywords: carbon tax, cap-and-trade, CO2 emissions, climate change, emission reduction, environmental policy

I. Introduction

Climate change represents one of the most pressing challenges of our time, driven primarily by anthropogenic greenhouse gas (GHG) emissions. The escalating impacts of climate change—ranging from extreme weather events to rising sea levels—underscore the urgency for effective policy measures to mitigate these effects. Economic theories regarding externalities provide a foundational framework for understanding the role of market failures in exacerbating environmental degradation. In the early 20th century, economist Arthur Pigou introduced the concept of externality, which refers to costs or benefits resulting from an action that are not accounted for by the producer. For instance, the combustion of fossil fuels not only generates energy but also releases harmful emissions, imposing significant social costs on society that far exceed the private costs incurred by producers.

As the global community grapples with the challenges posed by climate change, policymakers have increasingly turned to market-based mechanisms, such as carbon taxes and emissions trading systems (ETSs), as strategies for reducing GHG emissions. These tools are designed to internalize the external costs associated with carbon emissions, thereby creating economic incentives for businesses and consumers to shift towards cleaner alternatives. The Pigovian tax, named after Pigou, is one such approach that aims to align private costs with social costs, thereby promoting more efficient resource allocation and encouraging sustainable practices.

Despite their theoretical appeal, the implementation of carbon taxes and ETSs has sparked considerable debate regarding their effectiveness, equity, and economic impacts. Critics argue that the costs associated with these policies can disproportionately burden vulnerable populations and that the actual reductions in emissions may fall short of established targets. Conversely, proponents assert that when designed and implemented correctly, these policies can drive significant reductions in GHG emissions while fostering innovation in clean technologies.

This study aims to critically examine the effectiveness of carbon taxes and emissions trading schemes in mitigating climate change by reviewing contemporary empirical and theoretical research on these market-based instruments. By investigating their design, implementation, and outcomes, the paper seeks to provide a comprehensive understanding of how these policies can be optimized to achieve climate goals. The following sections will outline the economic theory underpinning these instruments, discuss their design considerations, evaluate their practical implementation, and analyze their effectiveness in reducing emissions and their broader economic implications. Ultimately, this research aspires to identify best practices and inform policy design that enhances global efforts to combat climate change.

The economic and environmental effects of climate change and associated policies have emerged as a significant topic of international policy discussions over recent decades. In 2015, at the United Nations (UN) Climate Change Conference (COP21), 196 parties reached a consensus on a legally binding global treaty, known as the Paris Agreement (The Paris Agreement | UNFCCC). This agreement primarily aims to limit the increase in global average temperature to well below 2°C above pre-industrial levels while striving to keep the rise to 1.5°C. However, a 2023 report by UNFCCC indicates that the world is currently not on track to meet the goals set forth in the Paris Agreement, highlighting the urgent need for additional action to reduce global greenhouse gas (GHG) emissions and achieve net-zero emissions by 2050. This shortfall is evident despite the introduction of over 70 carbon-related policies by 2024, which include 39 carbon taxes and 36 emissions trading systems (ETSs) implemented across various national and subnational jurisdictions worldwide. This situation raises critical questions about the effectiveness of these policies: Are carbon taxes and ETSs effective in curbing GHG emissions? Which of the two policies has yielded the best results? Can the effectiveness of these policies be enhanced? What are the economic implications of such policies? To address these inquiries, this study provides a thorough review of contemporary empirical and theoretical research analyzing the impact of the two primary market-based instruments—carbon taxes and ETSs—on global environmental and economic conditions.

A carbon tax is a price-control mechanism that internalizes the external costs associated with carbon emissions by imposing a direct charge on emissions. In contrast, an ETS is a quantity-control mechanism aimed at reducing carbon emissions by establishing a cap on the total allowable GHG emissions for each period. Both systems are designed to increase the relative cost of producing goods that emit GHGs compared to those that do not, thereby decreasing the incentive to produce GHG-emitting products. Although other ad valorem taxes, such as fuel or value-added taxes, may also influence the relative pricing of GHG emissions, these taxes are primarily implemented to generate government revenue rather than to reduce emissions. Consequently, few studies have attempted to quantify the environmental and economic impacts of such ad valorem taxes across different countries. This review, therefore, focuses on the effects of carbon taxes and ETSs, specifically emphasizing their role in reducing GHG emissions rather than merely increasing government revenue. By conducting a systematic literature review of empirical outcomes and theoretical insights regarding the impact of these instruments on environmental and economic conditions, this study aims to synthesize research findings in both physical and economic sciences. This work also integrates and updates existing information about the environmental impacts of carbon pricing mechanisms and their economic consequences. A key distinction from previous reviews is that this study comprehensively covers both carbon taxation and ETSs, analyzing their relative effects rather than examining a single policy tool in isolation. By doing so, we aim to identify best practices and inform policy design that can ultimately enhance global efforts to combat climate change.

The remainder of this paper is organized as follows: Section 2 outlines the economic theory underlying carbon tax and ETS policies. Section 3 discusses the design considerations for each policy. Section 4 explores the practical implementation of these policies. Section 5 assesses the effectiveness of the policies in reducing emissions and their economic impacts. Sections 6 and 7 compare carbon taxes and ETSs and discuss potential policy integration. Finally, Section 8 summarizes our conclusions and offers suggestions for future research.

II. Methods

This study utilizes three specific methods to evaluate the effectiveness of carbon taxes and emissions trading systems (ETSs) in reducing greenhouse gas (GHG) emissions:

1. **Systematic Literature Review**:
   - A systematic literature review was conducted to collect and analyze empirical studies and theoretical papers focusing on carbon taxes and ETSs. The review involved searching databases such as JSTOR, Google Scholar, and ScienceDirect for relevant articles published from 2000 to 2024.
   - The inclusion criteria prioritized peer-reviewed articles that assess the impact of these policies on GHG emissions and their economic implications. Studies were categorized based on their findings related to effectiveness, economic impact, and social equity.
   - This method allowed for the identification of trends, common themes, and gaps in existing research, enabling a comprehensive understanding of the current state of knowledge regarding carbon pricing mechanisms.
2. **Case Study Analysis**:
   - The study analyzed specific case studies from countries and regions that have implemented carbon taxes and ETSs, such as Sweden, the European Union, and California.
   - Each case study focused on the design and implementation of the policy, the context in which it was applied, and the measurable outcomes in terms of GHG emissions reductions and economic effects.
   - This method provided practical insights into the real-world application of carbon pricing mechanisms, illustrating the challenges and successes experienced in different geographical and political contexts.
3. **Comparative Policy Analysis**:

   A comparative analysis was performed to evaluate the effectiveness of carbon taxes versus ETSs. This involved assessing various dimensions, such as:
   - **Emission Reduction Targets**: Comparing the actual GHG reductions achieved by each policy type.
   - **Economic Impact**: Analyzing how each policy affects economic growth, industry competitiveness, and employment levels.
   - **Social Equity**: Evaluating the distributional impacts of these policies on different socioeconomic groups.

   This method enabled the identification of best practices and lessons learned from each policy approach, facilitating recommendations for enhancing the effectiveness of carbon pricing mechanisms.

By employing these methods, the study aims to provide a detailed analysis of how carbon taxes and emissions trading systems function in practice and their effectiveness in addressing climate change.

III. Results

In the 20th century, economist Arthur Pigou first introduced the concept of externality, which refers to costs or benefits that arise from an action but are not borne by the producer of that action. A clear example of this is climate change, where energy use and industrial processes contribute to anthropogenic climate change through greenhouse gas (GHG) emissions, representing a negative externality. In such scenarios, the marginal social cost incurred by society is significantly greater than the marginal private cost of production experienced by a firm, leading to a market failure where the optimal quantity of production exceeds the socially optimal quantity. Pigou proposed that policymakers could rectify this market failure by imposing a tax on market activities that reflects the social damage caused, known as a Pigovian tax.

Figure 1 illustrates a typical Pigouvian tax, where the private marginal benefit of consuming goods declines as the quantity demanded increases, while the private marginal cost of supplying goods rises with the quantity supplied. An efficient market achieves equilibrium when private marginal benefits equal private marginal costs, occurring at the quantity q_{market} and price p_{market} shown in the figure. However, when a good's consumption generates negative externalities—such as air pollution from fossil fuel consumption—the social marginal cost reflects the marginal external cost in addition to the private marginal cost of supply. A "social marginal cost" line represents this cumulative cost, illustrating how the externality can be internalized by imposing a tax on the purchase of the good (indicated by the line representing private marginal cost plus tax). The tax rate is set to equal the marginal external cost, aligning with the social optimum. This taxation shifts the market equilibrium to the optimal point $q_{optimum}$.

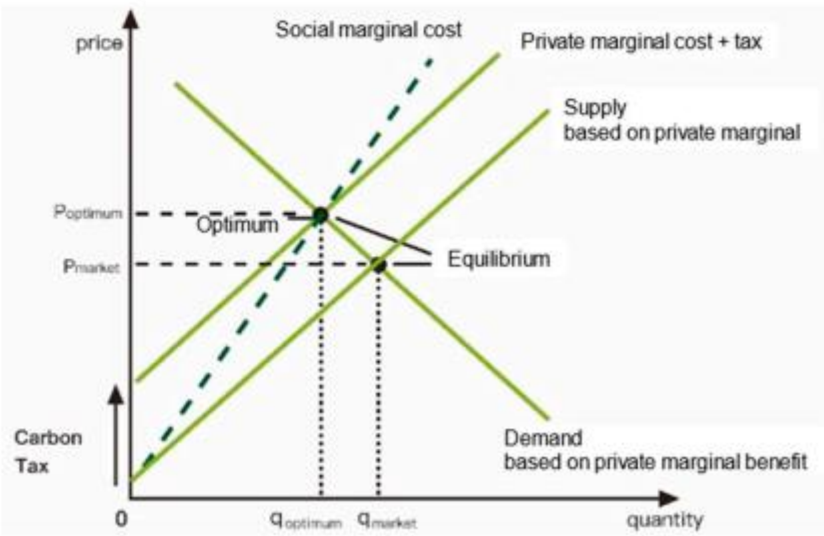

Figure 1: *Pigouvian tax*

Carbon taxes, as a first-best or optimal solution to address the negative externalities associated with anthropogenic carbon dioxide emissions, have become a preferred policy in many countries pursuing ambitious climate goals. However, these taxes face criticism. Early theoretical and practical discussions regarding the identification of social costs, as well as the costs of misallocation linked to market intervention versus maintaining the status quo, were explored by prominent 20th-century economists such as Coase, Hayek, Ostrom, and Baumol. More recently, political economy literature has associated carbon taxes with climate capitalism, while narrow, discipline-specific perspectives have led to the emergence of technocentric and economistic viewpoints.

The theoretical foundations of emissions trading systems (ETS) can be traced back to the research of Nobel Prize laureate Ronald Coase. Coase posited that when trade in externalities, such as greenhouse gas (GHG) emissions, is feasible and transaction costs are low, bargaining among parties will lead to a Pareto efficient outcome, regardless of the initial distribution of property rights. This principle, now known as the Coase Theorem, suggests that government intervention can mitigate market failures arising from negative externalities by clearly defining property rights.

As depicted in Fig. 2, when a cap on emissions is established, it imposes a hard limit on the market supply, rendering the supply curve inelastic and unresponsive to price fluctuations as seen in traditional supply-demand models. The new equilibrium is determined by the cap, resulting in a $q_{constrained}$ and an increase in the price $p_{optimum/}$

Building on these principles, Dales introduced the concept of property rights within the context of pollution control in 1968 by formalizing an Emissions Trading Program, which has since become the foundation of contemporary ETSs. Under this framework, entities granted the right to emit GHGs can do so, provided they comply with specific legal conditions. Legally, emissions rights are treated as limited-use rights associated with environmental resources, conceptualizing the environment as a tradable commodity with the government as the ultimate proprietor.

In this system, the government allocates a fixed quantity of emissions rights to firms, permitting them to emit GHGs during their production processes. Moreover, by facilitating the trading of these rights under regulatory conditions, emissions effectively become a tradable commodity. Firms facing higher marginal costs for pollution can purchase emissions rights from those with lower emission costs. Consequently, this cap-and-trade market structure fosters a Pareto-optimal allocation, minimizing total emissions costs while capping the overall volume of GHG emissions produced in the market.

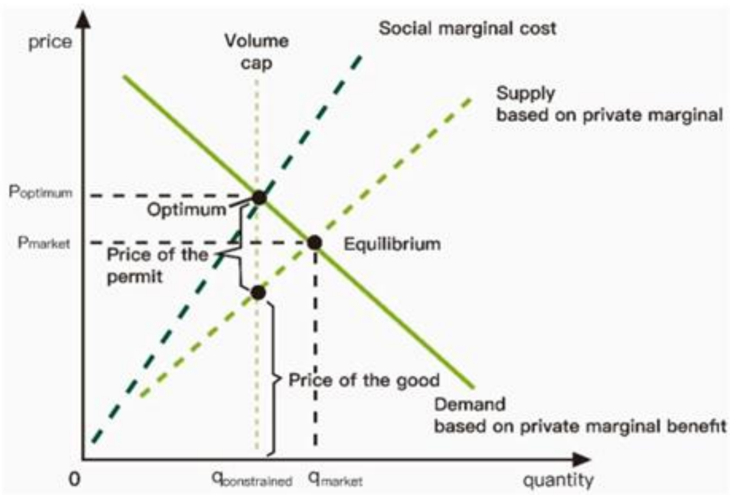

Figure 2: *Coasian model*

IV. Discussion

After determining the emissions cap, policymakers must decide how to allocate pollution permits under the emissions trading system (ETS). There are two primary allowance allocation schemes used to date: free allocation and public auction.
The main advantages of free allocation include zero transaction costs and the potential for equitable distribution of permits, resulting in low resistance to execution and ease of

implementation. This method has often been employed during the initial pilot stages of ETSs. Common approaches for permit distribution include:

- Grandfathering: Allocating permits based on historical emissions.
- Output-Based Allocation: Assigning permits according to current emissions.
- Fixed-Sector Benchmarking: A combination of historical and current emissions for allocation.

However, research indicates that grandfathering may undermine ETS efficiency due to inadequate financial support for system operation. Consequently, some studies have suggested employing formal pricing and auction methods to improve the effectiveness of carbon emissions trading.

Auctions provide several advantages over free allocation:

1. Reduced Disputes: Auctions minimize conflicts between stakeholders that can arise from free distribution, aligning with fairness and justice principles appropriate for ETSs.
2. Increased Government Revenue: By auctioning permits, governments can generate additional revenue, which can be reinvested in environmental initiatives or used to offset costs associated with the transition to a low-carbon economy.
3. Incentives for Innovation: The auction pricing mechanism encourages firms to enhance their technical capabilities and innovate towards low-emission technologies, thereby contributing to overall emissions reductions.

By considering these allocation strategies, policymakers can better design ETSs to achieve their environmental goals while promoting equity and economic efficiency.

This review indicates that many studies have arrived at similar conclusions regarding the absolute advantages and disadvantages of carbon taxes and emissions trading systems (ETSs) in terms of emissions reduction. Consequently, the current debate has shifted towards comparing the implementation of carbon taxes and ETSs, as summarized in Table 1. This shift is driven by the necessity to examine the relative benefits of each approach concerning emissions reduction, cost savings, economic efficiency, technological advancements, political acceptance, and stakeholder engagement.

Theoretical research suggests that the impacts of these two mechanisms should align when information is complete, transaction costs are negligible, and price controls are set at the intersection of the marginal costs and benefits of emissions reduction. However, in practice, information is rarely complete, and transaction costs typically exceed zero. Therefore, while both mechanisms can effectively reduce emissions, their associated costs and incentive effects logically differ.

Given the significant establishment, implementation, and administrative costs associated with ETSs, it is not surprising that carbon taxes tend to incur lower costs in these areas, making them more accessible during the initial stages of implementation. However, carbon taxes increase production costs for businesses, which can constrain profit margins and influence optimal decision-making. Firms may also pass the tax burden onto downstream producers and consumers by raising prices, potentially leading to inflation and negatively affecting overall economic conditions. Additional critiques of carbon taxes include the challenges of determining an optimal tax rate and policymakers' delays in responding to current market conditions.

Despite the benefits of carbon taxes, evidence indicates that ETSs may have a greater impact on emissions reduction and innovation incentives. Furthermore, ETSs can lower information costs and enhance the competitiveness of polluters. According to Murray et al., cap-and-trade systems are more welfare-enhancing than carbon taxes if mechanisms such as storage, banking, or borrowing of emissions rights are permitted. The ETS also clarifies overall emissions abatement goals and facilitates emissions management across international borders, making it better suited for long-term implementation. Additionally, once the total emissions allowance is established, the emissions reduction target can be more readily adjusted to align with current market conditions.

	Advantages	Disadvantages
Carbon Taxes	• Lower establishment, implementation, and administrative costs	•Higher production cost •Cause inflation and worsen the overall economic situation •Optimal tax rate is difficult to determine •Takes time for policymakers to respond to current market conditions
ETSs	•Greater emission reduction effect and incentive to innovate •Lowers information costs •Enhance the competitiveness of polluters •Cap-and-trade system is more welfare-enhancing •Better suited in the long run •More easily adjusted to current market conditions	•Larger establishment, implementation, and administrative costs •Lack price transparency

Table 1: *Comparisons between carbon taxes and ETSs.*

Nevertheless, while ETSs offer key advantages over carbon taxes, it is important to note that their establishment, implementation, and administrative costs are relatively high. Furthermore, the induced price from the carbon cap is not always transparent, which can complicate planning for firms and create uncertainty regarding overall emissions reduction costs. Even the EU ETS, one of the largest globally, has faced price volatility due to excessive quota distribution and periods of economic downturn. Therefore, it is crucial to closely monitor ETSs to ensure their effectiveness, efficiency, and sustained capacity to reduce emissions.

Abstract

The article examines socio-economic and environmental factors in the paradigm of sustainable development of the domestic economy. Some approaches to the interpretation of the concept of "sustainable development" as a scientific definition are analyzed, a triune model of sustainable development is defined, which includes economic, social and environmental aspects. The fundamental principles of sustainable development have been identified, conceptualizing the principle of reasonable consumption and a harmonious combination of man and nature. Ways and mechanisms for solving problems and achieving sustainable development goals at the national level are proposed, which involve complex and strategic changes. The role of public policy is emphasized in order to ensure coordinated activities of government bodies and local self-government towards achieving the goals of sustainable development of the domestic economy.

Keywords: sustainable development, domestic economy, ecology, social factors, resource potential

I. Introduction

One of the most significant problems facing a modern state is the problem of sustainable development, which arose as a result of the financial, economic, social and environmental crises. Global economic transformations, fluctuations in financial markets, excessive consumption of natural resources, pollution of basic ecological systems of life-supporting importance, significant reduction in the volume of agricultural land, etc., have led to catastrophic consequences and pose a real threat to national security. The need to increase economic capacity, using outdated technologies, impoverishment of production assets; high competition, low economic awareness, etc. have led to an imbalance between economic, social and environmental social systems. As scientists emphasize, it is the quantitative factor of production without an increase in quality and rational use of potential that causes depletion of natural resources, environmental pollution, worsens the quality of life of the population, and predetermines the emergence of environmental problems in most regions of the country.

If economic extensification and inefficient environmental management continue, the country may lose its own natural resource potential and have catastrophic consequences for the lives of future generations. In this regard, the priority is the problem of sustainable development of the national economy, which is aimed at integrating the economy and ecology into an integral integrity, and provides for the preservation of economic, environmental, social and natural resource potentials to meet the needs of future generations.

Currently, the issue of sustainable development is the subject of scientific analysis in the works of both foreign and domestic researchers. Various aspects of this issue are reflected in the works of S. Bobylev [1], A.A. Voloshinskaya [5], I.S. Kokorin [4], V.M. Komarov [5], N.A.

Piskulova [7], E.S. Yankovskaya [4] and many others. Despite the great contribution of scientists, the problem requires a more in-depth and systematic analysis, not only from a theoretical but also a practical point of view.

The issues of defining the conceptual foundations of sustainable development, determining theoretical approaches to the interpretation of the concept of "sustainable development" as a scientific definition, integration and differentiation of models of sustainable development, strategies and mechanisms for ensuring it are becoming relevant. The practical direction of solving the problem focuses on the need to form new strategies for the development of the national economy in accordance with the environmental paradigm; humanistic principles and values that improve the quality of life of people and restore the resource environment; initiation of the formation of an innovative, technology-oriented resource-saving economy.

II. Methods

The purpose of this article is to study socio-economic and environmental factors in the paradigm of sustainable development of the domestic economy.

The concept of sustainable development has gained great popularity in recent decades. This is due to a number of challenges that have faced society and require immediate intervention. The environment and its resources have always been the livelihood of humanity, but anthropogenic impacts are increasingly having a negative impact on nature. As a consequence, there is an imbalance in the ecosystem, an aggravation of the environmental situation, which, in turn, affects the standard of living and well-being of the population.

The concept of sustainable development is based on the search for a balance between three aspects of human life: environmental, social and economic. However, long-term and systematic human intervention predetermines global problems, the solution of which depends not on the desire of individual subjects, but on humanity as a whole.

Therefore, in the third millennium, discussions are actively underway to integrate representatives of all countries into decision-making and the formation of a common strategy to overcome pressing problems. The implementation of the concept of sustainable development is impossible without awareness of the personal role and importance of everyone. An important factor is public support and its influence on political decisions.

The theoretical analysis of the problem showed that the definition of the concept of "sustainable development" has an extensive system of interpretations. The concept of "sustainable development" was first proposed by the World Commission on Environment and Development in 1987. Since then, the category of "sustainable development" has undergone significant progressive changes and has acquired even greater relevance. The need for its comprehensive analysis is determined by the following reasons: the rate of resource consumption exceeds the rate of their restoration; the rate of consumption of updated resources exceeds the rate of their timely restoration; the scale of emissions of pollutants exceeds the ability of the environment to absorb and neutralize them.

Note that the translation of the concept of "sustainable development" is not entirely correct, since the concepts of "development" and "consistency" to a certain extent negate each other. Equilibrium defines the static state of the system, which is achieved by the influence of various oppositely directed forces that cancel each other out. Since any unbalanced state of the system is undesirable, the main task of modern research is to identify destabilizing socio-economic factors and ways to restore balance. Even in dynamic systems, states of disequilibrium alternate with their long-term states of equilibrium.

Domestic researchers of the concept of sustainable development consider it undesirable to transfer its ideology to the national economy, which requires growth, not balance. Indeed, if sustainable development is the balanced development of socio-economic and environmental systems, then economic growth based on highly industrial development will invariably be accompanied by the exploitation of natural resources, which exhaust their potential every year. With this approach, "sustainable development" is based on mutually exclusive provisions that make the problem of economic growth unresolved.

III. Results

Real positive changes are possible when the following strategic priorities of state policy are achieved, with people at the center:

– development of intellectual potential and implementation of an innovative model of economic growth in order to strengthen scientific and technological potential capable of ensuring high-tech production and creating a new strategic product - knowledge and information;

– improving the state's social policy, in particular in the area of increasing labor costs, which will contribute to the high-quality reproduction of human capital and the growth of the country's competitiveness;

– strengthening the decentralization of the economy in order to implement effective socio-economic reforms while minimizing environmental risks.

At the moment, the interpretation of the concept of "sustainable development" is ramified and covers the categories of economic growth, quality of life, environmental protection, solving environmental and humanitarian problems, rational use of resources, etc. Scientists are trying to illuminate the phenomenon of sustainable development in a structurally balanced form, taking into account its social (meeting the material and cultural needs of society), environmental (preservation of the environment) and economic (economic and technological development) components [7].

The generality of approaches gives grounds to understand sustainable development as a positive continuous process of movement that meets the needs of the population at the present time and does not jeopardize the ability of future generations to meet their own needs while preserving the environment. Attribution of the stability of these components presupposes not only the immutability of the main parameters, but also the ability to maintain and grow, reveals the ability to be in a state of dynamic equilibrium, despite the negative influence of various, both external and internal factors. Sustainable economic development in [5] is understood as such development of countries, regions, and societies, during which economic growth occurs with the possibility of restoring ecosystems to support the livelihoods of present and future generations.

Sustainable development primarily involves:

1) Improving the quality of life of people within the limits of economic activity that does not lead to the destruction of the natural mechanism for regulating the human environment and its global changes;

2) Adaptability, flexibility, efficiency of the national economy to meet global challenges; return the economic system to a dynamic and productive state;

3) The ability to quickly recover from shocks.

Sustainable development minimizes the risks of sharp fluctuations in socio-economic processes; ensures the duration of maintaining a certain level of parameters of economic systems; efficiency of production facilities.

IV. Discussion

Sustainable development should be based on two fundamental principles – anthropocentric and biospherocentric [1]. The anthropocentric principle in a broad sense refers to the idea of not only the biological survival of humanity, but, first of all, its harmonious development; search for alternative ways of relationships between man and society. Issues of morality, ethics, preservation of human freedoms, the rule of law and social justice, the priority of spiritual development are significant; scientific integration of worldview; reducing social tension; the inadmissibility of violence and aggression towards others. At the center of the anthropocentric paradigm is man, as a subject of independent, free choice and responsible action, striving for self-development and perfection in the natural environment. In this plane, the priority is the role of "Homo sapiens", as a creature of rational consumption of goods, in contrast to "Homo consumens", who thoughtlessly uses everything that nature has created to satisfy his needs.

The biosphere-centric principle means preserving the biosphere as the natural basis of life on the planet, providing conditions for its sustainability and evolutionary development. It provides for the protection of biodiversity, the absence of ecophobia, the implementation of the ecological foundations of life, etc. Biospherecentrism orients society toward the rational use of natural reserves and the achievement of a harmonious connection between man and the environment.

Summarizing conceptual approaches, it should be noted that the most comprehensive concept is one in which sustainable development is considered as a process aimed at ensuring a high quality of life through achieving balanced socio-economic and environmental development, carried out on the basis of rational use of all resource potential. In this context, the most justified is the ecological-economic concept, in which sustainable development is considered as the integration of two factors: the process of capitalization due to the production of economic goods and the process of preserving living conditions, restoration and conservation of natural resources. We should also mention the scientific works of such scientists as V.I. Danilov-Danilyan [2], M.N. Ignatieva [3], K.S. Losev [2], P.G. Oldak [6], N.F. Reimers [8], where the emphasis is on the ability of natural potential to be restored and preserved by strictly limiting the irrational use of resources and solving environmental problems. IN AND. Danilov-Danilyan, K.S. Losev [2] argue that sustainable development is the ability of a system to achieve its goals, despite the destabilizing influence of the internal and external environment through the use of socio-economic and environmental resources [2]. Moreover, scientists propose a solution to the environmental context of sustainable development through the consistent implementation of technological systems, innovative management solutions that allow increasing the efficiency of the economy and the use of natural resources while simultaneously maintaining or improving the quality of life in general.

Within the framework of the triune approach, the sustainable development of the national economy is considered as a complex integration of the following interacting factors: environmental, social and economic [4].

The economic factor, first of all, presupposes the stable, continuous and efficient functioning of the economy, the presence of a set of markets, goods and services, capital, securities, real estate, labor, etc.; competitive environment and antimonopoly legislation; sustainable GDP growth, increase in assets, capitalization of the economy; favorable investment climate; activation of production, increasing production potential, effective economic structure, etc. [4; 5; 7]. Sustainable economic development is expressed in the following indicators:

– volumes of inflow and outflow of foreign investment;
– volumes of gross fixed capital formation;
– growth of GDP per capita;
– increase in the cost of living;
– cost of fixed assets;
– level of depreciation of fixed production assets;
– increase in the average monthly salary of employees;
– creating a more competitive economy.

Thus, sustainable socio-economic development means realizing a high-efficiency, low-wage economy; its indicators should be used in long-term planning, forecasting and assessing the efficiency of national production.

The social aspect of sustainable development of the national economy shows the need to resolve issues of a humanitarian nature: overcoming unemployment, poverty; housing provision; free access to quality education and medicine; creating conditions to improve the demographic situation; care for health and well-being, increasing life expectancy; addressing issues of gender inequality, exploitation and discrimination, partnerships and peace; infrastructure development, etc. [1]. Its main indicators are: duration and quality of life; state of human health; the level of education; income level; employment level; degree of realization of human rights.

The environmental direction of sustainable development is to minimize the negative consequences of natural resource depletion and environmental pollution for subsequent generations; conservation and reproduction of the environment; climate change mitigation; conservation of marine resources; protection of terrestrial ecosystems; consumption of high-quality drinking water and food; introduction of the "green economy" [4]. This group of controlled parameters includes such indicators as the quality of the atmosphere, water, areas in a natural and modified state, forests, subject to taking into account their degree of preservation, the number of biological species under threat of extinction, etc.

Effective solution to the problems of social, economic and environmental development lies in supporting:

– efficient allocation of resources;

– stable positive economic dynamics, in accordance with the ecological system of life support;

– fair distribution of natural resources not only in current conditions, but also with a forecast for the future;

– rational use of limited natural resources;

– application of environmental resource-saving technologies;

– processing and destruction of waste;

– maintaining the sustainability of existing social and cultural systems;

– reduction of interethnic and intercultural conflicts;

– fair distribution of resources and opportunities among the entire population of the planet;

– solving problems of a humanitarian nature.

Thus, the optimal implementation of tasks and achievement of sustainable development goals at the national level involves complex and strategic changes, namely:

1) Gradual restoration of ecosystems to a level that ensures the sustainability of the natural environment to meet vital needs;

2) Effective self-organization of social, environmental and economic systems;

3) Biosphere compatibility in a situation of reduced level of anthropogenic pressure on nature;

4) Economic efficiency in conditions of acceptable environmental organization of economic activity.

To do this, it is necessary to make changes to the processes of planning, modernization and monitoring of national economic development indicators, to ensure government funding for sustainable development, and to improve the system for implementing regulatory and evaluation mechanisms. The implementation of the concept of sustainable development can only be achieved if the efforts of the entire world community are united, but each state must begin to move towards this goal independently.

The concept of sustainable development can be considered the dominant development strategy for society in the third millennium, since it depicts ways to solve global problems of humanity that relate to economic, social and environmental components.

In its evolution, the concept changed with a change in the main emphasis on its interpretation, the interaction of its main components, and the understanding of the interaction between man and the environment improved. However, the most important goal that society must achieve is that it cannot develop beyond the capabilities of the ecosystem, because such behavior threatens the well-being of existing and future generations. Since achieving this goal is global in nature, it requires the involvement of a wide range of stakeholders.

Sustainable development of the national economy presupposes the formation of a balanced connection in the "man-nature" system, functioning under the condition of achieving a high standard of living of the population, an effective, prosperous economy and conserved resources. Achieving the goal of sustainable development of the national economy is complex and depends on a large number of mechanisms, conditions and factors. The issue of government regulation is of fundamental importance here. Concepts and strategies for sustainable development of the Russian Federation must be supported by relevant regulatory documents, legislative acts and programs for the socio-economic development of the country, in order to ensure coordinated activities of state authorities and local governments towards achieving the goals of sustainable development of the domestic economy.

EXTREME DESIGN STORMS FOR FLOATING NUCLEAR POWER PLANT PROJECTS

Izmail Kantarzhi
•
Dept. of Hydraulics and Hydraulic Structures
of National Research Moscow State Civil Engineering University, RUSSIA
kantardgi@yandex.ru

Abstract

The overflow of waves over the crest of the protective structures of the port of refuge of a floating nuclear power plant creates a threat of accident risks. The design of hydraulic structures of floating nuclear power plants requires the determination of design storms with a frequency of up to 1 time in 10000 years: overflows, force loads, etc. This is an unconventional task for marine hydraulic engineering. The methodology and results are shown in relation to the design of the PEVEK floating nuclear power plant (FNPP) port in the Chaun Bay of the East Siberian Sea. To calculate the probability of waves of rare recurrence up to 1 time in 10000 years, the method of annual maxima applied to storms for the thirty-year period 1991–2021 is used, the distribution of peak values in which is approximated using GEV (in the form of a Weibull distribution). Maps of possible large wind waves of recurrence once every 5, 10, 25, 50, 100, 1000, 10000 years on the approach to the port were obtained. To calculate the characteristics of waves in the East Siberian and Chukchi Seas, up to the deep-water boundary of the FNPP water area, the SWAN model was used, the wind fields for the calculation of which are based on the data of the NCEP/NCAR reanalysis of wind fields in the period from 1991 to 2021. To construct extreme wave fields of various recurrence, the maximum values of wave heights for each year were selected at 993 points of the nodes of the rectangular grid with a cell size of 22 m for the FNPP water area. Thus, a numerical model of wave generation and transformation has been developed based on the adaptation of the SWAN model on an unstructured grid covering the East Siberian Sea design area. The mesh cells thicken towards the FNPP water area, decreasing in this region to a characteristic size, about 2.5 m. To calculate extreme wind-wave fields over a 30-year period, 37 storm scenarios were selected. Those periods of extreme winds from July to September were selected, in which the average wind speed in the area of the Chaunskaya Bay exceeded 10 m/s. Wave fields were obtained for all these storms in the FNPP region, the statistical processing of which made it possible to obtain wave fields of significant (13% in the storm system) waves with a frequency of 5, 10, 25, 50, 100, 1000 and 10000 years. At about 300 m from the shore, the height of significant waves of this frequency will vary in the range from 1.3 m to 3.4 m. Wave heights of 50%, 5%, 1%, 0.1% of the probability in the storm system in the same area were calculated. For waves of 1% probability with recurrence once in a hundred years, the height of the waves reaches 3.1 m, once in 1000 years - 4 m, once in 10000 years - 4.5 m.

Keywords: storm, nuclear power plant, overflow, accident risks

I. Introduction

The site for the construction of onshore and hydraulic structures for the operation of the floating nuclear power plant based on the floating power unit of project 20870, is located one kilometer northeast of Pevek.

In the available materials of hydrometeorological surveys, it is noted that in the water area of the port of Pevek, in the area of the berths, with the winds of the north-eastern quarter, the maximum wave height can be 1.8 m.

The purpose of the research is to ensure the selection of a rational layout and designs of hydraulic structures designed for a floating nuclear power plant in Pevek, Chukotka region.

Figure 1: *Overview map of the East Siberian Sea and the Chukchi Sea with the location of the city of Pevek*

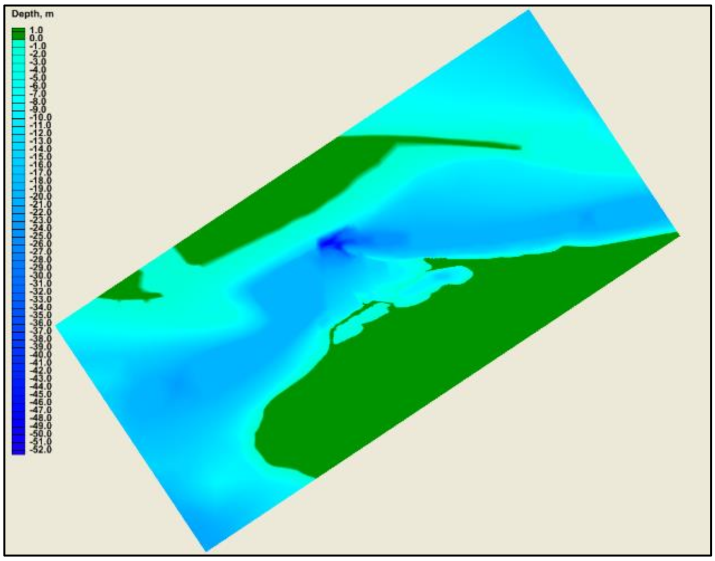

Figure 2: *Distribution of depths in the Pevek Strait, constructed from a digital map supplemented by digitization of the depth map*

In accordance with the work plan, the research includes the following works:

1. Analysis, evaluation and generalization of source materials, including:
   - fund materials and observational data obtained as a result of engineering surveys;
   - factors that cause hydrodynamic and thermohaline processes;
   - typification of ice conditions of the Chaunskaya Bay.
2. Analysis of options for the layout of hydraulic structures with recommendations for choosing the final option for the location of the station.
3. Assessments of lithodynamic processes in the area of the station location to justify dredging operations.
4. Mathematical modelling of lithodynamic processes in the area of the station location to substantiate dredging operations.

5. Modeling of wave, current and ice fields (including under conditions of a combination of unfavorable hydrodynamic factors of rare recurrence - waves, currents, fluctuations in sea level and ice) to determine the layout of hydraulic structures that provide minimum loads from waves, currents and ice, namely:

- mathematical modelling and calculation of wave and wind fields in the water area, including the places of potential location of the hydroelectric station (calculations should be carried out using modern methods for the provision of loads once in 10000 years, taking into account the change in sea level according to global estimates due to climate change, as well as tidal and surge currents);
- mathematical modelling in 2D format and calculation of current fields in the water area, including the locations of the potential location of the station gas station (calculations should be carried out using modern methods for the provision of loads once in 10000 years, taking into account the change in sea level according to global estimates due to climate change, as well as tidal and surge currents);
- Mathematical modelling and calculation of the dynamics of ice fields in the water area under storm conditions, for the areas of potential location of the gas station. The calculation should be carried out taking into account the typification of possible ice impacts on hydraulic structures in the Chaunskaya Bay, including loads from a moving hummocky ice field, in particular an "ice storm", from a continuous ice field when it expands, loads from ice jammers.

Next, we will consider the method adopted in this work for determining extreme design waves with a probability of up to 1 time in 10000 years.

II. Methods

The following methods and models were used for numerical modeling of waves in the studied water area. COASTOX-MORHO is a software system designed to solve two-dimensional equations of wave propagation, current formation, sediment transport, bottom and shore erosion based on high-performance numerical algorithms. COASTOX uses finite volume methods on unstructured grids, parallelization algorithms for calculations on multiprocessor and/or multi-core systems. The system can be used for calculations on personal computers and multiprocessor clusters, additional modules of the system allow you to calculate the transfer of pollutants (toxic elements and radionuclides) in rivers and the coastal zone of the sea.

In the last decades, the spectral model of the Technical University of Delft (Denmark) SWAN [1], distributed in open code, has become a generally accepted tool in the world practice of coastal engineering for calculating the transformation of wind waves from deep water to the coastal zone.

The HWAVE-S model [2] is a semi-spectral version of the HWAVE monochromatic model. Models of this class are based on the assumption that irregular wind waves are represented as a linear superposition of an infinite number of harmonic waves propagating independently of each other. Such models also include the REF/DIF-S [3] and ARTEMIS models [4]. HWAVE-S allows you to simulate the refraction-diffraction transformation of the wind wave spectrum near structures.

In the implementation of projects for scientific and technical support of engineering projects, both the above models and open-source models are used - the WRF meteorological model, the VERY oceanographic model, the Wave Watch spectral model of the formation and transformation of wind wave fields.

According to the existing technology of mathematical modeling, in the tasks of marine hydraulic engineering and hydraulics (design of hydraulic structures of ports and shore protection structures), the following main stages are distinguished:

1. Calculation of climatic characteristics of wind waves at specified points on the approach to the object under study (port, coastal area) on the basis of spectral models of wind waves from wind fields over the sea for a long-term (30 - 50 years) period (using meteorological element fields from the reanalysis of NCEP\NCAR or ERA-40 meteorological fields, with their possible downscaling (dynamic interpolation) using numerical weather forecast models.

2. Calculation of the wave regime of a coastal zone or enclosed sea area based on mild slope equations (in elliptical, parabolic or hyperbolic approximation) or nonlinear dispersion equations of the Boussinesque type.

3. Calculation of coastal currents generated by the combined influence of wind, waves and sea tides, taking into account the possible reverse influence of currents on the transformation of waves.

4. Calculation of sediment transport in the coastal zone and reformation of the bottom and banks.

In modern practice, three methods of statistical analysis of extreme values of oceanographic (hydrometeorological) parameters are used, based on approaches developed in the modern theory of statistics of extreme values [5-9]. These approaches are considered using the example of extreme wind wave statistics, taking into account that the same approaches are applicable to statistics of extreme values of current velocities and other hydrometeorological characteristics.

III. Results

I. Technologies for Mathematical Modeling of Wind Wave Fields in the Water Area of the FNPP Location

To calculate the characteristics of waves in the East Siberian and Chukchi Seas, up to the deep-water boundary of the FNPP water area, the following will be used: the SWAN model, for the calculation of which wind fields are used, the data of the NCEP/NCAR reanalysis of wind fields in the period from 1991 to 2021 are used, with the involvement of data refined from satellite observations and wave measurements in the region for adjustments.

NCEP/NCAR reanalysis is a project of the National Centers for Environmental Prediction (NCEP) of the US Hydrometeorological Service (NOAA) and the US National Center for Atmospheric Research (NCAR) to restore meteorological element fields over the past 40 years around the globe, using instrumental observations and modeling results [10], http://www.cpc.ncep.noaa.gov/products/wesley/reanalysis.html, http://www.esrl.noaa.gov/psd/data/reanalysis/reanalysis.shtml).

As the main source of meteorological data after 1999, the final analysis (http://dss.ucar.edu/datasets/ds083.2/) meteorological fields were used, which were used to initialize global weather forecast models of the US National Center for Environmental Forecasting (NCEP). These fields are calculated by the Global Data Assimilation System (GDAS, http://www.emc.ncep.noaa.gov/gmb/gdas/).

An important circumstance in favor of the choice of these data was their relatively high resolution (1 degree compared to the resolution of 2.5 degrees of the NCEP and ERA-40 reanalysis data) and the fact that, in addition to standard observations, these data assimilate a variety of satellite measurements, including propulsion wind measurements made using the SSM/I microwave radiometer [11], as well as other measurements. produced from NOAA satellites (using AMSU, HIRS instruments) and GOES geostationary satellites. These data were not used in the calculations of the NCEP R2 and R1 re-analyses, so it is preferable to use the data of the final analysis. Data from the final analysis have been available since 1998. For earlier periods (from 1990), NCEP reanalysis data 2 [12] were used, which cover the entire required period.

In addition, downscaling (dynamic interpolation) of wind data from NCEP reanalysis for several of the strongest storms for the FNPP region was carried out by the WRF meteorological regional model, with a grid resolution of up to 1*1 km to assess the significance of such downscaling for the accuracy of calculating wave characteristics on the approach to the FNPP water area. In the event that downscaling shows a significant effect of grid thickening on the calculation accuracy for wind speed, such calculations will be performed for all selected storms for the calculation period.

The results of the SWAN model calculations will be used as boundary conditions for the HWAVE–S model, a half-spectral model that, based on the equations of gentle slopes, allows you to successfully describe the diffraction effects and the effects of wave reflection from the protective structures, which is especially important for the area adjacent to the FNPP barrier breakwaters.

Taking into account the ROT methodology, at least 30 of the strongest storms will be selected over the specified 20-year period and the distribution of peak values in the resulting sample is approximated using GEV and GPD distributions. At the same time, as an estimated value of wave height for each control point near structures, the highest of the probability values of 1 time in 10000 years, calculated by these two methods, will be recommended. In addition, similar calculations will be made for the 21st century maximum possible storm scenarios, taking into account adjustments for changes in sea level and wind speed, in line with existing studies of climate global change.

Such a methodology is adopted on the basis that the requirements for the design characteristics of extreme wave parameters once every 10000 years do not mean that it is necessary to consider not the period of 10000 years of continuous operation of the floating nuclear power plant, but only the risks of the implementation of such an extreme phenomenon as storm waves of probability once every 10000 years during the 21st century, which justifies the use of climate change scenarios in the 21st century to calculate such availability.

II. Computational Grids of the Wind Wave Model in the Water Area of the FNPP Location

Wind field calculations were carried out on an unstructured grid covering the East Siberian Sea from 150° to 178° E. longitude and to the north to 80° S. latitude (Fig. 3). The number of computational mesh nodes is 94143, the number of elements is 185910. The linear size of the elements in the FNPP water area is about 2.5 m.

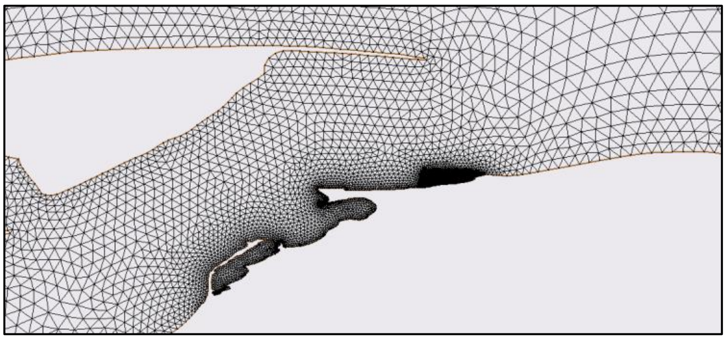

Figure 3: *A fragment of the grid for calculating wind waves in Pevek area.*

To construct extreme wave fields of various recurrence, the maximum values of wave heights for each year were selected at 993 points of the nodes of the rectangular grid with a cell size of 22 m for the FNPP water area. For each point of the grid, Weibull distribution parameters were obtained, from which the values of the heights of waves of rare repeatability were calculated. Maps of possible large wind waves of recurrence once in 10000 years are given in Fig. 4 (the map is built in the metric coordinate system). The dots show the location of the proposed wave protection moles of the floating nuclear power plant.

For greater clarity of the values of the heights of waves of rare recurrence, the values at the cross-section points (Fig. 5) located at a distance of about 300 m from the shoreline on the isobath were interpolated from the above fields.

Graphs of the heights of significant (13% certainty) waves along this section for waves of different recurrence (YRP - years return period) are presented in Fig. 6.

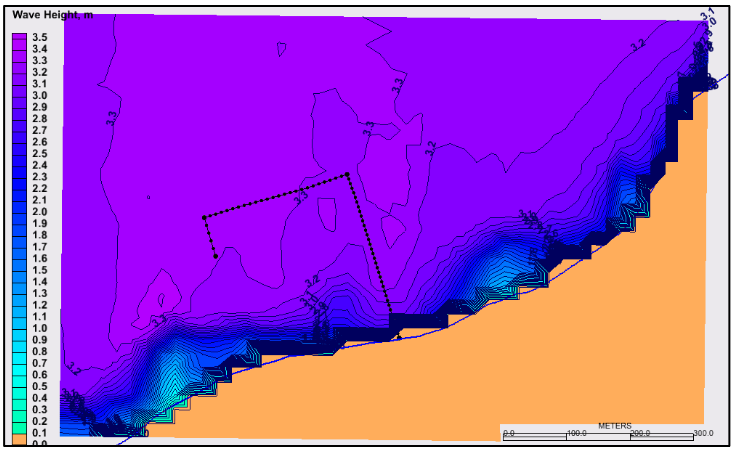

Figure 4: *Heights of significant waves, possible once in 10000 years*

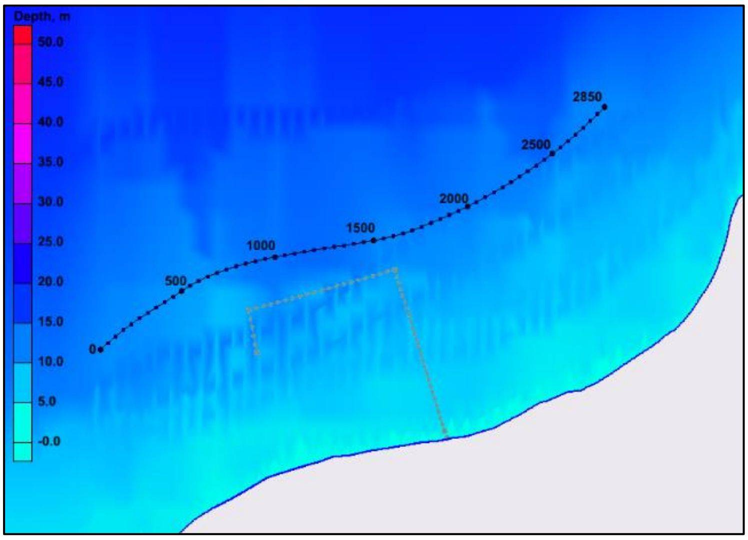

Figure 5: *Line of issuing points, 300 m from the shoreline*

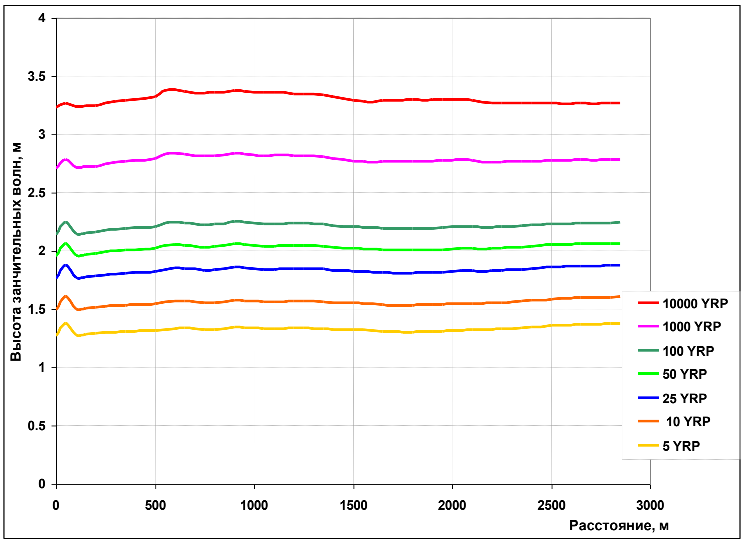

Figure 6: *Heights of significant waves of rare repeatability along a cross-section*

Wave heights of 50%, 5%, 1%, 0.1% of probability (availability in the storm system) were calculated according to Glukhovsky's formula [13] for waves of rare recurrence:

$$\frac{h}{\bar{h}} = \left[-\frac{4}{\pi}(1 + 0{,}4h^*)\ln F_h \right]^{\frac{1-h^*}{2}} \qquad (1)$$

where h is the height of the waves of a given position, $h^* = \bar{h}/D$, F_h is the security of the wave height (fractions of one), D is the actual depth of the place (m).

The average wave height ($\bar{h}$) was calculated iteratively using formula (1) from the height of significant or 13% of the waves.

IV. Discussion

To calculate the availability of waves of rare recurrence up to 1 time in 10000 years, the POT method was used, applied to storms for the twenty-year period 2000 - 2021, the distribution of peak values in which is approximated by GEV and GPD distributions with the selection of the highest values from those calculated by these two methods. The generally accepted methodology for calculating oceanographic parameters in the context of climate change is based on the use of projections - scenarios of global meteorological processes in the 21st century, recommended by the UN International Commission on Climate Change (IPCC), followed by the calculation of global oceanological models of sea level change. The results of such calculations regarding the global change in wind fields and sea level were used to adjust the calculations of wave heights, current velocities and erosion intensity in the FNPP area.

For all types of modeling, initial data files were prepared, including bathymetry of the site with grids thickening to the construction site. This made it possible to simulate the fields of external factors in the design area on grids with dimensions up to 2.50 m in the plan. In addition, the necessary hydrometeorological information was collected as initial information for modeling. Survey materials, information from international hydrometeorological databases available on the Internet, as well as direct requests to Roshydromet organizations were used as sources of information. Thus, the models used are "tuned" for the conditions of the FNPP design site and can be used in the future.

Modeling was carried out for specific conditions, the modeling results were compared with the available observational data and measurements of the relevant parameters: current velocity, ice thickness. Comparisons show that the models can be successfully used to determine the design characteristics of the external load on the plant's hydraulic structures.

Wind field analysis in the region, conducted using the wind field from 2000 to 2021 from NCEP/NCAR Reanalysis-2. It should be noted that the atmospheric pressure obtained from the results of Reanalysis-2 at the installation point of the weather station, at the FNPP onshore site, in July-August 2021, is in good agreement with the measurement data. The dynamics of the change in wind speed at this point corresponds to the measured one, with a slight excess of the speed in the peaks of the storm wind from Reanalysis-2 over the measurement data in the specified period.

A numerical model of wave generation and transformation has been developed based on the adaptation of the SWAN model on an unstructured grid covering the East Siberian Sea from 150° to 178° E. longitude and to the north to 80° S. Latitude. The grid cells condense to the FNPP water area, decreasing in this region to a characteristic size: about 2.5 m. 37 storm scenarios were selected to calculate extreme wind-wave fields for the 30-year period from 1991 to 2021. Those periods of extreme winds from July to September were selected, in which the average wind speed in the area of the Chaun Bay exceeded 10 m/s. Wave fields were obtained for all these storms in the FNPP region, the statistical processing of which made it possible to obtain wave fields of significant (13% in the storm system) waves with a frequency of 5, 10, 25, 50, 100, 1000 and 10000 years. At a distance of about 300 m from the shore, the height of significant waves of this frequency will vary in the range from 1.3 m to 3.4 m. Wave heights of 50%, 5%, 1%, 0.1% of the probability in the storm system in the same area were calculated. For waves of 1% probability with a recurrence of once in a hundred years, the height of the waves reaches 3.1 m, once in 1000 years - 4 m, once in 10000 years - 4.5 m. At the same time, at the 10 m isobath in the FNPP water area, the maximum height of significant (13%) waves did not exceed 2 m over the analyzed 30-year period.

The periods of waves with recurrence from 5 to 100 years, with the probability in the storm system from 50% to 0.1% in the water area of the floating nuclear power plant, vary in the range of 4.4 - 6.5 seconds, and for waves with a recurrence of once every 10000 years, the periods reach 7.8 seconds. It should be noted that the simulation results for waves with a recurrence of once in a hundred years do not contradict the data given in the Terms of Reference for Design Surveys, according to which "on the approach to the port of Pevek" 1% of the wave has a height in the range of 3 m - 5 m and a period of 6.9 seconds.

The wave height fields in the design area are quite heterogeneous, it is advisable to take this fact into account when choosing the location of the berth. The height of waves in a storm with a recurrence of 1 time in 10000 years with a probability of 1% is about 5 m.

To calculate the load from waves on the hydraulic structures of the station, it is recommended to take at the approach to the structure, at a water depth of 10 m, the height of waves in a regime storm with a recurrence of once every 10000 years, a probability in the storm system of 1% - 4.6 m, a probability of 0.1% - 5.4 m, an average wave period of 6.91 s, the direction of the waves - N-SW. If necessary, the period of waves of 1% probability – 7.81 s, and the period of waves of 0.1% – 7.94 s, with a recurrence of 1 time in 10,000 years, can be used for calculations.

Similar wave modes are recommended to be adopted in physical modeling of the stability of hydraulic structures to the wave load.

Abstract

The article is devoted to the role and importance of small business in the modern world and its contribution to the development of green economy. It is noted that serious attention in economically developed countries is paid to the development of small enterprises as one of the most important sectors of the economy, which plays an important role in the socio-economic development of the country. The economic advantages of small business are considered, which include: lower cost in creating jobs; high internal mobility in changing demand using local resources inefficient for large-scale production; high profitability of activities in "narrow" segments of the market, small capital in organizing business, etc. It is determined that for all countries the financial infrastructure of small business is the most important component of the economic system. The processes of revival and development of entrepreneurship in Russia with the beginning of market reforms of the late XX century have been studied. It is established that the sustainable development of business structures, including those belonging to small business, is impossible without taking into account the trends of "green" economy, since the satisfaction of consumers today should not infringe on the interests and needs of future generations.

Keywords: entrepreneurship, middle class, small business, market transformation, post-industrial era, green economy

I. Introduction

Entrepreneurial activity in the modern economy represents the main source of increasing the material well-being of the population. In all countries, the financial infrastructure of small and medium-sized businesses is accepted to be considered as the most important part of the national economy. [1] In this regard, the authorities of many states in every possible way promote the development of small business enterprises, which, in turn, leads to employment growth. In the process of managing the development of territories, the activity of entrepreneurial structures is currently taken into account. At the same time, an important factor at the local level for municipalities is the activity of entrepreneurial structures classified as small businesses.

II. Methods

Within the framework of the Second International Scientific and Practical Conference on the problems of financing and crediting of the small and medium business sector in Russia, the necessity of accelerating the process of creating a domestic socially oriented financial structure of small and medium-sized entrepreneurship in the country was determined.

Toreev V.B. and Voronovskaya O.E. believe that the domestic banking sector is more focused on servicing large businesses, thus significantly increasing the costs of lending to small companies and leading to an increase in interest rates on loans.

Aleksandrov A.L. and others note that the formation of market relations in Russia has led to significant changes in the standard of living of the Russian population and set new tasks for state institutions in the field of economic welfare.

Ivanovskaya M.A. and Glukhova Z.V. in their work consider the processes of the impact of scientific and technological progress, globalization and internationalization processes on the environment, the state and exploitation of natural resources to ensure the life activity of modern society.

Basareva V.G. reveals the relationship between the level of development of small enterprises and the level of decline in industrial production. According to the author, the confirmation of the hypothesis of mutual influence of these processes in the period of transformational decline helps to adjust selective measures of state support of small business and increase their effectiveness in the crisis.

Vanyukov D.A., studying the history of the USSR of the period of developed socialism, called the era of "stagnation", believes that despite this name, this time was as significant for the country as Stalin's construction and Gorbachev's perestroika.

Muravyev A.I. and others in their work consider the processes of formation, development and prospects of entrepreneurship in Russia and abroad, investigate the most important aspects of economic management, such as financial and personnel management, securities transactions, innovation activity, marketing, etc.

Schumpeter E.A. pays great attention to the development of the technique of economic analysis, also studying the historical context of this development, the evolution of other social sciences and social thought in general, the formation of economists as a scientific community.

One of the important features of small business in developed countries in modern conditions, according to K.V. Pavlov and I.G. Andreeva, is its integration into the production networks of large industrial structures.

As noted by Nikulina O.V., in the conditions of modernization of the national economy, the purposeful formation of an effective mechanism for managing the innovative development of industrial enterprises using the advantages of the implementation of cluster strategies for Russia can ensure the transition to a qualitatively new level of economic development and the status of a world technological leader in the context of globalization.

A.A. Pakina and V.A. Gorbanev believe that the transition of world development to the post-industrial phase is accompanied by the aggravation of global problems, the solution of which is possible within the framework of green economy, the basic principles of which meet the modern concepts of balanced development and largely coincide with the provisions of the domestic concept of rational nature management.

According to Volkova I.A., Galynchik T.A., small and medium-sized businesses are more susceptible to greening, thus can affect the change of the environmental situation in the region, optimize the process of using natural resources.

When conducting this scientific research, such scientific methods as the method of comparative analysis, statistical analysis, comparative analysis, functional analysis, positive and normative analysis were applied. The scientific research was conducted in accordance with the problem-chronological principle, the principles of systematicity and scientific objectivity.

III. Results

Effective socio-economic development of many countries of the world is determined by the development of small and medium-sized enterprises. Small and medium-sized enterprises carry out their activities as follows independently and in integration with backbone companies. This activity is ensured by a well-developed, historically established and formed for solving the tasks of accelerated economic development by the system of financing and crediting of small and medium-sized enterprises. In the Document on the Policy on Small Business in the European

Union, published in 1995, it was noted that targeted assistance for small companies is the most profitable way to create new jobs in the country [2].

Small business reduces the level of social tension in society and strengthens the processes of democratization of market relations, contributing to the formation of the middle class, raising the standard of living of its citizens, preventing the development of the shadow economy, which is its most important social function. The presence and growth of the middle class in the country confirms the effectiveness of reforms and can be considered an indicator of the strength of the entire system of socio-economic and political institutions, while its absence indicates the opposite. Even Aristotle in the ancient centuries noted the importance of the "middle class" as a factor of society stabilization [3].

It is worth noting that the first to use the concept of "entrepreneurship" in the 18th century was the English banker and economist Richard Cantillon, who implied under this concept an economic activity, as a result of which the correspondence of commodity supply and demand in conditions of risk is ensured, and an entrepreneur is a person who turns the means of production acquired in the market into capital. The result of the functioning of capital is the creation of products that are sold on the market at a higher price than its cost, and since its market price is not known in advance, entrepreneurial activity is a risk. In the Middle Ages, as well as throughout the XVII-XIX centuries in the definition of these concepts was dominated by profit through a rational combination of factors of production, and risk was presented as inherent in business, but since the XX century, especially it can be seen in the works of A.I. Schumpeter, the innovative nature of entrepreneurial activity becomes a dominant feature [4].

IV. Discussion

One of the important conditions in the development of entrepreneurship is motivation and if in the XIX century there was a predominance of motives of economic nature, then for the modern period prevail become socio-psychological, consisting in the fact that entrepreneurial income can often be no higher than the salary of a highly skilled worker. In modern economic science there are two main approaches as to who is an entrepreneur. Some economists consider any owner of the means of production to be an entrepreneur, which is acceptable for small and part of medium-sized businesses, while others consider a manager in this capacity, which is true for large businesses. It should be noted that the scientific position of the mid-1970s regarding the continuity of the process of concentration of ownership of capital, increasing the size of enterprises and firms in practice has not been sufficiently confirmed. In fact, in industrialized countries there was a growth in the number of small businesses, and more jobs in the country, attributable to these structures, thus highlighting small business as the most important source of employment and labor income for the population. It was also noted by scientists from different countries that the growth of employment in small companies was determined by the situation in the sector of large enterprises. According to their opinion, the labor force released by large enterprises was injected into small businesses. Large companies in years of economic instability could drastically reduce the number of their employees, while for small structures this period was more favorable. Significant increase in the number of small businesses, in accordance with the Birmingham model of development in England small businesses, was the result of regional and national industrial decline and corporate restructuring [5].

The formation of entrepreneurship in developed countries occurs on the basis of cooperation between large and small companies, when the activities of large firms are oriented not to suppress small companies, but to realize mutually beneficial cooperation with them. Thus, the structures of large and small businesses try to mutually complement each other, especially it can be observed in the sphere of specialization of individual productions and innovative developments [6]. If the activities of large companies are aimed at satisfying mass and rather homogeneous demand, small businesses operate in small market segments, distinguished by a limited range of production. Market niches are markets, for the most part, of high-tech finished products, the existence of which is determined by the peculiarities of the development of modern economy and international trade relations, when the demand in a particular market due to its small capacity can not be satisfied by large businesses or there is no possibility to cover the entire market with production. [6] An ancient Chinese proverb stating that a small boat, unlike a large ship, is easier to maneuver is appropriate here.

In the period of post-industrial development, the needs of small business structures regarding the introduction of innovations, research and marketing are increasing. There is a need to produce small batches of different goods characterized by high added value. Such spheres of economy as sports, recreation, entertainment, health care, fruit production and flower breeding, including traditional sectors of the economic system, have great opportunities in this direction. Almost all countries have actively developed small business, which takes into account modern features of the world economy functioning in full: innovation imperative, autonomization of the employee and his creative interaction with the employer, high rates of implementation of business ideas in the activities carried out.

Thus, according to English economist G. Bennock, it was small business in the XX century that created more than half of such significant inventions as electronic tubes for TV sets, air-conditioning unit, electrostatic copying machine, ballpoint pen, mixer, toaster, vacuum cleaner, transistor and many others. In developed countries, innovation policies focus on small and medium-sized innovative enterprises. In Japan, for example, the share of small innovative companies in the economy reached 99% of the total number of enterprises and they produced up to 52% of the country's GDP. [7] In the U.S., when conducting the program "Innovation activity of small enterprises" a good result was obtained, when the state for 20 years for every dollar spent was able to get eight, at the same time under this program, funding could receive only those companies that implemented the scientific results of universities [7].

The social functions of small business, in addition to those already discussed, are also assistance in attracting additional labor resources, almost unclaimed by other groups of employers, such as pensioners, minors, mothers with many children, and people with limited working capacity. This circumstance is also important due to the fact that the share of these categories of people in the total Russian population is constantly increasing. Small companies employing hired labor are flexibly adapted to use the labor of the elderly, home-based workers, and young students.

Increasing the employment rate and, as a result, reducing the unemployment rate, improving people's living standards and reducing the number of poor people through inclusion in the small business sector contributes to the realization of other social functions of small business such as counteracting negative social phenomena by reducing crime, drug addiction, alcoholism; providing an opportunity for self-realization of people who have a special initiative and entrepreneurial spirit.

Among the economic advantages that contribute to the development of small business structures, one can include lower cost of job creation, high internal mobility in changing demand based on the use of local resources inefficient for large-scale production, high profitability of activities in "narrow" segments of the market, focused on a specific and limited range of consumers, ease of organization, small capital in the organization of production activities, etc.

Entrepreneurship requires not only solid economic knowledge, determination, business acumen, willingness to take risks, but also the presence of extraordinary thinking, the ability to create and these circumstances determine the representation of entrepreneurship as a separate factor of production.

The condition for the formation of market structures in Russia was the revival and development of entrepreneurship, which was a prohibited activity during the Soviet Union. Although the monopoly on entrepreneurial activity during the Soviet era belonged to the state, the unofficial private entrepreneurial sector occupied a significant place in the Soviet economy, especially in the Baltic republics. Thus, according to the American economist V. Trail, by the early 1980s the shadow sector of the Russian economy accounted for up to 30% of the gross national product of the state, and the excess of income of "shadow workers" from the official statistical level reached 8-10 times, up to 15 million people were fully or partially involved in this sphere. [8]

In the late 80s of the XX century in the country there is a revival of entrepreneurial activity, which was indicated by the adoption of the USSR law "On individual labor activity" of November 19, 1986 and the law "On cooperation in the USSR" of May 26, 1988. Later on, other laws were adopted: the law of the RSFSR "On Enterprises and Entrepreneurial Activity" of December 25, 1990; the law of the USSR of April 2, 1991 "On the General Principles of Entrepreneurship of Citizens in the USSR". In 1987 cooperatives began to appear and actively develop, the number of which for 1989 increased 2.6 times, amounting to more than 102 thousand on January 1, 1990 and 132 thousand - by January 1, 1991 [9].

Government support played an important role in the development of small business. Thus, on June 14, 1995 the country adopted the Federal Law "On State Support of Small Business of the Russian Federation", which referred to the subjects of small business and individuals engaged in entrepreneurship without forming a legal entity. However, there were difficulties associated with the fact that these forms of entrepreneurship in state planning were not taken into account, thereby hampering the flow of resources into the area under consideration, which negatively affected its competitiveness, delayed the registration of enterprises, especially joint ventures, due to bureaucratic delays, which could sometimes take more than 1 year to overcome. Imperfect legislation in the field of private entrepreneurship also put obstacles in the way of the development of entrepreneurial structures in the country, resulting in the fact that the share of private companies in the total volume of production in these years amounted to only a few percent.

Thus, as of 1998, 6% of Russians over the age of 15 were successfully engaged in entrepreneurial activity. [10] Also among the Russian regions in terms of the level of development of small business structures there was noted quite high differentiation, the index of which was up to 10 times. According to the data for 1999, the Central Federal District accounted for the largest share of small business entities - 34.2%, including Moscow - 19.8%, and the smallest share - the Far Eastern Federal District - 4.3%. [11]

It is worth noting that the state support provided to small and medium-sized businesses, carried out in Russia in the form of preferential taxation, reduced contributions to extra-budgetary funds, providing easier access to cheap sources, accelerated depreciation contributed to the increase in the number of small and medium-sized companies on the basis of unbundling of large firms and separation of legally more profitable units from them under the guise of small and medium-sized businesses. As a result, the tax base and tax revenues were reduced, as this increase in the number of SMEs was based on a decrease in the number of unbundled parent companies of large businesses. In the late fifties and early sixties of the XX century, similar processes were observed in the U.S. economy in the conditions of substantial state support to small business. [12] Therefore, in order to provide state support not to subdivisions of large companies, but to those who really need it, they began to talk about the need to strengthen the targeting of benefits to small and medium-sized businesses.

In general, it should be noted that market reforms for Russia and Eastern European countries were implemented with huge losses due to the policy of "Washington Consensus", while such countries as post-war Germany and Japan, today's China and Vietnam on the basis of stimulating their comparative competitive advantages or in modern times, gradually liberalizing the economy, focusing on macroeconomic stability and competitiveness of their producers, were able to achieve high results at the expense of insignificant amount of losses.

In the Russian economy, small business as a subject has existed for several decades, playing an increasingly important role in the socio-economic development of the country. Small business in the country continues to develop, acquiring more and more features typical of a civilized form of the market, but, despite tangible state support, in recent years it has lagged behind its Western counterparts in terms of the level of its development, which makes it impossible to present it as the main "generator" of the middle class.

Sustainable business development in modern conditions is impossible without taking into account the trends of "green" economy, since meeting the needs of modern society should not harm the interests and needs of future generations. The changes that are taking place within the world and national economies have led to the need to revise many of the foundations of the theory of economic science, in which there are new types, methods, techniques and models, one of which is the green economy. [13] More and more countries of the world, transnational corporations, entrepreneurs and ordinary citizens choose the path of responsible attitude to resources and determine their actions in accordance with the global environmental agenda.

In Russia, not only large companies have taken the orientation on "greening" business, but also among small businesses there are more and more "green" projects. The reform of waste collection and disposal, the implementation of which began on January 1, 2019, has brought environmental problems to a new level of required solutions on the part of the state, business and technology. The concept of green economy development is presented as a new trajectory of harmonious (clean) development of society as an alternative model to the existing (raw material) economy, interconnecting further economic development depending on the state of the environment. According to the UNEP conclusion, the main areas of green economy are such sectors of economy as agriculture and fisheries, water and forestry, industry (primarily energy), construction, domestic and industrial waste management, transportation, tourism [14].

Green technologies lead to the improvement of the environment due to the reduction of negative impact on it, ensure the improvement of public health, contribute to the achievement of safety, resource efficiency and environmental friendliness of the functional activities of small companies. Small business management in the conditions of ecological transformation occurs with the help of a certain set of interrelated resource and incentive effects. The transition to green technologies leads to a synergetic effect, resolving the contradictions between the main goal of organizations' activities - profit and their interest in caring for the environment, saving and reproduction of natural resources, preserving public health. It is also important to take into account regional specifics in the process of small business development as a necessary aspect, both in environmental projects and in the process of formation of programs to improve the efficiency of small business structures [15].

In all countries of the world it is possible to observe the regulation of entrepreneurial activity by the state. In some countries, for example, Italy, the Netherlands and Russia, the normative base of entrepreneurial activity is included in the civil law, in other countries - France, Germany, Portugal, these norms are considered as an independent branch, there are countries where these norms are codified, i.e. Commercial Codes operate along with the Civil Code. But common for all these states is the allocation of entrepreneurial activity as a sphere of regulation, contributing to a better consideration of the peculiarities of this activity and, consequently, its development.

In the Russian economy there are many obstacles to the development of small business structures. The number of small enterprises in the country is not increasing at a very high rate, and the contribution of small business to the production of Russian GDP is not so significant. To overcome the existing negative trends in this area, it is necessary to develop and apply an effective system of state support of small business structures. The gradual transition of the country to a qualitatively new state, with the predominance of the "new economy", should be accompanied, first of all, by an active state policy, pursuing the goal of using the main and most promising potential for the development of scientific knowledge. What place Russia will occupy in the rapidly changing and contradictory world depends on the extent to which it will be possible to use this potential. The crisis and its consequences provide a unique opportunity to radically improve the fundamental legislative framework.

THE CONCEPT OF SUSTAINABLE DEVELOPMENT AND FINANCIAL MECHANISMS: GREEN HYDROGEN AND BLUE BONDS

natalia229@mail.ru

Abstract

The UN concept of "sustainable development" is increasingly penetrating various spheres of life, subordinating not only political interests, but also forcing economics and science to work closely together to preserve a favorable environment, biodiversity and reduce climate emissions. On the one hand, in the current global paradigm, this attitude is mainly positive, as it aims to achieve the goals of the Paris Climate Agreement, prevent negative environmental impacts and other high goals, including the protection of the interests of future generations. However, the "green fever" that is sweeping the world, namely the race of states and various international organizations, carries significant risks. The goals and economic targets set by Governments are sometimes not just overly ambitious, but simply unrealistic and utopian, as in the case of the transition to blue hydrogen in the next five years. In addition, another problem associated with the implementation of the principles of sustainable development is the problem of abuse of rights in the financial market, as well as increasing the competitiveness and attractiveness of investments in this area through the issuance of specialized securities, the so-called "green bonds" or their specialized variety of "blue bonds". However, it should be noted that with all the marketing activities that accompany the issuance of each financial instrument of this type, it is currently impossible to ensure their liquidity solely for supposed good purposes. Thus, without a clearly formulated economic plan confirming the real financial attractiveness of both projects on the introduction of blue water and projects on the issue of blue bonds, both are doomed to very low performance.

Keywords: sustainable development, green hydrogen, low carbon hydrogen, green taxonomy, European green deal, ESG principles, financial instruments, green bonds, blue bonds

I. Introduction

The main trends of the regional policy of sustainable development at the present time can be traced most clearly within the framework of the ongoing activities of the European Union (EU), since it is the institutions of this integrating organization that make it possible to cover all the diversity of social relations that are currently being built within the concept of ESG (economic, social, and corporate governance).

Several key factors can be identified in the trends of recent years. First of all, the strengthening of legal regulation, which is manifested firstly in the preferred form of adopted legislative acts, namely regulations that do not require an additional period for implementation, which in turn should encourage Member States to ensure their compliance as soon as possible.

Second, as exemplified by the so-called Green Taxonomy (Regulation (EU) 2020/852 of the European Parliament and of the Council of 18 June 2020 on the establishment of a framework to facilitate sustainable investment), the trend towards the adoption of framework legislation is expected to continue. This will come into force in 2020 and will create the necessary basis for the adoption of technical and other requirements on its basis, under the delegated powers of the European Commission, allowing for faster decision-making. The chosen mechanism will continue to be applied in the future, which is confirmed when more specific reference is made to the legal regulation of non-financial reporting or the establishment of a CBAM (Regulation (EU) 2023/956 of the European Parliament and of the Council of 10 May 2023 establishing a carbon border adjustment mechanism).

In particular, Regulation (EU) 2019/2088 on the disclosure of sustainability-related information in the financial services sector ("SFDR") and the technical standards adopted by the European Commission on April 6, 2022, in addition to the above regulation, are to be used by financial market participants for the disclosure of sustainability-related information (e.g. Commission Delegated Regulation (EU) 2022/1288 of 6 April 2022).

They contain pre-contractual templates detailing the disclosures in prospectuses required under the SFDR, including information on the taxonomy required for products under Articles 8 (environmental and social investments) and 9 (investments with a partially sustainable purpose), as well as templates for the disclosure of periodic reporting for such products in the relevant annexes.

Third, it should be noted that work on EU-wide adoption issues will continue in the future. The Green Taxonomy is a similar proposal in the area of social projects.

The EU Social Taxonomy, together with the previously adopted Green Taxonomy, is a set of measures developed within the European Union and aimed at promoting the implementation of the UN SDGs on "sustainable development".

As stated in the draft, the lack of a clear definition of the essential characteristics of social investments hampers their development and potential contribution to solving social problems. In particular, the lack of agreed standards and the large number of projects with the prefix "social" do not allow for a reasonable choice, including on the part of investors.

A social taxonomy can address these issues and harmonize the way social issues are measured, making it easier for investors to make informed and consistent decisions and helping to direct resources to socially responsible activities and companies. However, the mechanisms used to verify environmental and sustainable activities are not equally applicable to social development.

In its quest for regulatory uniformity in this area, the EU may be deviating from its own motto of "unity in diversity" in order to ensure formal equality where it is sometimes not only not economically advantageous but also not achievable due to the specificities of the socio-cultural environment.

Fourthly, it is important, in our view, to note the growing interest in alternative energy sources. This refers both to general requirements for the revision of the Renewable Energy Directive and more specific legislative proposals that are part of the Fit-for-55 program, such as the Directive on common rules for the internal markets for renewable gas, natural gas and hydrogen. The production of so-called “blue” hydrogen is now taking on an increasingly important role, including being seen as a substitute for other natural fossil fuels: coal and natural gas, and will therefore require a coordinated regulatory mechanism within the EU.

II. Green taxonomy as a legal framework for the realization of the concept

The term “taxonomy” is of Greek origin (“taxos” - structure, order, “nomos” - law) and was originally used exclusively in biology, to define the doctrine of the principles and practice of classification and systematization of plants [1].

Nowadays, the term developed and used in natural sciences has been borrowed and used by researchers as a definition of other classification systems, for example, "economic taxonomy" [2], "taxonomy of the educational system" [3], 'military taxonomy' [4] and 'taxonomy of sustainable (including) green development projects', which will be discussed below.

One cannot but agree that "the existence of various international bodies and organizations at both the universal, interregional, regional and subregional levels complicate the task of creating an effective system of economic development. There is therefore a need to strengthen coordination among them to avoid fragmentation and duplication of their functions and to ensure sustainable coherent development" [5].

Despite the fact that the experience of the European Union in the field of sustainable development and the creation of a complex structured system of verification of green projects is one of the best, it should also be emphasized that when developing its own taxonomy, the European legislator was guided by already existing acts in this field, such as the Taxonomy of Climate Bonds [6], as well as the Taxonomy of Green Projects [7].

The Green Project Taxonomy is a guide to climate-related assets and projects. It is a tool for issuers, investors, governments, and municipalities to help them understand which key investments will deliver a low-carbon economy. The taxonomy uses a traffic light system to identify suitable assets and projects (the ASEAN Taxonomy, among others, is built on the same principle) and includes sectoral criteria that provide details on which assets can be financed with climate-certified bonds and loans.

Regarding the Climate Bonds Taxonomy, this document, like the above-mentioned ones, creates a certain system of criteria for green (sustainable) development areas, with an indication of prioritization.

In any case, all previously developed acts are of a recommendatory nature and, existing since 2013, have not had such a noticeable impact on states or international organizations as the EU draft taxonomy.

The prerequisites for the creation of a special system of systematization and classification of "green" projects or "sustainable development projects" in the EU were the successive adoption of several fundamental acts.

The initial contributions to the taxonomy were the UN General Assembly Resolution establishing a new global framework for sustainable development: "Transforming our World: The 2030 Agenda for Sustainable Development" ("2030 Agenda"), which includes the Sustainable Development Goals (SDGs) and three dimensions of sustainability: economic, social and environmental, and the previously adopted Addis Ababa Action Agenda of the Third International Conference on Financing for Development (Addis Ababa).

The Addis Ababa Action Agenda has identified several global, cross-cutting areas in which there is a need for greater cooperation, both at the international level and State control at the national level. The areas of cooperation referred to in the programme are as broadly defined as possible (e.g., domestic public resources; private business and finance at the national and international levels; international development cooperation; international trade as an engine for development; debt and debt sustainability; addressing systemic issues; science, technology, innovation and capacity-building) and have a wide range of focus, including, at the same time, health issues, support for environmental projects, and support for the development of the environment.

Although the Sendai Framework is narrower in scope and focuses mainly, as the name suggests, on disaster risk reduction, the priority area of the Framework is "understanding disaster risk" through "collecting, analyzing, systematizing and using relevant data and practical information and ensuring its dissemination, taking into account the needs of different categories of users, as appropriate" (para. 24 (a) of the Framework).

As the researchers emphasize, it was "the Sendai Conference, which endorsed the UN

Framework for Disaster Risk Reduction 2015-2030, that gave impetus to international congresses and other activities at the national level" [8].

The second equally important factor was the adoption of the 2015 Paris Climate Agreement, endorsed by the European Union in 2016.

Thus, the provisions of the Paris Agreement stipulate strengthening the response to climate change "by aligning financial flows with greenhouse gas emission reduction and sustainable development" (Article 2 (1) (c)).

The adoption of the above-mentioned acts has, in turn, triggered an EU response. First, the European Commission in the Communication "Next steps for a sustainable European future. European Action for Sustainable Development" reaffirms its commitment to the principles of sustainable development in general and specific SDGs in particular, dividing the EU's future activities until 2030 into two areas: firstly, the full integration of the SDGs into the European policy framework and the current priorities of the European Commission, assessing the situation of the EU and identifying the most pressing sustainable development challenges, and secondly, analyzing the further development of the long-term vision and direction of sectoral policies after 2020, preparing for the long-term progress.

The subsequent Joint Statement of the Council of the EU and the representatives of the governments of the Member States meeting within the Council, the European Parliament and the Commission "A New European Consensus on Development. "Our World, Our Dignity, Our Future" 2017 (better known as the 'New European Consensus on Development') is essentially declaratory in nature and does not contain specific regulatory measures, unlike the subsequent European Commission's Action Plan "Financing for Sustainable Growth".

One of the objectives set out in the above-mentioned Financing for Sustainable Growth Action Plan is to "reorient capital flows towards sustainable investments to achieve sustainable and inclusive growth".

The creation of a single classification system for sustainable activities is the most important and urgent action envisioned by the Plan. Thus, it is explicitly stated that "the shift of capital flows towards more sustainable activities must be underpinned by a common holistic understanding of the environmental sustainability of activities and investments." And the first step in this journey should be the creation of clear guidance on environmental activities that will help inform investors about capital investments that finance environmentally sustainable economic activities. Further guidance on activities that contribute to other sustainable development goals, including social goals, can be developed at a later stage.

The Financing for Sustainable Growth action plan, together with the 2019 European Green Deal, has laid the groundwork for the European Parliament and Council to adopt a taxonomy to categorize environmentally sustainable activities.

Regulation (EU) 2020/852 of the European Parliament and of the Council of 18 June 2020 on the establishment of a framework to facilitate sustainable investment (better known as the "Taxonomy Regulation", hereinafter also "Regulation (EU) 2020/852") does not in fact contain such a term as "taxonomy", operating with the phrase "classification system for environmentally sustainable economic activities", which translates the EU climate and environmental objectives into criteria for specific economic activities for investment purposes.

It recognizes as "green" or "environmentally sustainable" economic activities that make a significant contribution to at least one of the EU's climate and environmental objectives, but at the same time do not significantly undermine the remaining five and minimum social safeguards.

The delegated acts on the taxonomy adopted under Regulation (EU) 2020/852 establish and maintain clear criteria for activities in order to define what is meant by 'significant contribution' and 'harm', and introduce mandatory disclosure obligations for certain companies and investors, requiring them to disclose their share of activities aligned with the taxonomy.

However, the EU taxonomy is not a mandatory list of economic activities in which investors must invest. Nor does it set mandatory environmental performance requirements for companies or financial products. Investors are allowed to freely choose their investment targets. However, over time, the EU taxonomy is expected to promote change and drive the transition to sustainable development.

It should be noted that economic activities that are not recognized by the delegated acts of the EU taxonomy as making a significant contribution to one of the EU's climate and environmental objectives are not necessarily environmentally harmful or unsustainable. Moreover, the delegated acts should be "living instruments" that will be supplemented and updated over time as necessary, as it is obviously not possible to define a complete list of possible environmentally beneficial activities overnight.

Considering the Taxonomy Regulation, we will conditionally distinguish two main directions of legal regulation: firstly, defining the criteria of sustainable development, and secondly, ensuring the functioning of the information disclosure system.

Characterizing the first direction of legal regulation, let us turn to the term "environmentally sustainable investments", defined as "investments in one or more types of economic activities that qualify as environmentally sustainable in accordance with the Taxonomy Regulation".

Thus, such activities must make a "significant contribution" to one of the six environmental objectives listed below:

-climate change mitigation;

-adaptation to climate change;

-sustainable use and protection of water and marine resources;

-transition to a circular economy;

-pollution prevention and control;

-protection and restoration of biodiversity and ecosystems.

It also defines four conditions that an economic activity must meet to be recognized as compliant with the EU taxonomy:

-making a significant contribution to at least one environmental objective;

-no significant harm to any other environmental objective;

-compliance with minimum social safeguards;

-compliance with the technical selection criteria.

The previously mentioned technical selection criteria are developed in delegated acts, in particular Commission Delegated Regulation (EU) 2021/2139 of 4 June 2021 supplementing Regulation (EU) 2020/852 of the European Parliament and of the Council by establishing the technical screening criteria for determining the conditions under which an economic activity qualifies as contributing substantially to climate change mitigation or climate change adaptation and for determining whether that economic activity causes no significant harm to any of the other environmental objectives. For each economic activity under consideration, the technical selection criteria define requirements for environmental performance that ensure that it makes a significant contribution to the environmental objective under consideration and, at the same time, does not cause significant harm to other environmental objectives.

In addition, the delegated legislation distinguishes between "enabling" and "transitional" economic activities.

Enabling economic activities "do not contribute significantly to climate change mitigation through their own activities".

Such activities play a crucial role in decarbonizing the economy by directly enabling other activities with low carbon and environmental performance. Therefore, technical selection criteria should be established for those economic activities that play an important role in ensuring that the targeted activities become low-carbon or reduce greenhouse gas emissions.

Transitional economic activities are “activities that cannot be replaced by technologically and economically feasible low-carbon alternatives but support the transition to a climate-neutral economy”.

These activities can play a crucial role in mitigating climate change by significantly reducing their current high carbon footprint, including by helping to phase out fossil fuels. Consequently, technical selection criteria should be established for those economic activities where near-zero carbon solutions are not yet viable, or where near-zero carbon activities are not yet feasible but not yet feasible at the scale that has the highest potential to significantly reduce greenhouse gas emissions.

It is worth noting that current practice shows that both above economic activities are currently speculative political instruments and subject to substantial lobbying, particularly where the gas and nuclear sectors of the economy are concerned.

The Delegated Regulation on Technical Criteria provides for two main Annexes - the technical screening criteria for determining the conditions under which an economic activity qualifies as contributing substantially to climate change mitigation and for determining whether that economic activity causes no significant harm to any of the other environmental objectives (Annex I) and the technical screening criteria for determining the conditions under which an economic activity qualifies as contributing substantially to climate change adaptation and for determining whether that economic activity causes no significant harm to any of the other environmental objectives (Annex II).

The Annexes include the following areas for green activities:

-forestry (e.g. afforestation);

-environmental protection and restoration (e.g., wetland restoration);

-manufacturing (e.g., production of energy-efficient building equipment);

-energy (e.g., electricity generation using solar photovoltaic technology);

-water, sewerage, waste management and remediation (e.g., construction, expansion and operation of a wastewater collection and treatment system);

-Transportation (e.g., conversion of inland waterborne passenger and freight transport);

-building and real estate (e.g., installation, maintenance, and repair of electric vehicle charging stations in buildings (and parking lots adjacent to buildings));

-information and communication (e.g., data-driven solutions to reduce greenhouse gas emissions);

-professional scientific and technical activities (e.g., research, development, and innovation in the direct capture of CO2 from the air).

The technical selection criteria for “significant contribution” to the environmental objective favors that the economic activity either has a significant positive environmental impact or significantly reduces a negative environmental impact, such as a significant reduction in greenhouse gas emissions.

The “no significant harm” technical selection criteria contribute to ensuring that the economic activity does not interfere with the achievement of other environmental objectives, i.e. does not have a significant negative impact on them.

The two sets of criteria together ensure consistency between the objectives of the EU taxonomy and ensure that progress towards one objective is not achieved at the expense of another.

The European Parliament and Council have prioritized the economic activities that can make the greatest relevant contribution to the two environmental objectives under consideration.

The first Delegated Act focuses on climate objectives (climate change mitigation and adaptation to climate change) and therefore includes activities that are most relevant for reducing greenhouse gas emissions and building resilience to climate change. This includes the sectors with the highest contribution to CO2 emissions (energy, manufacturing, transportation, construction) and activities that contribute to their transformation, as transforming activities in these sectors is necessary to achieve the EU's climate objectives.

In addition, so far, the Delegated Regulation on technical criteria reflects a fragile compromise on whether nuclear energy and natural gas should be included among the activities covered by the act.

On January 1, 2022, the European Commission launched a consultation with the Member States' Expert Group on Sustainable Finance and the Sustainable Finance Platform on the draft text of a Supplementary Delegated Regulation covering certain gas and nuclear activities.

The European Commission's Delegated Regulation would label investments in nuclear power plants as “green” if the project has a plan, means and site for the safe disposal of radioactive waste. In addition, to be considered green, new nuclear power plants must receive a construction permit by 2045.

Investments in natural gas-fired power plants will also be considered green if they produce emissions of less than 270 grams of CO2 equivalent per kilowatt-hour (kWh), replace more polluting fossil fuel-fired power plants, receive a construction permit by December 31, 2030, and plan to transition to low-carbon by the end of 2035.

Gas and nuclear power generation will be granted green status on the basis that they are “transitional” activities, defined as those that are not fully sustainable but have emissions below the industry average and do not fix polluting assets.

This draft has already generated several highly significant disputes. For example, EU member states such as France and Poland are actively pushing for the inclusion of nuclear energy in the taxonomy list, arguing that it is a critical low-carbon technology needed to ensure energy security while the EU transitions to renewable energy in the coming decades.

Along with Germany, other countries such as Austria or Luxembourg vehemently oppose such a move amid concerns about nuclear accidents and waste. They would like to see nuclear power disappear from the EU instead of encouraging the construction of new power plants through “green labeling” [9].

Supporters of natural gas argue that it is cleaner than coal and should be used as a transition fuel, while opponents believe it undermines the EU's environmental goals.

Regarding the second area - ensuring the functioning of the information disclosure system, we consider it necessary to note the following.

The Taxonomy Regulation, in conjunction with the other two acts, is intended to provide a single harmonized framework.

The Regulation defines certain mandatory disclosure rules. Alongside these, companies can also use the EU taxonomy on a voluntary basis.

Large financial and non-financial companies subject to the Non-Financial Reporting Directive (discussed in more detail below) will be required to disclose their environmental performance. Similarly, financial market participants (e.g. asset managers) will be required to disclose the extent to which the activities that their investment products finance meet the criteria of the EU taxonomy.

Separately, in our view, it is worth noting that there are many possible options for voluntary use of the EU taxonomy by market participants that are not defined in the documents. For example, companies can use the EU taxonomy criteria as a baseline for their environmental and sustainability strategies and transition plans. Companies and project organizers can also choose to meet the EU taxonomy criteria to attract investors interested in making green investments.

III. Blue hydrogen: pros and cons

Let us consider in more detail the problem of legal regulation of processes related to the creation, storage, circulation of such a renewable energy source as "sustainable" ("renewable" hydrogen).

Speaking about the peculiarities of the technological process, simplified, the procedure of its production is based on electrolysis, splitting water into oxygen and hydrogen, by using for this purpose other energy from other renewable sources (solar energy, wind energy, etc.).

Of its competitive advantages in the market of energy resources are:

-decarbonization of industry due to the abandonment of sources such as natural gas, oil and their derivatives, and nuclear power;

-significantly higher energy intensity compared to existing alternatives;

The possibility of long-term, large-scale storage of renewable hydrogen, including utilizing existing storage capacity for natural gas and liquefied natural gas;

-reduction of greenhouse gas emissions by at least 70%, which in turn is coordinated with the requirements of the Paris Climate Agreement and internal acts of the EU itself.

The legal basis for the system operation is laid down by several acts of the European Union. Thus, the definition of "low-carbon hydrogen" is given in the Renewable Energy Directive, and it is understood as "hydrogen the energy content of which is derived from non-renewable sources, which meets the greenhouse gas emission reduction threshold of 70 % compared to the fossil fuel comparator for renewable fuels of non-biological origin set out in the methodology for assessing greenhouse gas emissions savings from renewable fuels of non-biological origin and from recycled carbon fuels, adopted pursuant to Article 29a(3) of Directive (EU) 2018/2001".

At the same time with the above notion there are the following definitions: "renewable fuels of non-biological origin / renewable hydrogen" (Directive (EU) 2024/1788 of the European Parliament and of the Council of 13 June 2024 on common rules for the internal markets for renewable gas, natural gas and hydrogen (Art. 2, para. 11)) and "low carbon gas". In the former case, the term covers liquid and gaseous fuels whose energy content is derived from renewable sources other than biomass, while in the latter case it covers other fuels, i.e. much broader than just "low-carbon hydrogen", although it does cover it (Gas and Hydrogen Markets Directive (Art. 2 para. 12)).

At the same time, it is worth noting that, based on the literal interpretation of the Directive, none of the above-mentioned energy sources can be fully classified as "sustainable" according to the EU Green Taxonomy, as the latter, in turn, assumes a minimum of 73.4%.

It is difficult to assess what is the reason for such discrepancy and multiplicity of terminology of the European legislator. For example, the concept of creating "low-carbon fuels" represents the need to achieve ESG principles. At the same time, for such a complex in all senses technological process of production, achieving higher indicators may not lead to the development of technological processes, but on the contrary become an additional obstacle, including for investment.

However, despite the existing differences in terminology, the EU continues to pursue a coordinated policy of creating a legal framework and adopts several strategically important documents in addition to the above-mentioned ones: The Delegated Act on a methodology for renewable fuels on non-biological origin and the Delegated Act establishing a minimum threshold for greenhouse gas (GHG) emissions savings of recycled carbon fuels.

The first document establishes criteria under which hydrogen and other fuels based on it can be considered renewable fuels of non-biological origin (RFNBOs), while the other aims to set thresholds and considers such existing greenhouse gas emissions over the entire technological cycle, including the direct extraction process, subsequent refining and eventually transportation to consumers.

It considers greenhouse gas emissions throughout the entire life cycle of the fuel, including emissions during the extraction phase, emissions associated with obtaining electricity from the grid, emissions during refining, and emissions associated with the transportation of that fuel to the final consumer.

These criteria include, firstly, the additionality requirement that increased hydrogen production must be done in conjunction with new renewable electricity generation capacity, and secondly, the temporal and geographical correlation criterion. The latter is aimed at creating production facilities directly in those regions of the EU where renewable energy production is available. The very idea of the European legislator in this case is aimed at creating and encouraging the creation of specialized enterprises in the most suitable regions, including to reduce the use of fossil energy resources.

The main problem associated with the production of this kind of "renewable energy source" is the following factors. In order to achieve the necessary production of "blue hydrogen" on such a scale by currently known methods, a huge amount of energy resources is required, but the currently available alternative energy sources cannot provide such capacities. Therefore, the only possible source of energy in this case is fossil fuels, which is confirmed by the available data of the International Energy Agency [10].

The second negative factor in the production of blue hydrogen is the fact that the total emissions of negative substances into the atmosphere during its production are much higher than in the case of other energy sources, including natural gas [11].

Thus, at the moment we are talking about the fact that it is possible to question the initially existing idea justifying the necessity of its production exactly as an environmentally friendly energy source.

IV. Green and blue bonds

In addition to the delegated legislation on the EU taxonomy discussed earlier, a major achievement of European legislation has been the Regulation on European Green Bonds, the so-called "green bonds".

"Green bonds" are securities issued by the issuing company to finance specific projects aimed at minimizing the negative impact on the environment. If we omit the specific purpose, which is evident from the name itself, in essence, these bonds are still the same debt securities evidencing fixed-income financial obligations.

Despite the fact that this type of bonds is currently quite common all over the world and is widely used, for example, in Japan [12], it was the European Investment Bank in 2007 that first issued green bonds called "Climate Awareness Bonds" for the purpose of financial assistance to projects in the field of alternative energy sources. In turn, these assets received their current name thanks to the bonds of the same name issued by the International Bank for Reconstruction and Development [13].

Until recently, in order to acquire the status of "green", the issue of bonds must comply with special principles formulated by the international capital markets association, or meet the requirements of the organization "Climate Bonds Initiative", followed by a special confirmation.

The new EU Regulation is intended to replace the various existing standards and establish uniform criteria for issuing such bonds, preventing divergence of national requirements that may arise as a result of the adoption of a directive or adherence to other standards, not only for public but also for private entities, including those outside the EU.

Issuers that voluntarily use the designation "European Green Bonds" or "EuGB" should follow the same rules across the EU in order to increase market efficiency by reducing divergence and thus also reducing the cost of valuation of these bonds for investors.

The provisions of the draft Regulation imply, among others, the following:

-compliance with "transparency" requirements (in order to allocate bond proceeds through detailed reporting requirements);

-"external verification" (hiring an external expert to conduct the compliance procedure);

-"supervision by the European Securities Markets Authority (ESMA) of external experts" (the latter must be registered with and supervised by ESMA).

While the EU is "treading water" and considering additional measures to integrate the financial sector into the "sustainable agenda," much more promising projects are emerging in other regions.

In particular, with the support of the Asian Development Bank, countries in the region have revised the classic structure of the European Green Bond and created a new investment product based on it - Blue Bonds [14, 15]. Belize, Barbados, the Seychelles and Gabon are following suit [16].

Developing a sustainable blue economy, including reversing the decline of marine fisheries, expanding low-carbon aquaculture, scaling up marine renewable energy, and decarbonizing maritime transport, is an integral part of addressing the triple planetary crisis of a rapidly changing climate loss and pollution of nature. The ocean is a vital sink for heat and carbon.

V. Conclusion

When we talk about sustainable development, we are not just talking about the need to protect the environment at a particular point in time, but also to make a contribution to the future. Thus, it is not so much about the need to incentivize investment in high-risk projects, but rather about investing for future generations.

Nevertheless, the existing initiatives analyzed in this paper are currently more populist in nature and have little current feasibility.

However, despite all the negative arguments against "blue hydrogen" as a "renewable energy source", as well as with regard to the little promising and practically nowhere used in practice "blue bonds", both of these projects carry significant value in terms of possible development directions, which should be improved, strengthened and supported in many ways, both economic and legal, and therefore cannot be canceled completely.

Abstract

In this article, the development of new research methods and methods for the assessment of personnel composition, the determination of personnel resources in industrial enterprises, as well as the issues of their efficient placement and bringing labor productivity to the maximum level were discussed. Thus, the selection of employees within equal opportunities based on the competition organized on the basis of certain laws, the creation of a social security system for each employee and the consideration of the effective activity and full protection of the rights of that employee during the period of operation, the continuous operation of employees, cases of absence. In order to prevent and continuously maintain development, the possibilities of conducting internal and external trainings, directing employees to appropriate maintenance activities based on effective placement, training additional reserve personnel for management positions and giving instructions based on their duties have been investigated and evaluated. The model of formation of the innovation potential of the personnel in the industrial enterprise was established and the ways of efficient use of the existing potential of the personnel were studied.

Keywords: personnel policy, personnel turnover, labor productivity, wages, personnel resources

I. Introduction

The evaluation and efficient placement of personnel in terms of composition is one of the important factors to be noted in the field of the economy as well as in the industrial enterprise in general. In general, the study of this issue and the work on this topic have been given more space in recent times. Especially if we look at the last century and the times when the industry first appeared, we can see that there was no serious approach to the study of personnel composition. This situation became widespread after the emergence and development of science and technology. The emergence of such an issue created a basis for the correct evaluation and efficient placement of personnel, the investigation of the reasons for their low productivity and improper organization of work in this direction.

Looking at the modern era compared to the previous period, we can see that the personnel policy incorporates certain radical changes as well as further development. For example, it can be noted that before, the regulation of personnel turnover was carried out in an irregular manner and without any laws or restrictions. There are a number of national factors of competitiveness, which we can attribute to highly qualified personnel and motivated workforce from material and moral point of view. In earlier times, these factors were studied in a completely different way. Because at that time, land, capital, and natural resources were dominant. We can even see it clearly during migration. If the early times were mainly based on "muscle power", nowadays "brain power" plays an important role [2].

If we look at the studies of economists, it would be more correct to start with the works of Adam Smith and David Ricardo. Thus, in 1776 Adam Smith's "Inquiry about nations and the causes of their wealth" and in 1817 David Ricardo's book "Principles of Political Economy and Taxation" noted that labor acts as an important element in the economy between the personnel potential and the value category. was done. Regarding economic relations, the opinions of Elton Mayo and F. Rosthlisberger based on their research were correctly reflected. Both economists studied for a long time the impact of the physical factors identified in the factories of the "Western Electric Company" in Chicago on the productivity of workers [7].

As a result, Mayo created the theory of "social system" and his research proved once again that the important system in enterprise organization is "social system" and its important subject is "man". In general, Mayo came to the following conclusions:

- Each employee operating in the enterprise has a unique character and is variable;
- Every economic interest does not have the main role for the spent activity;
- It is impossible to be sure that the group or groups formed in terms of a number of functions are an exemplary group [7].

It is possible to think in two ways, firstly, the low level of personnel turnover reduces the negative effects on labor productivity. The explanation of this idea is mainly explained by the direct and indirect costs, which include employee turnover. Economists justified the mentioned arguments through a number of theories. For example: the English economist Ian Shaw in his book published in 2005 under the title "Circulation, Social Capital Losses and Productivity (Performance)" linked human and capital theories. Kato and Yanadori's 2007 book "Average Employee Tenure, Voluntary Turnover Rate, and Labor Productivity" proved the idea based on organizational disruption framework theory. American economist and sociologist Gerry Becker's 2004 book, Organizational Rules: Industry and Corporate Change, also made a connection with Ian Shaun's theory of man and capital. In general, Berker and Shaw noted that human and capital theory have an important role in increasing the labor productivity of employees and enterprises. A more extensive explanation of this argument is provided by writers in the following format: Park and Kim 2013 "Turnover rates and organizational performance", J.B and Barney "Enterprise resources and sustainable competitive advantage", Lepak and Snell "Human resource architecture" [10].

In the book "Voluntary turnover, social capital and organizational performance", Des and Shau generally classified the damage caused by personnel turnover to the productivity of the enterprise in 2 formats:

- In general, the inability of an enterprise to positively see the result of the capital invested in employees;
- Damages caused to the competitiveness of the enterprise due to the loss of capital in terms of employees [1].

Hausnext noted that the staffing flow has caused a number of operational delays at the enterprise, which he claims have ultimately had strong operational implications. The flow of personnel directly and indirectly affects the functioning of the enterprise. As an example of an indirect way, the time and financial costs spent on hiring new replacement employees, socializing them, familiarizing them with the work environment and learning the work process, and increasing their personal development by being involved in training. Directly, we can mention missed work opportunities due to unfulfilled obligations, unfinished work, lack of personnel in the enterprise for specialties, and lack of sufficient information about the process in the replaced employees. In all of these cases, as a result, it leads to a linear decrease in labor productivity and a delay in the execution process of operations. Looking at this issue from another point of view, Ian Shaw proposed several nonlinear relationships [8].

For the first time in economics science, personnel evaluation appeared in the United States at the beginning of the 20th century. For this reason, as a number of businesses developed, new methods and methodologies, methodological approaches were formed. If we look at the evaluation of personnel in Azerbaijan for the modern era, we can see the use of a number of methods. These methods are widely used: interview, testing, standard, self-report, descriptive, compulsory selection, etc. is attributed. Each of the mentioned methods has its own disadvantages. In an era where science and technology are developing, new methods of staff evaluation are being sought and researched. The main reason for this is to achieve a more active evaluation of self-evaluation elements.

If we look at the process of management or personnel management, a number of evaluation methods are studied in the works written by many economists. As an example of economists, M.B. Kurbatova, V.E. Khrutsky, M.I. Magura et al. I can mention the methods analyzed by them: 360-degree assessment, method of written characteristics, self-assessment, management by goals, method of rating table of behavioral relations, method of evaluating the level of observation based on behavioral observations [12].

Evaluation and comprehensive study of personnel resources in industrial enterprises is based on a certain system, which in itself combines 3 aspects. The first is the study of the ability of each employee individually and the evaluation of the ability from the point of view of objectivity. The second aspect is the determination of the appropriate requirements for the heads of any department. Finally, I would like to note that every manager prepares a personnel plan [3].

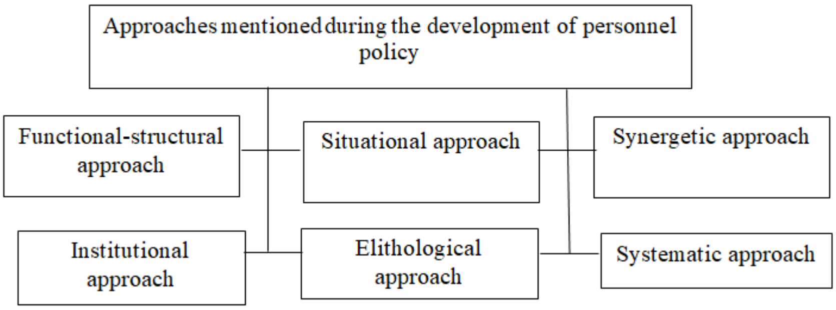

Figure 1: *Directions of personnel policy development*

In each tradition of statecontrol, a number of approaches are especially noted when the state's unique personnel policy is developed:

- Functional-structural approach - the role of labor resources is quite large and is aimed at the classification of functions, differentiation of the management system.

-Situational approach - at this time, the most productive effect is determined, and its determination is carried out on the basis of a specific situation. The form of influence determined at this time is evaluated as the form of influence corresponding to the current situation.

-Synergetic approach - firstly, the principle of self-organization is taken as an important quality characteristic.

- Institutional approach - research is given a wide place and its object is industrial enterprises and their aggregates, which play an important role in the development of personnel policy.

- Elitological approach - the study of the approach is directly related to the study of the concept of "elite". At this time, the study of officials, officials, and government officials is carried out in separate groups.

- Systematic approach - the state studies the elements that form its system and the qualities associated with it in the form of an integrative system [5].

When we study and research human resources in the field of economy, we can note the use of various methods and methods in personnel evaluation. Figure 2 shows the performance evaluation methods.

One of the main goals of every enterprise is to improve labor productivity and take a leading position in a competitive environment. For this, a strategic plan should be prepared properly.

- In any company, there is a need to ensure effectiveness and plan the training process, which is diverse across sectors. The use of the "Efficiency analysis and training planning" methodology in the company or any enterprise together with a number of official and unofficial documents made it possible to achieve certain results:təlim planının formalaşdırılması;

- determination of training priorities;
- collection, analysis and generalization of training needs of the structural unit;
- making changes to the training catalog;
- evaluation and analysis of the effectiveness of the training and development process [9].

When applying the mentioned methods, the Target operating model, Talent Management Concept, etc. the methodology is considered as the main document and the methodology plays an important role during the implementation of a number of processes. Here are some important factors to consider:

- training needs that have arisen in accordance with the requirements of any individual development plan;
- training needs resulting from the analysis of the company's predetermined strategy and development plan;
- Making necessary changes in the analysis of the results during the assessment of training effectiveness and the training needs that may arise as a result of it;
- Training needs that have arisen after the analysis of training on various indicators collected from a number of units based on previous periods.

Monitoring results play a key role when efficiency is analyzed. At this time, feedback requests should be taken seriously [4].

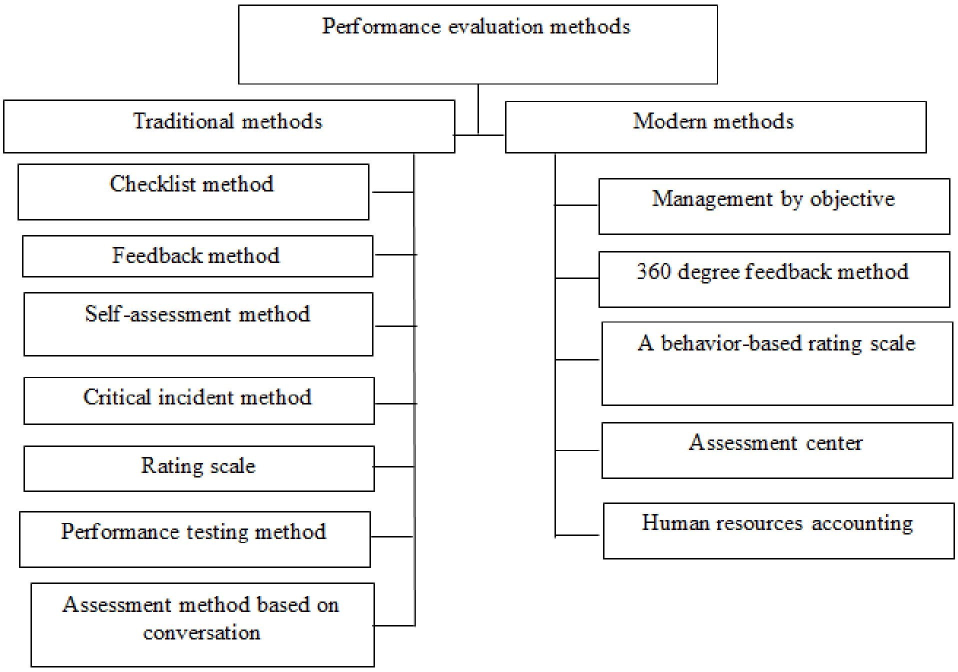

Figure 2: *Performance evaluation methods*

We get the following model based on the number of employees in the industrial enterprise and the costs incurred for the development of personnel, the volume of production for years.

Based on the MS Excel program, the coefficients of the linear regression equation between the number of employees, the volume of production, wages and other similar social payments and labor productivity in SOCAR are obtained as follows:

$$a_0 = 874{,}2;\ a_1 = -0{,}0186;\ a_2 = 1{,}85\ ;\ a_3 = 0{,}255$$

So the regression equation we are looking for will be:

$$y=-0{,}0186X1+1{,}85X2+0{,}255X3+874{,}2 \quad (1)$$

According to the Excel program, between the number of employees in SOCAR, the volume of production, wages and other social payments equivalent to it, and labor productivity, expressed by the linear regression equation y=-0.0186X1+1.85X2+0.255X3+874.2, functional there is a high correlation relationship very close to dependence (R^2= 0.99867). The degree of dependence between indicators According to the Chaddock scale, the quantitative indicator of relationship density in the range of 0.9-0.99 means that the qualitative characteristic of the strength of relationship dependence is quite high [6].

Table 1: *Dynamics of factors affecting labor productivity at SOCAR "Azneft" PU over the years*

Years	The number of employees (person)	Volume of production (tonns)	Wages and other payments (mln. Man.)	Labor productivity
2013	70901	54403408,5	662,67	767,3151084
2014	65568	65518306,26	660,39	999,2421038
2015	56460	60324885,39	597,62	1068,453514
2016	52576	66055570,2	563,68	1256,382574
2017	50933	68087692,82	595,68	1336,809
2018	50122	85545156,24	628,14	1706,738682
2019	50332	91434932,16	682,15	1816,636179
2020	51092	106135780	763,18	2077,346355
2021	50968	99329125,2	821,49	1948,852715
2022	48254	88692674,88	787,35	1838,037777

According to the established relationship equation, it can be concluded that with one unit increase in the number of employees in SOCAR, labor productivity decreases by 0.02 units, with one unit increase in production volume, labor productivity increases by 1.85 units, wages and equivalent One unit increase in other social payments results in an increase in labor productivity by 0.255 units.

As can be seen, according to the obtained table, model (1) is statistically significant. This significance is primarily explained by the fact that the coefficients of the free variables X and the free threshold C are significantly higher than their standard errors. It should be noted that the elasticity coefficient is calculated based on the following formula, expressing the percent increase or decrease of the dependent variable due to the 1% increase of the independent variable X included in the model [6].

$$E = \frac{\propto_i \times \bar{x}_i}{\bar{y}} \tag{2}$$

Here, α_i are the coefficients of the above relationship equation. x ̅- is the average of the number of employees, the volume of production, wages and other similar social payments and labor productivity in SOCAR for the studied periods. The elasticity coefficients calculated based on those indicators will be as follows according to the established model.

$$E_{n.e.} = \frac{\propto_1 \times \overline{x_1}}{\bar{y}} = \frac{-0{,}0186 \times 54720{,}6}{1481{,}581401} = -0{,}68716 \tag{3}$$

$$E_{v.p.} = \frac{\propto_1 \times \overline{x_1}}{\bar{y}} = \frac{1{,}85 \times 78552753{,}1}{1481{,}581401} = 0{,}980819215 \tag{4}$$

$$E_s = \frac{\propto_1 \times \overline{x_1}}{\bar{y}} = \frac{0{,}25 \times 676{,}235}{1481{,}581401} = 0{,}116314049 \tag{5}$$

The calculations show that with a 1% increase in the number of employees in SOCAR, a 0.69% decrease in labor productivity, a 1% increase in the volume of production, a 0.98% increase in labor productivity, and a 1% decrease in wages and other similar social payments. increase results in a 0.12% increase in labor productivity.

Figure 3 shows the production volume forecast model for the next 10 years in SOCAR "Azneft" PU, taking into account the number of employees.

Regardless of the sphere of activity, every enterprise wants the development of its personnel potential to be more extensive and modern, but for this, of course, the unique potential of its personnel should be evaluated. In addition to these, it is possible to mention the use of a number of models that are widely used in modern times. As examples of these models, it would be more correct to mention ADDIE and Bloom Taxcomony.

The essence of the ADDIE model is the planning of learning experiences and their implementation by developers and instructors. In terms of content, the model itself combines 5 parts: analysis, design, development, implementation, evaluation. This model includes stages in itself and assumes their consistent, orderly implementation [10].

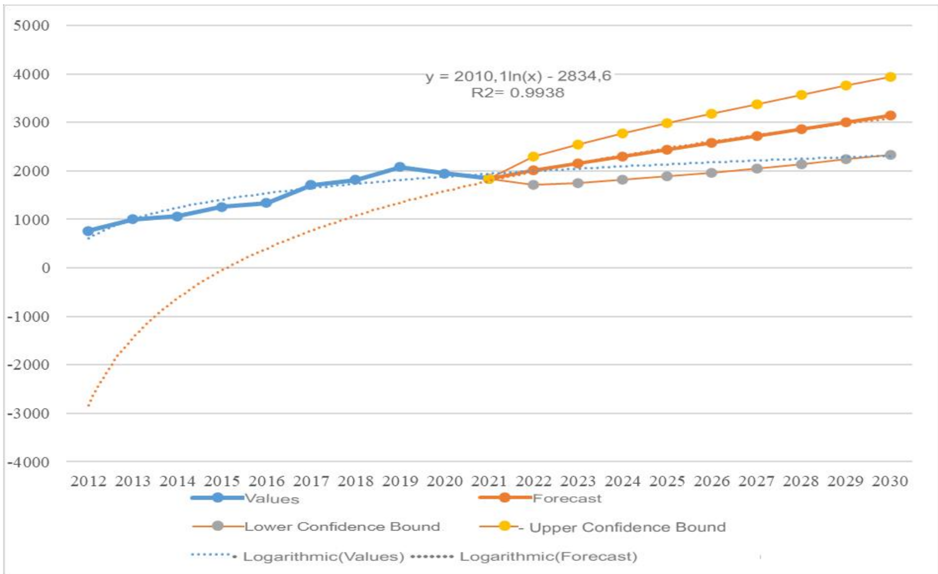

Figure 3: *Analysis of the production volume in SOCAR "Azneft" BU for the next 10 years in terms of the number of employees*

1. Analysis – initially the current situation should be analyzed and the gaps should be filled. For this, it is important to know where everything is prepared. According to the analysis, the qualitative analysis is specifically distinguished in that it enables the identification of goals and objectives for learning.

2. Design – decisions related to the creation of learning programs are made after all the information in the analysis is considered. It requires acceleration in terms of time and attention plays an important role.

3. After the content ideas are decided in the development-design stage, the implementation of those content ideas can be started. At this time, videos are written, graphics are created, fonts and colors are taken care of, visual design is done, etc.

4. Implementation - it is time for employees to complete the course after all the work is completed during the training. At this time, attention is paid to whether they face any problem or whether everything goes well.

5. Evaluation - finally, the evaluation process is carried out and the extent to which employees are satisfied and dissatisfied with the training is comprehensively studied.

Advantages of the ADDIE model: simple measurement of time and costs; to be more effective for learning; plays an important role for a number of models; widely accepted and used globally.

Disadvantages of the ADDIE model: it does not allow repetitive design; it takes a lot of time and is expensive; it is a rigorous process in terms of consistency; it is slower to adapt to sudden project changes.

Bloom's Taxonomy is basically a system that categorizes a set of dominant skills into specific domains of requirements. At this time, it is learned from the simplest skill to the most complex skill. If we look at the history of Bloom's Taxonomy, it was created in 1954 by Benjamin Bloom and his allies Walter Hill, Edward Furst, Max Englehart, etc. mentioned in the book "Taxonomy of Educational Objectives" published by others. So, the main factors that are important to note are based on the order of cognitive skills: understanding, knowledge, application, analysis, synthesis, evaluation. Bloom's taxonomy emphasizes 3 levels to study:

- Cognitive learning is the process of acquiring knowledge based on certain cognition and their mental skills.
- Affective learning - includes the development of certain feelings and a number of emotional areas, learning to analyze and explore them.
- Psychomotor learning - in this case, physical and experiential skills are considered as an important factor, which requires some time to be studied as a broad process.

As a result, it can be noted that this process or theory is intended to be applied in the enterprises of many countries. It is more desirable to apply Bloom's Taxonomy for future periods. However, work is being done in the direction of the development of the theory, in which the existing techniques and technologies of the time are taken into account[11].

One important factor to emphasize is the staffing process. As a definition of the process, it can be noted that it means placing the employee in departments or positions, taking into account his personal qualities. A number of aspects should be considered during deployment. It is very important to correctly determine the demand of organizations, enterprises, and firms for certain tasks for the future period. Even if the requirements for specialists with diplomas are determined, the use of a number of methods during forecasting is especially valued:

1. Normative method - volume of production, volume of work, labor standards intended for specialists
2. Staff nomenclature method - increase and decrease in the number of positions, qualifications based on positions, staff tables
3. Staff nomenclature method - increase and decrease in the number of positions, qualifications based on positions, staff tables

One of the nuances that is important to note is the identification of high- and very-high-important tasks during the placement of personnel. For this, the enterprise develops a certain methodology. The methodology defines appropriate solutions and methods of their application in order to implement the process of identifying high and very high importance tasks. This document is an integral part of the "Training of Attendees" methodology. During the implementation of the process of training participants, the use of the methodology "Determination of high and very high importance tasks" together with other related documents will serve to achieve the following results:

- Determination of high and very high importance tasks;
- Approval of the catalog of high and very high importance positions for the Company;

The following documents were used in the development of the methodology: concept of talent management; target operating model; charts for identifying high priority tasks for training followers; project solution on the main provisions; project solution for training followers.Metodika üzrə hədəf qrupları aşağıda göstərilmişdir:

- Specialist in the training of trainees;
- A specialist performing the functions of an IR partner
- Heads of structural units;
- Business experts;
- Employees working in high and very high importance positions.

During the development of the methodology, the concept of Talent Management, Target Operating Model, process diagrams and project solutions were based. In case of inconsistency between the methodology and the above-mentioned documents, the methodology is taken as the main document and is referred to during the implementation of the processes.

II. Conclusion and recommendations

1. The conducted regression calculations show that a 1% increase in the number of employees in SOCAR, a 0.69% decrease in labor productivity, a 1% increase in the volume of production, a 0.98% increase in labor productivity, and a 1% increase in wages and other similar social payments % increase and results in 0.12% increase in labor productivity.

2. Based on the dynamics of changes in the number of employees for 10 years, a model for forecasting the production volume was proposed for SOCAR "Azneft" PU, which is the research object.

3. Regardless of the sphere of activity, the unique potential of each enterprise's personnel should be evaluated so that the development of personnel potential is broader and more modern. For this purpose, it is more correct to use ADDIE and Bloom Taxconomy models.

4. Taking into account the employee's personal qualities, a methodology is proposed for determining high and very important tasks during his placement in departments or positions and personnel placement.

Abstract

The article studies the role of human potential in the development of modern socio-economic systems and its impact on their sustainability. A retrospective look at sustainable development and the influence of human potential on modern social and economic processes allows to generate a forecast of possible risks and threats in the conditions of digital transformation.
The authors highlight the threats that have become a reality in the modern development of society and that have a negative impact on the strengthening of human potential and the sustainability of socio-economic systems.
It is noted that the decline in demand for human capital in economic activity against the background of the introduction of digital systems that ensure productivity can lead to global negative social, economic, political consequences.

Keywords: sustainable development, digitalization, human capital, human potential, economic growth

I. Introduction

In the context of digital transformation, the development of socio-economic systems of the countries of the world is faced with a number of emerging problems; one of the most acute and uncertain is the problem of preserving and revealing human potential.

The sustainability of social and economic systems supposes such a state and development, in which the basics of the life activity of the entire society will not be disturbed: preserving the environment, providing conditions for saving the population, creating opportunities for self-realization and personal growth of citizens.

Man has always been the center of all ongoing processes in society and played a decisive role in the system of sustainable development. At the same time, "Sustainable development" itself (the term was first used in the Report of the United Nations Conference on Environment and Development in Rio De Janeiro, 1992) was presented in the context of increasing environmental risks, which made it possible to take a new look at the problems of environmental pollution as a result of destructive human activities.

The proclamation of the principle of sustainable development has changed the perception of the conceptual approach to the issues of movement and improvement of socio-economic systems, whose important and determining factor in the sustainability is the balance of human activity in the environment, economy, and social sphere.

II. Methods

The main goal of sustainable development is to ensure the growth of human well-being without disrupting the quality of the environment. There is some contradiction in this.

On the one hand, a person, in his strive to improve the quality and standard of living, uses all the resources at his disposal, often ignoring an economical and rational approach to natural resources and the environment. On the other hand, growth in the well-being of people and their next generations is possible only in case of maintaining the quality of the environment.

In this regard, there is a need for a systematic and comprehensive approach to solving this problem, requiring political will, understanding of economic feasibility and social responsibility of all members of society.

Acting as the central link of the entire eco-socio-ecological system, man is not a passive user, but an active participant, a subject of all processes, taking an active part in their formation and movement, realization of goals and control over their achievement. Therefore, the disclosure and use of his potential in modern society is a determining factor of economic growth.

The purpose of the study is to determine the place and importance of the human factor in the conditions of digital transformation, associated with a number of threats to the reduction of human potential disclosure.

Two groups of applied research methods contributed to the achievement of the goal: theoretical and empirical.

III. Results

Human potential, being a set of spiritual and physical forces such as knowledge, skills, talents, capabilities, abilities, contributes to decision-making to achieve personal and social goals. This potential is the driving force of socio-economic progress, but in case of disclosing of its two qualities: instrumental, allowing to shape the environment and living conditions and existential, revealing and enhancing a human's personal qualities, abilities and capabilities.

Initially, the concept of human potential in economics was described by Nobel Prize winner Amartya Sen, who defined human potential as the possibility to freely choose value-oriented activities. Sen became the founder of the theory of human capabilities, which became the goal and means of economic development and growth. The perception of human potential in the context of opportunities has become classic over time, but in the mid-2000s a new approach to revealing human potential through a person's whole internal abilities, personal qualities, creativity, cognitive and communication abilities, and non-cognitive skills began to gain popularity.

In recent years, particular importance has been attached to the revealing non-cognitive human skills, since it is openness to new experience, sociability, compromise, conscientiousness and extraversion that contribute to decision-making in conditions of uncertainty and change.

In the modern world, the development of human potential, as the main resource for increasing national wealth, is seen in the development of a set of fundamental factors of an effective individual:

- the factor of education that allows to improve professional skills, adapt to and navigate changing environment. The importance of self-development determines the prospects for future changes and allows improving knowledge and skills of the future, such as digital literacy, critical thinking, communication skills, etc.;
- the factor of development of entrepreneurial and innovative initiatives. Entrepreneurship and innovation are now in the focus of attention of organizational and management structures of the world countries, since they are the trend of sustainable development of socio-economic systems. All conditions are created for their maintenance and development: tax incentives, financial support, information and administrative support;

➢ the factor of social protection and inclusivity. A modern vision of sustainable development based on revealing human potential cannot be achieved without reducing inequalities. Within the framework of the implemented state policies of various countries, the problem of inequality is among the most important and requires immediate action to provide the population with equal opportunities for access to healthcare, education, and cultural growth. The social orientation and inclusivity of national government systems is a determining condition for sustainable development and growth;

➢ the factor of interaction of all social groups, government structures, business, scientific community on terms of partnership and synergy. The synergetic approach, in contrast to the compromise one, supposes achieving such coordination between all subjects of socio-economic relations in which all interests will be considered.

The modern world is undergoing global changes associated with rapidly occurring digitalization processes, which radically changes the paradigm of the use of human potential and human capital. As before, human capital is the main factor of production, surpassing financial and natural resources in terms of influence on sustainable growth. However, the development of artificial intelligence and the introduction of its functionality into the life of society creates new threats not only to the stability of socio-economic systems, but also to human identification in general.

The development of mankind has always been accompanied by new achievements, the level and qualitative components of which corresponded to each historical stage. Scientific and technological progress acts as a trigger for processes of rapid development and qualitative changes that bring additional convenience, benefits and opportunities to the entire society.

Modern technologies have completely changed the traditional mechanisms of functioning and management of socio-economic systems. Society receives many additional benefits from the development of convergent nano-, bio-, and information technologies, which create and allow functioning effectively complicated self-organizing complexes (ecosystems). Digitalization of significant social, political, business and economic functions of people is taking place, replacing their activity.

This creates real conveniences for mankind: the quality of life is changing, opportunities for self-development and growth in an extensive information environment are expanding, and there appears time for spiritual and cultural growth.

Serious threats arise despite the obviousness and inevitability of digitalization processes, which are still being introduced into the life of society pointwise, but will become widespread in the near future.

First of all, this is the threat to the fragility of the technogenic world, its dependence on minor technical failures, when all information resources can be lost, or access to them will be stopped (the phrase "plug-dependent civilization" is well-known).

An important problem in the context of dynamic digitalization is its infrastructure support. The underdevelopment of digital infrastructure, insufficient and heterogeneous material and technical support for innovation, differentiated and limited access to digital resources for all final consumers create concerns about such accelerated digitalization.

Cybersecurity is becoming a key problem in preserving not only personal data, but statehood as a whole. The functioning of the global virtual space has no limits and, therefore, is not subjected to regulation by national legal norms in the exchange of information.

Negative consequences of digital transformation do not end with the above-mentioned risks and threats, despite the fact that their damage to human potential development is obvious. One of the serious problems of digitalization for man is the gradual displacement of labor force, substitution of many functional elements of a modern economy with automated systems.

The introduction of modern technologies based on artificial intelligence (AI) into production processes leads to a productivity growth, but the result is a separation of business productivity from labor productivity, which leads to negative social consequences.

The productivity growth of economic entities, in isolation from the growth of labor productivity, will lead to an uneven distribution of the resulting benefits. The beneficiaries will be only a few (owners, shareholders), which will provoke an even greater increase in inequality and widen the gaps between segments of the population.

The threats and risks of digitalization in the political sphere are primarily threats to social stability and sustainable development.

Experts believe that one of the main risks of the new technological society is that full-scale robotization of production can cause colossal imbalances between supply and demand in the labor market.

Many researchers consider this threat to be extremely important, due to its obvious reality, and call on governments to define at the legislative level a list of professions that should be assigned to people. Otherwise, a significant part of the population, which becomes free of work, may suffer negative consequences of drug addiction, alcoholism, gambling addiction, etc.

The growth of social inequality in the context of the above-mentioned problem is inconsistent with the concept of human development, entails not only threats of inequality, but also an increase in the fiscal burden on budgetary systems, at the expense of which the states will smooth the gaps in the level of well-being of the population.

Developing the threat of inequality, it can be assumed that a certain category of citizens, being unemployed and without savings, risks losing access to other social services: health care, education, culture and sports. Professional skills and motivation for self-development and retraining will gradually be lost.

The loss of human potential due to the emerging challenges of digital transformation is becoming one of the most pressing problems that concern not only the social sphere, but also penetrate and will impact all components of socio-economic systems.

However, the most serious threat is not the material and spiritual components of the problem (their importance cannot be excluded), but the global problem of the loss of human identification as a biological species. This will cause a global collapse, which may result in a transition from self-development to self-destruction.

IV. Discussions and conclusions

So, the negative consequences of digitalization in the socio-economic environment, leading to the loss of human potential, include:

- loss of workplaces and growth of unemployment;
- increasing the efforts (administrative, financial) of states to ensure retraining and reeducation of citizens, increasing their financial literacy in the face of growing fraud risks;
- increased digital fraud, piracy and the spread of malicious information;
- unauthorized use of personal data resulting in financial, property and other losses;
- illegal use of personal data for the purpose of abuse, data diddling, etc.

The emerging new world generates and scales up tasks to preserve human potential, since its modern configuration creates significantly more threats than benefits for preserving the role and importance of human beings in sustainable and progressive development.

Currently, against the background of geopolitical contradictions, there is no agreement between the leading countries of the world on systematic work towards preserving human potential and its transformation and effective use as human capital in the economic interests of the world community.

There is also no agreement on the issues of maintaining work motivation and guaranteeing the professional demand of the population in the context of digital transformation.

According to the 2030 Agenda, the EAEU has outlined a range of problems for human potential development, recognizing that the time has come for decisive action for its development and implementation within the framework of obligations to achieve Sustainable Development Goals, expanding the horizons of interaction within the framework of this economic integration project.

Abstract

Assessment and management of investment risks are key aspects of successful investing, requiring special knowledge and strategies. Risk analysis and forecasting methods help investors make reasonable decisions and minimize potential losses. Effective risk management allows to minimize losses and maximize investment returns. To achieve these goals, various methods and strategies must be used. However, successful investing requires not only the ability to assess risks, but also to develop effective strategies for their management. Constant monitoring of the situation in financial markets, analysis of economic and political events, as well as the ability to quickly respond to changes will help to reduce risks and increase investment returns. This article considers the features of investment activity; the factors playing the most significant role in assessing the risk of investment projects; it also provides a classification of investment risks, determines their essence and causes of occurrence, as well as methods for their determination.

Keywords: investment risks, assessment methods, risk management, investment strategies, investment returns, risk analysis, financial instruments

I. Introduction

Investment activity is one of the most popular topics in the modern economic sphere of human activity. Popularity of investment activity has increased significantly with the increase in the level of financial literacy of the population. There is an understanding of how much investments help stabilize an individual's financial situation in a modern market economy.

The investment industry is a complex structure that includes various types of assets (shares, real estate, precious metals, derivatives, etc.). To get involved in investment activities as comfortably and easily as possible, it is necessary to study the basic concepts, structural elements, investment tools and strategies, types of assets, etc. It is understanding and knowing the answers to these questions that will allow you to minimize losses and maximize profits in the course of various investment activities.

Investment risks represent the probability of shortfall or complete loss of profit and/or invested assets in the course of implementation of investment projects where the object is the property interests of the investor.

The article examines methods of investment risk assessment and management, investigates quantitative and qualitative methods of assessment, diversification and hedging strategies, and defines the role of risk management in the overall investment process.

II. Methods

In the course of this synthetic research, the materials included publications in scientific journals referring to this issue, educational materials and textbooks related to the topic of the work, statistical data posted on the websites of the State Statistics Service, as well as the results of studies conducted in this area earlier. The main tools are observations, surveys and focus group discussions. Methods of logical and statistical analysis were also used in the research.

III. Results

Any activity related to the field of investment, as a type of commercial activity, is based on a number of features that significantly influence the process of determining the amount of investment risk. Multiple diversity of investment measures, that differ significantly both in their profitability and the level of inherent risk, significantly complicates the optimization of the investment portfolio. In addition, this area is the most susceptible to external economic, political and social effects.

Duration of the life cycle of the investment project; Due to the large scatter, it is quite difficult to take into account the 2 previous points and qualitatively and effectively predict the influence of factors on the profitability of an investment project and the amount of investment risk. Insufficient and sometimes complete absence of statistical data from the previous period on which one could rely when choosing tactics.

One of the main factors that directly influences the process of investment risk assessment is the degree of market volatility. The higher the volatility, the greater the opportunity for high profits, but the risk of loss also increases. As it is known, high volatility in economic theory indicates frequent and significant fluctuations in the value of an asset, wherein value fluctuations often exceeding 10% of the base value. With low volatility, prices are less susceptible to sudden fluctuations and price fluctuations do not exceed 2% of the base price.

Another important factor, in our opinion, is the degree of liquidity of investments. Illiquid assets may be difficult to sell in case of quick conversion into cash, that significantly increases investment risks. Liquidity is calculated using the following formula:

$$k = \frac{\mathrm{A1} + \mathrm{A2} + \mathrm{A3}}{\mathrm{P1} + \mathrm{P2}} \tag{1}$$

Where A1, A2, A3 are assets, and P1 and P2 are current and short-term liabilities, respectively. Another way to calculate the liquidity ratio is the ratio of current assets to short-term liabilities. The ideal result of the calculation is a result in the range from 1 to 2. Going beyond this range to a greater extent will indicate an imbalance in asset management, in the opposite direction – absence of profit or the presence of losses.

Also, an important factor is portfolio diversification, which is often recommended for novice investors. A variety of assets allows reducing the overall risk of investments, since losses on one type of asset can be compensated by profits on others. There are several types of diversification: according to the type of assets (investment in different investment instruments), by country, by economic sectors.

Finally, fundamental and technical analyses also have a significant impact on investment risk assessment. Analysis of market trends, financial condition of companies and macroeconomic indicators allows investors making reasonable decisions and managing risks more effectively.

As already mentioned above, geopolitical situation is another factor that most strongly influences the amount of investment risk. Global instability, political conflicts, military actions or changes in legislation have a great impact on the market and investment opportunities, due to the significant dependence of the investment sector on them. Investors should consider these risks to adapt strategy depending on the current environment.

Perhaps the most volatile aspect in the investment risk assessment is the human factor and market psychology. Emotions can significantly influence the decisions and behavior of market participants.

Finally, an important factor in investment risk assessment is the level of financial literacy. Having sufficient knowledge about financial markets, investment instruments and strategies allows making more reasonable decisions and effectively managing risks. Education, self-education and consultation with experts can significantly improve financial literacy and help investors achieve successful results in the market.

As for considering the risk management plan in general, it comes to defining the following actions:

1) Analysis of risks of the previous period, where the frequency and probability of occurrence of investment risks, as well as their mathematical expectation, are important elements.
2) Analysis of macro- and microeconomic trends, extrapolation of their development
3) Assessment of the impact of possible investment risks during project implementation.
4) Analysis of project flexibility under the influence of external effects

Investment risks, by their nature, represent potential threats and possible losses that may arise when investing capital in order to make a profit. The classification of investment risks includes financial, market, operational, political and other types of risks, each of which requires special attention and analysis when making investment decisions. It is important to remember that risk management plays a key role in achieving successful investment results, so it is necessary to carefully study and analyze all aspects of risk before making investment decisions.

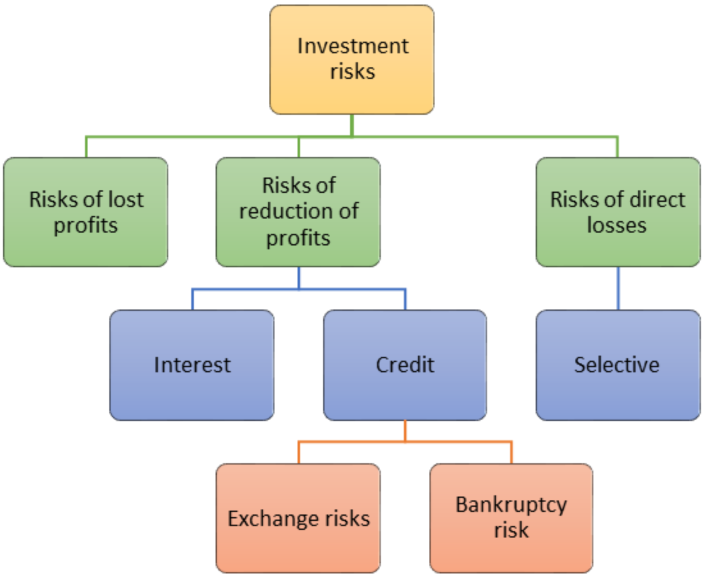

Figure 1: *Classification of investment risks*

The first level of classification is represented by three main risks: the risk of lost profits (the risk of indirect (incidental) financial damage as a result of activities), reduction of profits and direct losses (Fig. 1). The second level arises as a result of a decrease in interest and dividends and is divided into interest and credit risks. Selective risks are the risks of the wrong choice of type of investment.

Since we have examined the basic classification of investment risks, let`s consider in more detail the methods by which we can determine, in fact, the very amount of risk associated with investment activities (Fig. 2).

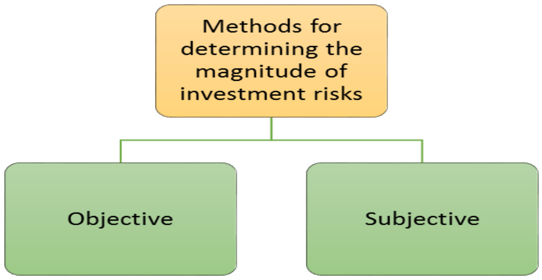

Figure 2: *Methods for determining the magnitude of investment risks*

Objective methods for determining the magnitude of investment risks are based on the collection, processing and analysis of statistical indicators, while subjective methods are based precisely on personal experience and the assessment of experts, the opinion of other specialists. The first ones are applied in case of a representative statistical sample of risks in a certain structure of investment activities. Almost always, in objective methods of determination, probability theory and game theory are used, based on which the mathematical expectation of the occurrence of a necessary event is represented by the product of the absolute value of this event and the probability of its occurrence.

Investment risk assessment is based on two main criteria: the average mathematical expectation M(X) and the fluctuation of the possible result (σ), where

$$\mathrm{M(X)} = \sum_{i=1}^{n} x_i p_i \tag{2}$$

Average mathematical expectation is the expected average profitability or loss from an investment, which is calculated as the product of the probability of an event occurring (p) and the magnitude of that event (x). This criterion allows investors to assess how profitable or risky an investment is in the long term.

Fluctuation or volatility shows the degree of the deviation results around the average expected value. It is calculated as the product of the quotient 1 and the number of observations reduced by 1 and the sum of the squared difference between the arithmetic mean and the price change.

$$\sigma = \frac{1}{n-1}\sum_{i-1}^{n}(m - x_i)^2 \tag{3}$$

The higher the volatility of an investment, the greater the chance of both high profits and significant losses. Therefore, to fully assess the risk of an investment, fluctuations of the possible result must also be taken into account.

One of the most important tasks here is to find a balance between a high mathematical expectation of profitability and an acceptable level of volatility, which will not only maximize potential profits, but also minimize possible losses.

In addition to these two factors, for a more accurate assessment, it is also necessary to consider the correlation between different assets, which shows how strongly they move together, thus allowing to apply a diversification method and reduce the overall risk. For example, if assets are positively correlated, then losses on one asset may be partially compensated by gains on another asset.

Another important aspect of investment risk management is understanding the concept of statistical probability. Besides average expected value and fluctuations, investors should consider the possibility of occurrence of different investment results. This will help them determine not only expected profits, but also potential losses under various scenarios.

Finally, successful portfolio management requires a deep understanding of all aspects of risk, including average mathematical expectation, volatility, correlation and probability. Careful analysis of these factors will help investors make reasonable decisions, optimize their investments and achieve their financial goals in the long term.

So, for example, an investor is considering purchasing shares of Company Z. The average mathematical expectation of this investment is 10% per annum, based on the analysis of historical data and the current situation in the industry. However, the volatility of Company Z shares is assessed as high, with possible fluctuations in profitability from -20% to +30% throughout the year.

Thus, the investment risk for this investment is average, since the average mathematical expectation is 10%, but the volatility is quite high, which increases the chances of both high profits and significant losses. An investor should carefully consider the pros and cons before deciding to purchase shares of Company Z.

Let's consider another example. We have two investment portfolios A and B. A: M(A)=10%, σ=20%, M(B)=5%, σ=10%.

Basing on the data, we can draw the following conclusions: the amount of investment risk for portfolio A is higher than for portfolio B. This is due to the higher volatility of portfolio A, that increases the chances of receiving both high profits and significant losses.

Thus, when assessing investment risk, it is important to consider not only the average mathematical expectation, but also fluctuations of the possible result to make a reasonable decision on choosing an investment portfolio.

In the economic literature there are three main investment strategies to which an investor can resort. All of them are distributed mainly according to the risk level and the type of assets used.

1) Conservative investment strategy (use of the most reliable instruments, such as deposits, government bonds, Eurobonds, stable currencies and precious metals, i.e. those ones, that will not lead to an absolute loss of profit in case of negative external effects). David Rubenstein said, "Persist – don't take no for an answer. If you're happy to sit at your desk and not take any risk, you'll be sitting at your desk for the next 20 years."

2) Balanced strategy (use of reliable assets and speculative instruments; the principle of diversification, which we discussed earlier, is quite often applied here). Ray Dalio said: "More than anything else, what differentiates people who live up to their potential from those who don't is a willingness to look at themselves and others objectively". In our opinion, it is this quote that defines the main task when applied.

3) Speculative or investment strategy (it includes a larger part of risky instruments). The investor is exposed to maximum risk using it. The most appropriate statement here is John C. Bogle's quote: "If you have trouble imagining a 20% loss in the stock market, you shouldn't be in stocks".

Let's consider an example: Olga saved up 100 000 rubles from her first job. She understands that money lying idle is most susceptible to inflation. She decides to invest her funds, creates a personal account in a bank for investing, and now she faces question of where to start from, where to invest them. She has two options to consider:

1) Investment in shares of Company A: the cost of 1 share is 100 rubles (i.e. Olga can purchase 1000 units of shares), the probability of success calculated by experts, is 50% (which is quite risky), the estimated possible profit is 150% (cost for 1 share will increase from 100 rubles to 150). Thus, in case of success, Olga's profit will be 50 000 rubles.

2) Investment in bonds of Company B. In this case, Olga's guaranteed profit will be 10 000.

The risk analysis shows that Company A shares are a riskier option since the probability of success is only 50% and the possible profit could be much higher or lower. While bonds of company B are a more reliable option, as they guarantee a fixed income.

And if we consider the option specifically for a beginner, then it is better for Olga to choose the second option, as the least exposed to risk.

IV. Conclusion

Thus, investment risk assessment is a complex and many-sided process that requires considering many factors, ranging from the degree of market volatility to the financial literacy and emotional stability of the investor. The ability to analyze emerging trends and manage these factors helps to minimize risks and increase one`s chances of achieving the desired results.

The famous economist John Keynes, in his work "The General Theory of Employment, Interest and Money," wrote "The game of professional investment is intolerably boring and over-exacting to anyone who is entirely exempt from the gambling instinct; whilst he who has it must pay to this propensity the appropriate toll". His quote quite clearly describes human activity in the field of investment.

GREENHOUSE GAS ANALYSIS AT THE CARBON TEST SITE OF THE CHECHEN REPUBLIC: MONITORING METHODS AND RESULTS

Aina Vagapova, Luiza Mukaeva, Nadir Gadzhiev

•

Kadyrov Chechen State University, RUSSIA
aina.vagapowa@yndex.ru

Abstract

The article presents the analysis of greenhouse gases at the carbon test site of the Chechen Republic, which serves as an important platform for research in the field of climate change and ecosystem management. The main focus is on the methods for monitoring carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) levels used to assess the carbon balance in various ecosystems of the test site, such as mountain, forest and steppe. The work considers both traditional methods, such as gas analyzers and meteorological stations, and modern technologies, including drones and remote sensors. The evaluation of the obtained data allowed us to identify the key sources of greenhouse gas emissions and determine their impact on the local and global climate. The results showed significant variations in greenhouse gas levels depending on the season, ecosystem type and land management practices. The article also discusses practical recommendations for optimizing monitoring methods for more accurate and effective accounting of carbon flows, as well as the significance of the obtained data for the development of climate change mitigation strategies in the Chechen Republic. The results of the study can serve as a basis for further research in the field of carbon cycle and sustainable management of ecosystems in the context of climate change.

Keywords: carbon polygons, local ecosystems, carbon flows, biodiversity, carbon management, monitoring, research, greenhouse gases

I. Introduction

There are two types of greenhouse effect: natural and enhanced. The natural greenhouse effect is caused by naturally occurring greenhouse gases and is critical to life on Earth. Without this effect, the average surface temperature of the planet would be about 33°C cooler. The enhanced greenhouse effect is due to the additional radiative forcing caused by increased greenhouse gas (GHG) concentrations caused by human activity.

The main greenhouse gases whose concentrations are increasing in the atmosphere are carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), hydrochlorofluorocarbons (HCFCs), and hydrofluorocarbons (HFCs). Due to the long lifetime of these main greenhouse gases, they accumulate in the atmosphere.

Emissions from human activities are causing an enhanced greenhouse effect and climate change. The planet is currently warming faster than at any time in recorded history.

Changes in the chemical composition of the atmosphere lead to changes in weather conditions and disruption of the natural balance, which creates enormous risks for humans and all living beings on Earth.

Atmospheric levels of three major greenhouse gases – carbon dioxide, methane and nitrous oxide – have reached new records, according to the World Meteorological Organization (WMO) Greenhouse Gas Report 2021.

In 2021, atmospheric carbon dioxide levels were 149% of pre-industrial levels, mostly due to emissions from burning fossil fuels and cement production. About half of the CO2 emitted by human activity remains in the atmosphere, while the other half is absorbed by land and oceans, which act as "sinks" — systems that can absorb greenhouse gases. The balance between sources and sinks changes annually due to natural variability.

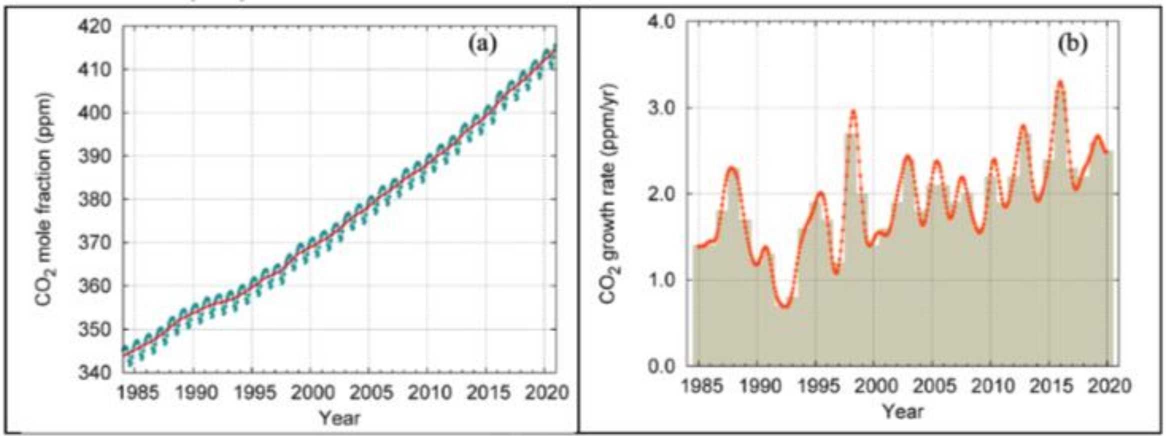

Figure 1: *Globally averaged atmospheric CO2 mole fraction (left) and growth rate (right), 1984-2020.*

As future greenhouse gas emissions increase, land ecosystems and oceans become less effective at absorbing CO2 and acting as a buffer against rising temperatures, which could lead to additional warming of the Earth's atmosphere.

Methane (CH4) accounts for about 16% of the warming effect of long-lived greenhouse gases and remains in the atmosphere for about a decade. 40% of methane in the atmosphere comes from natural sources such as wetlands, while human activities such as rice farming and biomass burning account for the remaining 60%.

Nitrous oxide (N2O) is a potent greenhouse gas and ozone-depleting substance. It is responsible for about 7% of warming caused by long-lived greenhouse gases. Human-related sources, such as fertilizer use and biomass burning, account for about 40% of its presence in the atmosphere.

II. Methods

Concentrations of carbon dioxide (CO2), the most important greenhouse gas, reached 413.2 parts per million in 2020, 149% of pre-industrial levels. Methane (CH4) is 262% and nitrous oxide (N2O) is 123% of the levels that existed in 1750, when human activity began to upset the Earth's natural balance. The economic downturn caused by COVID-19 has not had a noticeable impact on atmospheric greenhouse gas levels and growth rates, although there has been a temporary decline in new emissions.

With continued emissions, global temperatures will continue to rise. Given the long lifetime of CO2, the temperature levels already recorded will persist for several decades even if emissions are rapidly reduced to zero. This, along with rising temperatures, will lead to more frequent extreme weather events, including intense heat and rain, melting ice, rising sea levels, and ocean acidification, with far-reaching socioeconomic consequences.

About half of the CO2 emitted by human activity remains in the atmosphere, while the other half is absorbed by oceans and land ecosystems. The report raises the possibility that the ability of land and ocean ecosystems to act as "sinks" may decline in the future, reducing their ability to absorb carbon dioxide and offset more severe temperature increases.

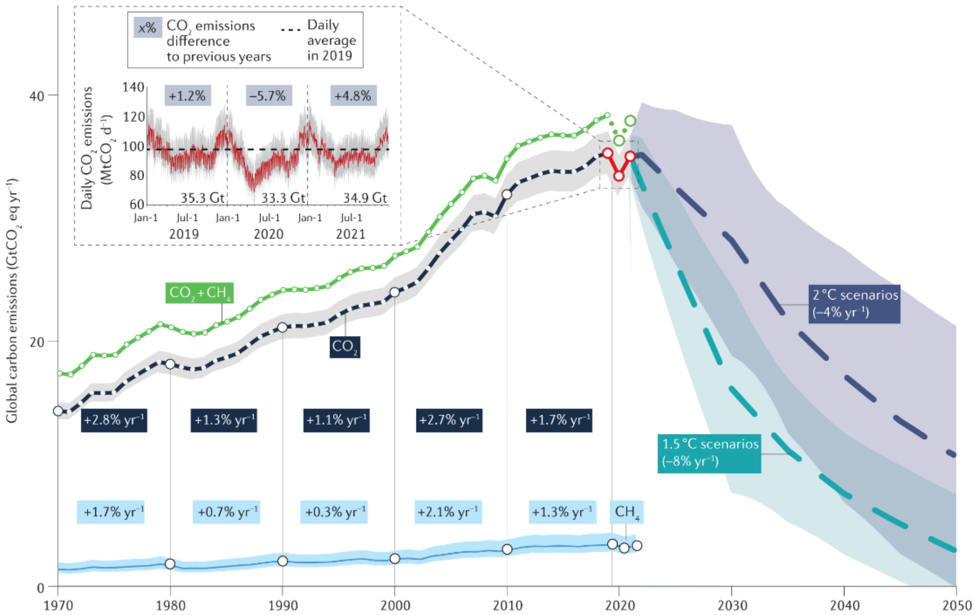

Figure 2: *Global CO_2 and CH_4 emission trends*

Global CO $_2$ emissions have exhibited a rapid increase (Fig. 2). However, embedded within this long-term trend are interannual fluctuations arising from global energy, finance and health crises. For example, during 2020, global lockdowns owing to the COVID-19 pandemic temporarily reduced CO_2 emissions [1 , 2] . The Carbon Monitor program [1,3] — which provides near-real-time daily global CO $_2$ emissions from power generation (29 countries), industry (73 countries), road transportation (406 cities), aviation and maritime transportation, and commercial and residential sectors (206 countries) - offers an opportunity to track the evolution of these CO $_2$ emissions, and in doing so, assess remaining carbon budgets and progress in reaching the Paris Agreement. Here, we document the status of CO $_2$ and fossil CH $_4$ emissions for 2021, revealing a rebound from COVID-related 2020 reductions and a corresponding decrease in the remaining CO $_2$ budget.

According to the report, from 1990 to 2020, radiation exposure— warming effect on our climate — long-lived greenhouse gases increased by 47%, with CO2 accounting for about 80% of that increase. The data is based on monitoring by the WMO's Global Atmosphere Monitoring network. The Greenhouse Gas Bulletin provides a clear scientific message for climate negotiators at COP26. "At the current rate of increase in greenhouse gas concentrations, we will see temperature increases by the end of this century that significantly exceed the Paris Agreement goals of limiting the temperature increase to 1.5 to 2 degrees Celsius above pre-industrial levels," said WMO Secretary-General Professor Petteri . Taalas : "We are on the wrong path."

"The amount of CO2 in the atmosphere passed the 400 parts per million mark in 2015. And just five years later it exceeded 413 ppm. This is not just a chemical formula and numbers on a graph. It has serious negative consequences for our daily lives and well-being, for the state of our planet and the future of our children and grandchildren," added Professor Taalas .

"Carbon dioxide stays in the atmosphere for centuries, and in the oceans even longer. The last time the Earth experienced similar concentrations of CO2 was 3-5 million years ago, when the temperature was 2-3°C higher and sea levels were 10-20 meters higher than now. However, there were not 7.8 billion people on the planet then ," said Professor Taalas .

"Many countries are now setting carbon neutrality targets, and we hope that COP26 will see a sharp increase in commitments. We need to translate our commitments into actions that impact the gases that cause climate change. We need to rethink our industrial, energy and transport systems, as well as our way of life."

III. Results

Carbon landfills play an important role in combating climate change and sustainable management of natural resources. significance Can highlight in several key aspects :

1. **Carbon Balance Monitoring**: Carbon polygons serve as sites for scientific research into the carbon cycle. They monitor greenhouse gas concentrations to assess the level of carbon uptake by ecosystems and the impact of human activity on climate.
2. **Technology development and testing**: Carbon polygons develop and test new technologies and methods to reduce greenhouse gas emissions and increase carbon sequestration. This includes agroforestry practices, rotational grazing, and other sustainable agricultural approaches.
3. **Biodiversity conservation**: Carbon landfills help preserve natural ecosystems and biodiversity. They create conditions for the restoration of degraded lands and support the sustainability of ecosystems, which is important for combating climate change.
4. **Education and Outreach**: These sites also serve an educational function, providing opportunities to study ecology, climate and sustainable development. They serve as a place for learning and sharing experiences among scientists, students and local communities.
5. **Stimulating sustainable development**: Carbon landfills contribute to the development of local sustainable development strategies that can be adapted to specific regional conditions. This includes the creation of jobs in environmental protection and sustainable farming.
6. **Global collaboration**: Carbon polygons facilitate international collaboration on climate change research. They can serve as platforms for sharing knowledge and best practices between countries and research institutions.

Carbon landfills are thus an important tool in the fight against climate change, providing both scientific data and practical solutions to improve the carbon balance and conserve natural resources.

Carbon polygons play a key role in understanding and managing greenhouse gases and combating climate change. They are unique research sites where the carbon balance and concentrations of greenhouse gases such as carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) are monitored. This data helps to assess the impact of human activity on climate and identify sources and sinks of carbon.

Carbon landfills also develop and test new technologies and methods to reduce greenhouse gas emissions and increase carbon sequestration. This can include sustainable agricultural practices such as rotational grazing and agroforestry , which help conserve biodiversity and restore degraded land.

Simplified scheme showing greenhouse gases (GHG) and their effects on plants. GHG (H_2O vapor, clouds, CO_2, CH_4, N_2O, and NO) have both natural and anthropogenic origin, contributing to greenhouse effect. Short-term effects of GHG increase is mainly CO_2 rise, that activates photosynthesis (PS) and inhibits stomatal opening (SO). Long-term effects of GHG increase are extreme climate changes such as floods, droughts, heat. All of them induce the generation of reactive oxygen species (ROS) and oxidative stress in plants. Nitric oxide (NO) could alleviate oxidative stress by scavenging ROS and/or regulating the antioxidant system (AS). GHG and volatile organic compounds (VOC) react in the presence of sunlight (E#) to give tropospheric O_3. Although tropospheric O_3 is prejudicial for life, stratospheric O_3 is beneficial, because filters harmful UV-B radiation. The size of arrows are representative of the GHG concentration.

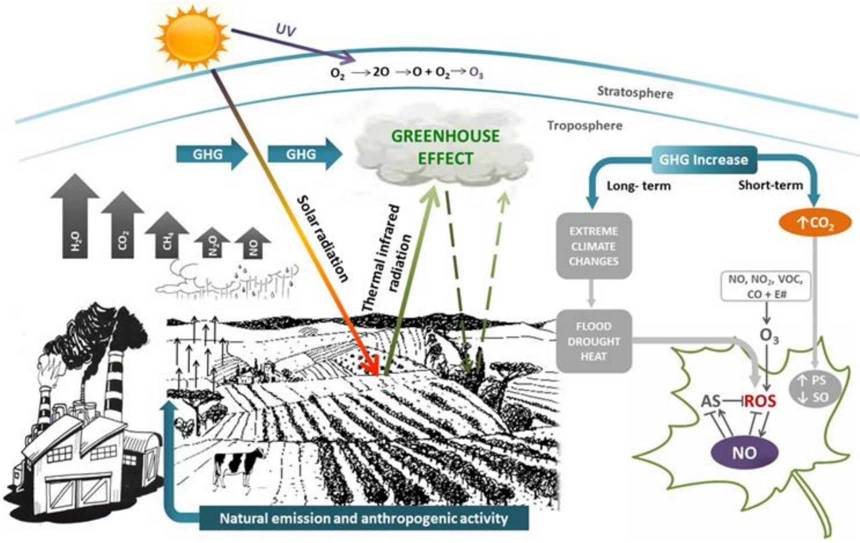

Figure 3: *Greenhouse gases*

The educational function of carbon polygons is also important: they provide an opportunity for learning and exchange of experience among scientists, students and local communities. This contributes to the development of local sustainable development strategies that are adapted to the specific conditions of the region and creates jobs in the field of environmental protection.

In addition, carbon polygons stimulate global cooperation in climate change research by serving as platforms for the exchange of knowledge and best practices between countries and scientific institutions. Carbon polygons are therefore an important tool not only for greenhouse gas research and monitoring, but also for developing practical solutions aimed at improving the carbon balance and preserving natural resources.

IV. Discussion

WayCarbon carbon testing ground in the Chechen Republic is a unique scientific platform designed for research in the field of climate change and ecosystem management. It was created to monitor and analyze greenhouse gas levels, as well as to develop and implement technologies aimed at reducing carbon emissions and increasing carbon absorption.

Main characteristics of the WayCarbon carbon polygon :

1. Scientific Research: WayCarbon conducts detailed studies of the carbon cycle, including monitoring atmospheric concentrations of carbon dioxide (CO2), methane (CH4), and nitrous oxide (N2O). Scientists use a variety of monitoring methods, including weather stations, drones, and sensors, to collect data on carbon emissions and uptake.
2. Ecosystem diversity: The site is located in a variety of landscape types, including steppes and subalpine meadows, allowing for research in a variety of ecosystems and the assessment of their carbon sequestration capacity. Each of these zones has its own characteristics and the research conducted in them.
3. Sustainable Agriculture: The carbon site is home to a regenerative livestock project that includes rotational grazing. This helps maintain biodiversity, restore ecosystems, and increase carbon sequestration, as healthy pastures are better able to absorb CO2.

4. Educational function: WayCarbon also serves as a platform for education and awareness-raising among local communities and students. Participation in research and educational programs helps to shape the next generation of specialists in the field of ecology and sustainable development.

5. Global collaboration: The site actively collaborates with international scientific organizations and universities, facilitating the exchange of knowledge and best practices in the field of climate change research.

6. Socio-economic aspects: The WayCarbon carbon landfill creates new jobs and contributes to the development of the local economy through sustainable management of natural resources and the implementation of environmentally friendly technologies.

WayCarbon carbon polygon in the Chechen Republic is an important tool for combating climate change, providing essential data for monitoring greenhouse gases and developing practical solutions. Its unique scientific base and focus on sustainable development help preserve ecosystems and shape a future focused on environmental protection and social well-being.

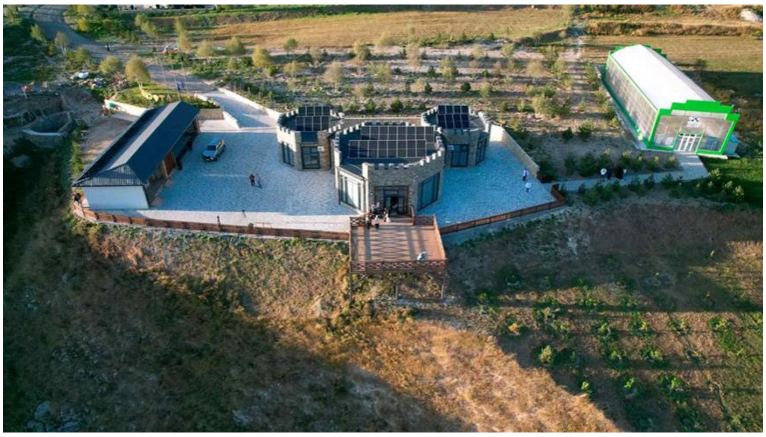

Figure 3: *Carbon Polygon of Kadyrov Chechen State University*

Another way to achieve carbon neutrality is to create conditions for the absorption of carbon dioxide (CO2), which helps offset carbon emissions. This can be done, for example, by planting grasses and trees with high carbon sequestration potential.

What is carbon sequestration? It is the process of absorbing carbon, in this case CO2. The site actively monitors emissions, i.e. the amount of carbon dioxide released from the soil, and the rate at which it is absorbed by plants. The goal is to achieve carbon neutrality, which means zero emissions versus carbon sequestration.

Paulownia, a tree known for its high carbon sequestration potential, was chosen as one of the recommended plant species. In addition, poplar trees provided by the Voronezh Forestry University are also planted at the landfill. Both of these trees are characterized by fast growth, which makes them suitable for carbon absorption projects.

There are plans to introduce other native crops that will also contribute to carbon sequestration. According to forecasts, the carbon farm area will reach 30 hectares by the end of the year. This will significantly increase the volume of carbon dioxide absorption and will contribute to achieving carbon neutrality at the landfill.

At the carbon polygon in the mountains, you will be shown greenhouses where paulownia and poplar trees are grown. These plants have a high potential for absorbing carbon dioxide, which makes them important for projects to improve the carbon balance in the region.

In the laboratory of the engineering center, you will be able to see young seedlings in test tubes. Paulownia, known as one of the most effective trees in terms of carbon sequestration, undergoes a special adaptation process to successfully take root in mountain conditions. First, the seedlings are placed in laboratory test tubes, where they develop in a controlled environment. Then they are transplanted into pots, where they continue to grow and prepare for more difficult conditions. Only then do the young trees go to the greenhouses of the carbon polygon, where they receive the necessary care and attention.

Figure 4: *Planting Paulownia*

The experts at the site will provide detailed information on all stages of growing trees with high sequestration potential. In addition, scientists conduct research and study the sequestration potential of other plants, such as mulberry, willow, linden and ash. This research helps to understand which plant species are most effective in absorbing carbon dioxide in different climates and which of them can successfully grow in mountainous areas. Thus, the carbon polygon not only contributes to the fight against climate change, but also develops scientific knowledge about the vegetation that can help in this process.

The WayCarbon carbon polygon and the A.A. Kadyrov Chechen State University play an important role in achieving carbon neutrality in the Chechen Republic. Thanks to the work carried out, the university territory has already achieved carbon neutrality, which is a significant achievement for the region. At present, it is planned to formalize the status of the first climate-neutral Russian university in the Institute of Global Climate and Ecology. The absence of large-scale production in the republic is an important factor contributing to the implementation of environmental initiatives, since it helps to avoid significant greenhouse gas emissions.

The university's expert council of professors believes that the region is likely to be carbon neutral, but evidence needs to be provided to confirm this. The initiative is actively building evidence bases to assess the university's impact on the environment. Factors such as emissions from transport, energy consumption, and the implementation of climate projects aimed at absorbing CO2 are taken into account.

WayCarbon carbon landfill is planted with plants with high carbon sequestration potential, such as paulownia and poplar. These trees grow quickly and significantly contribute to the absorption of CO2. By the end of the year, the carbon farm is planned to be expanded to 30 hectares, which will help increase the volume of carbon absorption and bring the university closer to carbon neutrality. If the results of the projects confirm a zero or negative carbon impact, CSU will be able to officially secure its status as a carbon neutral university. This will be a significant contribution to efforts to combat climate change both at the regional and national level.

Acknowledgments

The work was carried out within the framework of the state assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 075-03-2021-074/4).

Abstract

Digital and electronic transactions enable to facilitate e–commerce and, based on the use of a green economy, eliminate obstacles to environmental pollution.
The study shows that there are the leaders of the countries which use the institutional and legal norms of the "green economy" in the process of electronic agreements, such as Germany, Great Britain, Hong Kong, Singapore, while at the legislative level these countries determine the norms that regulate digital signature, the use of asymmetric cryptosystem technology, two–factor authentication, storing information in the form of electronic records, while the potential for digitalization is more typical for the finance and insurance industry.
Is important to use legal instruments of using the electronic transactions in the terms of the greening process and the development of state policy at the national and territorial levels. Digital technology and ecology are proved to be two cross–cutting issues that relate to public actions. The participation of all stakeholders in public policy development, transparency and accountability are of great importance.

Keywords*:* digitalization, digital transactions, electronic transactions, ecosystem, digital signature, digital transformation

I. Introduction

Ensuring the use of this system is predetermined by a long–term impact on the development and creation of a competitive digital economic environment, a positive impact on the efficiency and transparency of agreements (Abramova et al., 2023), (Zverkova et al., 2023).

So, the following foreign scientists considered in the works (Davitadze et al., 2023). The Growth and Development of E–Commerce. (Gorbacheva et al., 2021), Harmonisation of the rules on electronic commerce and Serbian law. The Digital Currency Challenge for the Regulatory Regime.

II. Literature Review

The economic literature analyzes various scientific issues of using digital transactions, identifies theoretical and methodological approaches related to green technologies. Among the scientists who have made a significant contribution to these studies are: who focuses on innovations and knowledge which have an impact on the development of economy digitalization.

Cartwright study agreements, conclusion of contracts, release of liability and unfair conditions, deals with the characteristics of an offer or acceptance, the identification of the moment of concluding an agreement and risks.

Elliot focus on the conclusion of an agreement after the proposal is accepted without further negotiations, to the interconnection of the digital economy, the modernization of relations between a human and the environment, the transformation of the business model, focuses on the state regulation of e–commerce and tools for the formation of a single Eurasian economic space, etc.

III. Methods

The general scientific and special methods, such as deduction and induction, statistical analysis were used to solve the set goals. A two–part methodology was used in the study on digital transactions and the impact on a green economy. Firstly, a systematic approach was applied in a general form, when digital transactions were considered taking into account feedback, the impact on the ecosystem, etc.

IV. Results

In addition to a wide range of problems, from collecting detailed digital information online to processing data, it is important to focus on the improvement of ecosystems condition.

Table 1*: Leaders of countries using institutional and legal norms of the "green economy": electronic transactions and digital signatures*

Countries	Name of law	Key features and peculiarities
Leader in cryptography		
1. Great Britain (leader in cryptography)	Electronic Transactions Law	1.1. Supports the use of asymmetric cryptosystem technology 1.2. Regulates the provision of cryptographic services 1.3. Defines and provides confirmation, legal status of an electronic signature
leader in digital transactions, processes and the creation of a paperless economy		
2. Germany (leader in digital transactions, processes and the creation of a paperless economy)	Law on Digital Signature	2.1. Use of electronic signiture: SES–*standard electronic signiture*; QES – *qualified electronic signature*; AES – *authentic electronic signature*. 2.2. Most agreements only require a simple electronic signature 2.3. *Electronic signatures including seals, time stamps, delivery service registrations and certificates to authenticate websites* are used
Leader in two–factor authentication		
3. Singapore (leader in two–factor authentication)	Electronic Transactions Law	3.1. Electronic records can be used to express an offer or acceptance in conclusion of a contract 3.2. A method to identify the person who signs two–factor authentication is used

		3.3. The availability of an electronic signature panel for capturing signatures 3.4. Use of distributed ledger technology, smart contracts and biometrics
Leader in the preservation and recognition of electronic records		
4. Hong Kong (China) (leader in the preservation and recognition of electronic records)	Electronic Transactions Law	4.1. Provides a legal basis for the recognition of electronic records and signatures, giving them the same legal status as on paper 4.2. Signature requirement, according to the law, can be done by any form of electronic signature and submission or storage of information in the form of electronic records
5. Saudi Arabia	Electronic Transactions Law	5.1 Electronic transactions: transactions which are carried out by electronic means. 5.2 Transactions: a procedure or group of procedures that is performed between two or more parties to create obligations for one party or mutual obligations. 5.3 The clauses of the law are applied to transactions in which the parties agree to carry out their transactions by electronic means 5.4 Authentication procedures are considered commercially acceptable if they take into account the commercial terms of the parties to the transaction.
6. Australia	Electronic Transactions Law	6. Duration of electronic transactions For the purposes of Commonwealth law, a transaction is not invalid because it was carried out fully or partially through one or more electronic messages.
7. Canada	Electronic Transactions Law	7. Errors that may occur when working with electronic agents An electronic record created by an individual using an electronic agent of another person's is not valid and unenforceable if the individual has made a material error in the record
8. Singapore	Electronic Transactions Law	8.1 Electronic Transactions Act (ETA) (Cap 88) was first adopted in July 1998 to provide a legal basis for electronic signatures and to give predictability and certainty to contracts concluded electronically. 8.2. In July 2010, the ETA was canceled and re–enacted to ensure the permanent security and use of electronic transactions. 8.3. Commercial Code for Electronic Commerce Transactions: ETA was adopted to create a predictable legal environment for electronic commerce. It clearly defines the rights and obligations of the parties to the transaction.

The analysis of the leading countries which use the institutional and legal norms of «green economy» increasingly shows a significant gap between countries with weak market economy and leading countries (Table 1). Germany is the leader in digital transactions, creating paperless economy. Along with this country, the active participants in this process of electronic agreements are: Great Britain, Singapore, Hong Kong, which are developing a rather effective model of electronic transactions in the terms of using green technologies.

Despite the inequality in the digital economy, the enterprises in the countries have opportunities to get benefit from the digitalization of electronic transactions. Such opportunities can arise from the productive use of global digital platforms.

The present and future shifts and changes, that lead to the need for faster use of digital transactions, can be caused by several reasons, often simultaneously, at the level of customer behavior and expectations, new economic realities, social shifts, ecosystem/industry disruption and (accelerating implementation and innovation) emerging or existing digital technologies.

Wassily Leontief proposed a theory of general equilibrium that can be implemented empirically, and proved that the so–called partial analysis cannot provide a sufficiently broad basis for a fundamental understanding of the structure and functioning of economic systems. He began using the large–scale mechanical computing machine in 1935 and the electronic computing machine in 1943 while compiling the first input–output tables for the American economy. In recent years, he has focused on the analysis of environmental disruption and economic growth, while maintaining an active interest in the broader issues of scientific methodology for social and economic policy, as well as evolutionary and revolutionary changes.

Jean Tirol, French Nobel laureate, noted that "as innovation is deeply rooted, the age of knowledge will open up many opportunities ... universities or highly educated people on their own cannot define the era of innovation, as some of the startups started from humble beginning to succeed). This potential starts to be implemented in the age of information, digital and telecommunication technologies.

Emmanuelle Benicourt, quoting such an authoritative scientist, stated: «information is the basis for the allocation of resources based on the action of the market mechanism».

The electronic transactions in the legislation of some countries of the world are determined primarily by key parameters using any type of modern technical tools, i.e. they represent any act or contract concluded or subject to the partial or full execution by electronic communications using electrical, digital, magnetic, wireless, optical, electromagnetic, or any other equivalent tools.

It must be noted that such types of agreements began to appear to a greater extent due to the development of the Internet and computer technologies. The academician S.Glazyev notes that «ubiquitous computerization and a large–scale expansion of the scope of computer systems have initiated the emergence of the current topic of the digital revolution» (Glazyev, 2020). Due to the strengthening of these trends and the automation process for many industries, this will lead to the creation of new jobs (more than 2 million all over the world) for such professions as analysts, software developers, engineers and other highly qualified experts. However, this will lead to the reduction of 7 million jobs requiring the involvement of mid–level personnel, whose work will be performed by robots in future.

The electronic contracts, that today enterprises exchange and propose the possibility to dynamically, automatically create and apply behaviorally related services, are designed to achieve business goals. In cases when there are many contracts within a particular application, it can be difficult to determine whether the system can reliably perform all of them, but electronic contracts with computer analysis can automate the verification process.

And nowadays, we are becoming the participants of the fourth revolution – the digital one, which led to a large–scale transformation of all sectors of the economy.

The smartphone has become a point for receiving and providing services, a key link for making transactions. At the same time, «the gross value of goods in the cross–border e–commerce market ... will grow by about 25% annually till 2020 ... New 'micro–jobs' platforms, such as Upwork and Freelancer also provide entrepreneurs and enterprises with the ability to sell services online».

The fact that people will become entrepreneurs can significantly reduce the expected unemployment rate due to workplace automation.

Changing to another profession in the framework of paid employment will create preconditions for additional costs, for example, connected with acquiring a new qualification (Fossen & Sorgner, 2018). That is, the part of the employees will gradually be released from their jobs and may become interpreters who will be able to use environmental standards in a new way.

It should be taken into consideration that at the same time many Western and Northern European companies developed their main IT systems in the 1970s and 80s. These systems functioned properly until the last decade. However, in recent years, the IT environment has changed dramatically with the emergence of web communications, network computing and plug–

and–play systems. Having joined the digitization race quite late, the digital competitors are often less attached to such legacy systems because they do not have to discount the large investments of the previous generation. Consequently, it is easier for them to master new technologies, which allows them to jump over intermediate technologies. An example is the banking sector. In Central and Eastern Europe, financial transactions based on the payment cards were made without using checks. Today, the countries of the region can be proud of one of the highest rates of adopting contactless payment in the world. Thus, while digital competitors may find it difficult to compete in the traditional economy, they use them easily in the digital economy.

Potential for automation and digitalization in industry (Figure 1)& Digitalization index (Figure 2).

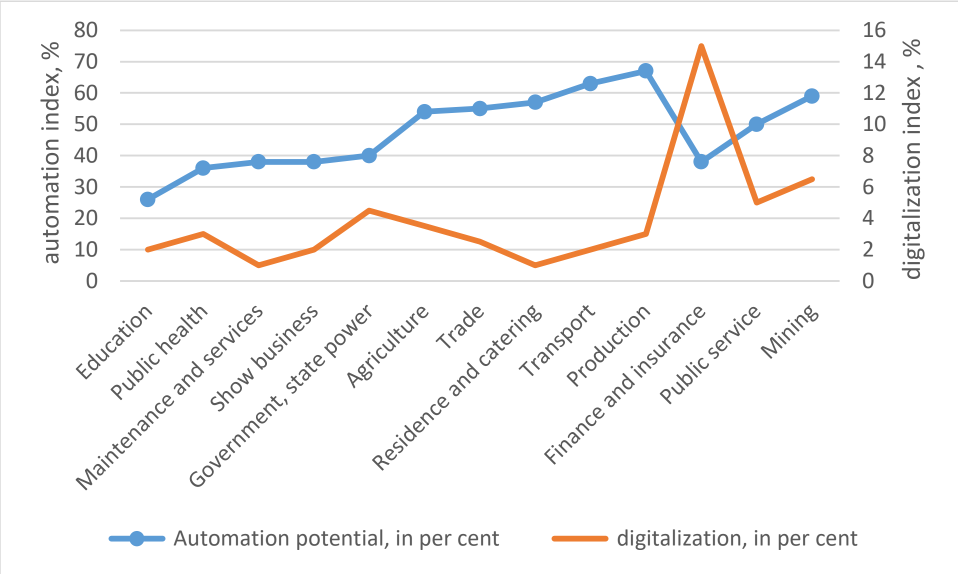

Figure 1: *Potential for automation and digitalization in industry*

Source: it was compiled by the authors based on data, Eurostat; McKinsey Global Institute; McKinsey analysis

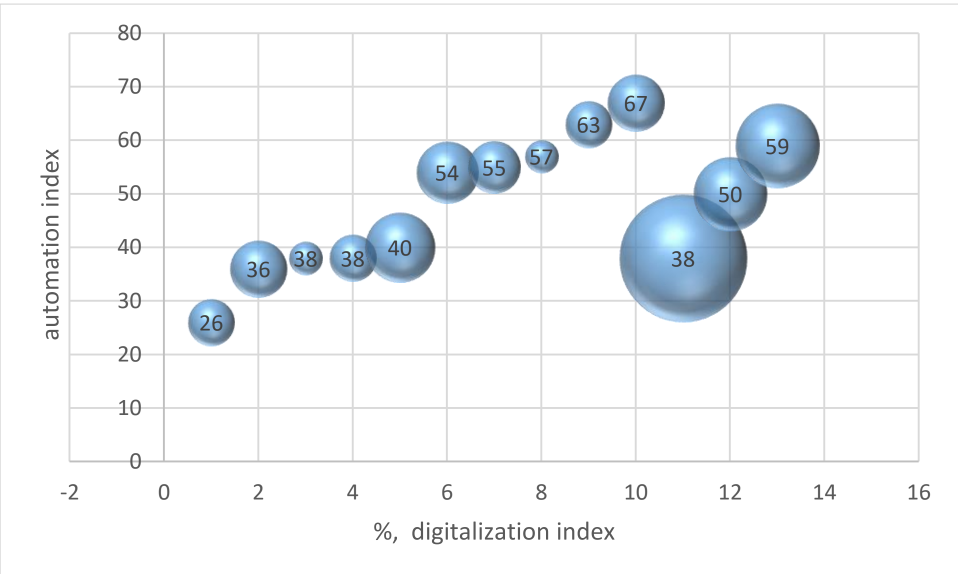

Figure 2: *Digitalization index*

Source: it was compiled by the authors based on data, Eurostat; McKinsey Global Institute; McKinsey analysis

As Figure 2 and Figure 3 shows, the potential for digitalization is more common in the finance and insurance industry than in the education and health sector.

Therefore, e–commerce can be classified according to the criterion of participants in virtual transactions (Table 2).

Table 2: *E–commerce and classification according to the criterion of participants in virtual transactions*

No.	Classification	Meaning
1.	B2G (Business–to–Government)	implies the implementation of transactions between economic entities (legal entities)
2.	B2B (Business–to–Business)	implies the implementation of transactions between economic entities of the market. Technically, such interaction is usually based on specialized open Internet platforms with a standard set of tools and rules. Interactive databases enable not only to provide a large volume of proposals, but also to track the process of order execution. B2B transactions often include organizing wholesale supplies of goods and placing orders at manufacturing enterprises
3.	B2C (Business–to–Consumer)	a type of e-commerce, which implies the transactions between legal entities and individuals. Most often it is retail via Internet. These can be specialized seller portals, electronic trading sites or direct mailings.
4.	C2C (Consumer–to–Consumer)	a type of e-commerce, which implies the transactions between individuals. This is usually trading through electronic bulletin boards (Slando, Avito, etc.) or on electronic trading sites (Molotok, Meshok, eBay, Delcampe, etc.)

Such virtual transactions can be considered as «green technologies, creating hybrid physical–digital solutions, increasing the efficiency of business processes through which eco–innovation is developed, and providing new functional opportunities».

The indicators of green growth in the Republic of Kazakhstan are given in Table 3.

Table 3: *Green Growth Indicators*

		1990	2010	2013	2016
All technologies (total patents)		1039	2384,15	2639,43	2695,71
Selected environment–related technologies		93,08	322,64	278,48	246,92
Environmental management		63,42	145,83	114,25	121,33
Environmental management	Air pollution abatement	15	40,42	36,58	19,5
	Water pollution abatement	34,33	71,17	44,67	50,17
	Waste management	14,08	32,75	33	47,67
	Soil remediation	0	0	0	3
	Environmental monitoring	0	1,5	0	1
Water–related adaptation technologies		8	25,5	30,83	17,5
Water–related adaptation technologies	Demand–side technologies (water conservation)	7	15,5	20	11,5
	Supply–side technologies (water availability)	1	10	10,83	6
Climate change mitigation		52,58	227,31	208,15	169,08
Climate change mitigation	Climate change mitigation in information and communication technologies (ICT)	0	4,17	14,03	6,5
	Climate change mitigation	11,5	128,95	100,95	65,83

The developed regulatory legal acts in the field of electronic transactions in Kazakhstan are presented in Table 4.

Table 4: *Regulatory legal acts in the field of electronic transactions*

№	Name
1	Civil Code of the Republic of Kazakhstan (general part) № 268–XII dated December 27, 1994 (as *amended* on 10.01.2020)
2	Letter of the territorial Tax code No.1839 "Regarding the accounting and taxation of electronic accounting units of the Webmoney payment system, intended for making payments on the Internet"
3	The order of the acting Minister for Investment and Development of the Republic of Kazakhstan No.74 On approval of requirements for the content, maintenance and information filling with electronic information resources of the e–government web–site dated January 26, 2016

Source: developed by the authors

From Table 1 it can be seen that electronic transactions are very relevant in Kazakhstan, in connection with this, various legal documents are being developed related to the regulation of electronic transactions.

Therefore, the interaction between the parties should be focused in electronic transactions. In fact, a satisfactory emulation of the concepts associated with the definition of who are the specific parties involved in the offer and acceptance on the basis of which the transaction is carried out, must be ensured in order to achieve the necessary functional equivalence of the electronic transaction system. Therefore, today it is important to take into consideration the fact that individuals can create automated electronic agents with which the other party interacts when concluding a contract.

Although the potential of Internet for saving material and energy resouces cannot be denied, it is still too early to say about positive impact of the emerging digital economy on the environment. We do not believe that our society has fully reached the stage when our science and engineering are ready to reconcile our economy and our environment in order to bring about a Copernican pivot which is characterized by saving hydrogen fuel, landless agriculture and an industrial ecosystem in which waste virtually disappears. The growth of e–commerce further stimulated business expansion.

However, in the Republic of Kazakhstan it is important to use sufficiently powerful legal tools of using electronic transactions in the terms of the greening process and the development of state policy. Since at the national and territorial levels, the digital technologies and the environment are two cross–cutting issues that relate to public actions.

Digital technologies provide new tools to support these efforts. In addition to participation of citizen, digital technologies also facilitate the increase and interaction of persons who can contribute through their initiatives to the achievement of common environmental goals: citizens and groups, start–ups, large global operators, etc. Digital technologies should also have a profound impact on the content of state environmental policy. They create new tools for actions of government bodies: behavioral incentives, collaborative mobility systems, common work and production spaces, and «zero carbon society» projects.

V. Discussions

A sharp increase in digital technologies is predicted in the world and the Republic of Kazakhstan, and in this case, many enterprises will accept significant changes in the structure of the business model in the terms of digital transactions, taking into account the state of the ecosystem. The enterprises will need new collaborative technologies. At the same time, e–commerce and sales practice will have to adapt to a new digital format of interaction, which is likely to entail a significant change in legislation and programs for the digitalization of the economy (Antonenko, (2021), Archimandritova & Suptelo, (2022), Bunevich & Gorbacheva, (2022), Burykin, (2020), Gavrilova, (2020), Gavrilova & Demjanjuk,(2023), Davydovsky, (2019), Davitadze & Marakov,(2023), Dzyuba, (2021), Kamyshnikov, (2023), Kozunova, (2021), Koryakov, (2016), Koryakov et al., (2016), Kubova et al. ,(2018), Kuksin, (2020), Makovetsky & Rudakov, (2021). Panshin & Serebryakov, (2020), Suptelo & Dolgikh, (2021),Salikhov & Semenov, (2019), Slabospitsky & Slabospitskaya, (2022), Zhiltsov S. et.al.,(2018), Zonn & Orlovsky, (2019), Tebekin, (2023), Tyunyakova, (2017), Zagorov,(2022), Zubets, (2019), Zueva, 2017, Zhuravleva & Shlyakhin, (2018), Gorda, (2022) [1-18].

VI. Conclusion

In the process of development of the digital economy, the electronic transactions must contain electronic records, or data messages, electronic signatures, which are subsequently created, transmitted and stored in electronic form. Taking into account data analysis and forecast, certain types of economic activities will be expanded and have great forecasting potential. There are the leaders of the countries which use the institutional and legal norms of the "green economy" in the process of electronic agreements, while at the legislative level these countries determine the norms that regulate digital signature, the use of asymmetric cryptosystem technology, two–factor authentication, storing information in the form of electronic records, while the potential for digitalization is more typical for the finance and insurance industry. The leaders of the countries that use the institutional and legal norms of the "green economy" in the process of electronic agreements are highlighted, while at the legislative level in these countries the norms are defined that regulate the digital signature, the use of asymmetric cryptosystem technology, two–factor authentication, storing information in the form of electronic records, while the potential for digitalization is more characteristic of the finance and insurance industry.

Abstract

Ecotourism is an important and rapidly growing sector in the tourism industry, offering unique opportunities to mitigate climate risks and enhance the competitiveness of tourism destinations. In the context of global climate change, ecotourism can play a key role in developing sustainable practices that contribute to environmental protection and the socio-economic development of local communities. This paper explores how ecotourism can be a tool for climate change adaptation, reducing negative environmental impacts while improving economic conditions in tourism regions. It focuses on successful examples of ecotourism initiatives that demonstrate how an integrated approach to ecotourism can lead to the creation of resilient ecosystems and economic prosperity. One of the key aspects of ecotourism is its ability to develop sustainable practices, such as the use of renewable energy, resource management, and biodiversity conservation programs. These practices not only reduce the carbon footprint of tourism activities, but also provide long-term economic benefits to local communities through job creation and support for the local economy. The study also examines the involvement of local communities in tourism activities as a way to improve their economic resilience and social well-being. By actively participating in ecotourism projects, local communities can gain access to new sources of income and educational opportunities, which contributes to improving their quality of life. The results show that ecotourism not only mitigates climate risks, but also increases the resilience of local economies to climate change, while providing educational and cultural benefits for tourists. Ecotourism helps to create awareness of the importance of sustainable development among both travelers and local residents, which ultimately contributes to a more harmonious coexistence between humans and nature. Ecotourism is therefore an important aspect in adaptation strategies and development of the tourism industry in the context of a changing climate. Given its potential for creating sustainable development models, this work highlights the need to integrate ecotourism into global and local strategies to combat climate change and improve the competitiveness of tourist destinations.

Keywords: Ecotourism, climate risks, competitiveness, sustainable development, environmental protection, local communities, biodiversity, renewable energy, economic growth

I. Introduction

In recent years, the global tourism industry has gained significant recognition as a vital contributor to economic development, job creation, and cultural exchange. However, this growth is accompanied by pressing challenges, particularly those posed by climate change. The tourism sector is highly sensitive to climate risks, including rising sea levels, extreme weather events, and changes in ecosystems, which threaten the sustainability of popular destinations. As these challenges intensify, there is an urgent need for the tourism industry to adopt innovative strategies that promote resilience and sustainability.

Eco-tourism has emerged as a promising approach to address these challenges, offering a pathway to mitigate climate risks while enhancing the competitiveness of tourism destinations. Defined as responsible travel to natural areas that conserves the environment and improves the well-being of local communities, eco-tourism emphasizes sustainability, education, and community involvement. By focusing on sustainable practices, eco-tourism not only reduces the negative impacts of tourism on the environment but also promotes awareness of ecological issues among tourists and local populations.

The role of eco-tourism in the context of climate change is multifaceted. Firstly, it fosters sustainable development by encouraging practices that protect natural resources and biodiversity. This includes the adoption of renewable energy sources, waste reduction strategies, and conservation efforts that can help mitigate the impacts of climate change. Secondly, eco-tourism contributes to the economic resilience of local communities by creating job opportunities and generating income through sustainable tourism activities. When local communities are actively engaged in eco-tourism initiatives, they are more likely to invest in the conservation of their natural resources, thereby fostering a cycle of sustainability and economic growth.

Moreover, eco-tourism promotes educational opportunities for both tourists and locals. Through immersive experiences in nature, travelers gain a deeper understanding of environmental issues and the importance of conservation. This increased awareness can lead to more responsible travel behaviors and greater advocacy for sustainable practices, both at home and in the destinations they visit.

Despite its potential, eco-tourism also faces challenges, including the need for effective management, the risk of over-tourism in fragile ecosystems, and the necessity for appropriate policies and regulations. Understanding the role of eco-tourism in mitigating climate risks and enhancing competitiveness requires a comprehensive analysis of its economic, environmental, and social dimensions.

This paper aims to explore the role of eco-tourism as a viable solution for addressing climate risks while enhancing the competitiveness of tourism destinations. By examining successful eco-tourism initiatives and their impacts on local communities and ecosystems, this research seeks to provide insights into best practices and strategies that can be implemented across the industry. Ultimately, this analysis will contribute to the broader discourse on sustainable tourism development in the face of climate change, highlighting the importance of eco-tourism in creating a resilient and thriving global tourism economy.

Approaches to strategy development are closely related to the analysis of complex data, which requires the use of a variety of methodological tools. These include logical modeling, inductive and deductive analysis methods, as well as statistical and economic techniques (Fig .1). These tools support the process of systematizing information and forming strong strategic foundations.

It is also important to develop coordination mechanisms and coordinated actions of all participants in the tourism industry. This will ensure a synergistic effect for the effective achievement of common goals. These measures are the foundation for an effective strategy capable of ensuring growth and sustainability both at the national and international levels, strengthening the economic basis of tourism enterprises and the entire sector as a whole.

An analysis of the current trends in the development of the tourism industry reveals a number of important issues that need to be considered when developing strategies for this sector. This involves the need to create a comprehensive regulatory framework that promotes optimal conditions for the operation of tourism and hotel enterprises, taking into account their economic, managerial and administrative contexts. Further, the emphasis is placed on strengthening the role of government regulation with the protection of the interests of all entities in this sphere. In addition, the importance of active participation of public organizations in preserving the basic principles of tourism development and establishing cooperation between government agencies, business representatives, educational and scientific institutions is emphasized.

These findings provide the basis for a strategy of profound change that involves joint efforts by governments and the private sector to carefully examine and respond to the challenges posed by the loss of tourists, stimulate investment and develop programmes that support the growth and strengthening of the sector.

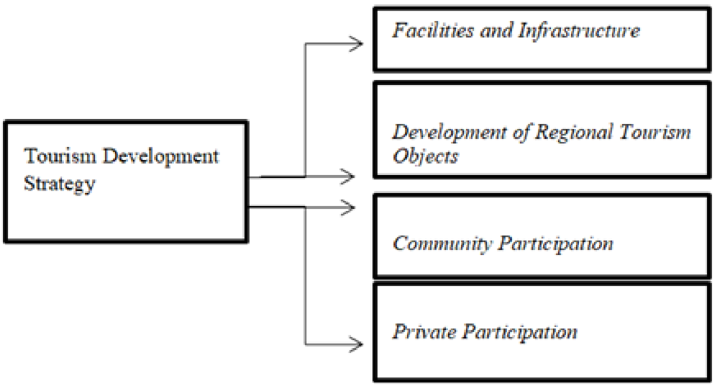

Figure 1: *Tourism Development Strategy*

Particular attention should be paid to the strategy aimed at maintaining stability in an unfavorable economic environment, which uses customer retention measures, including offering additional services, innovation and improving the overall quality of service, which helps to strengthen customer loyalty even in more difficult economic conditions.

On the other hand, the achieved growth strategy is used in situations where the company has limited capacity for innovative development or when the market is close to saturation. Here, we are talking about focusing efforts on optimizing current operations and maintaining the existing sales level by improving and modifying the tours or services offered.

The development of these strategies is based on an arsenal of tools that can solve the tasks set in the context of the current conditions. Such tools include: flexible pricing, service modernization, expansion of partnerships, brand strengthening, marketing and PR campaigns, as well as improving the quality of management and introducing innovations.

The expected results from the implementation of these strategies include, but are not limited to: successful achievement of objectives, increased revenues, enhanced market position, sustainable satisfaction of tourist needs, maximization of return on capital investment and enhanced competitive advantages. This leads to long-term sustainability and prosperity of tourism and hotel enterprises.

II. Methods

Creating a strategy for the eco-tourism industry is a multi-step process, with each step having a significant impact on the final outcome. Research confirms that the approach to strategic planning should be systematic and goal-oriented, with clear priorities and a well-thought-out schedule of specific actions.

At the initial stage – the intellectual stage – the fundamental principles on which the strategy will be built are formed, including a clear mission that unites the common goal, vision of the future and the main functions of the industry. This mission is aimed at increasing the efficiency of the industry and creating conditions for modern competition.

The next step is diagnostics, which involves analyzing external and internal conditions, opportunities and threats in order to consciously approach the formation of long-term and short-term goals. These goals must be detailed into strategic objectives that will serve as beacons in the process of implementing the strategy.

Next comes the analysis of strategic alternatives, which is focused on evaluating and comparing various approaches and development paths in order to select the most appropriate and promising one. The choice of strategy involves weighing all the pros and cons and taking into account the unique aspects of the enterprise, whether these are ultimate goals, management priorities, strategic resources, scale of operations or competitive advantages.

The final stages – implementation of the strategy and its subsequent assessment of its effectiveness – are focused on the practical application of the chosen plan and monitoring of the achieved results. This allows for fairly prompt adjustments to actions in the event of unforeseen changes in the industry or external environment and ensures business flexibility, which is one of the key aspects of a successful strategy in the dynamic tourism industry.

III. Results

The exploration of the role of eco-tourism in mitigating climate risks and enhancing competitiveness yielded several significant findings. These results illuminate the potential of eco-tourism to contribute positively to environmental sustainability, local economic resilience, and social well-being.

1. Economic Benefits of Eco-Tourism

The analysis revealed that eco-tourism initiatives have a notable positive impact on local economies. In regions where eco-tourism has been implemented, there has been a marked increase in job creation and income generation. For instance, case studies from several eco-tourism hotspots, such as Costa Rica and the Galápagos Islands, indicated that eco-tourism contributes significantly to GDP and creates employment opportunities in areas like guiding, hospitality, and conservation management.

Moreover, eco-tourism promotes the diversification of income sources for local communities, reducing their dependency on traditional sectors that may be more vulnerable to climate change, such as agriculture and fisheries. This economic diversification is crucial for enhancing the resilience of communities to climate-related shocks.

2. Environmental Impact and Conservation Efforts

Eco-tourism's focus on sustainability and conservation has led to measurable improvements in environmental management practices. Destinations that adopted eco-tourism practices reported better preservation of natural habitats and biodiversity. For example, protected areas that incorporate eco-tourism have seen increased funding for conservation efforts, resulting in enhanced ecosystem protection and restoration initiatives.

Additionally, eco-tourism promotes the use of renewable energy sources and sustainable practices among local businesses. Surveys conducted among eco-lodges and tour operators indicated a high level of commitment to environmentally friendly practices, including waste reduction, energy efficiency, and responsible sourcing of local materials.

3. Community Engagement and Social Development

The study highlighted the critical role of community engagement in the success of eco-tourism initiatives. Active involvement of local communities in eco-tourism projects fosters a sense of ownership and responsibility toward environmental conservation. Communities that participated in eco-tourism development reported improved social cohesion and enhanced pride in their cultural and natural heritage.

Furthermore, eco-tourism provides educational opportunities for both tourists and local residents. Programs that involve local guides in educating tourists about conservation practices and local ecosystems not only empower communities but also promote sustainable behaviors among visitors. Data indicated that tourists who engaged in educational eco-tourism activities expressed a higher level of environmental awareness and commitment to sustainable practices.

4. Challenges and Barriers to Success

Despite the positive outcomes associated with eco-tourism, several challenges were identified. Issues such as over-tourism in sensitive areas, lack of regulatory frameworks, and inadequate infrastructure can undermine the potential benefits of eco-tourism. In some instances, eco-tourism development has led to environmental degradation when not properly managed.

The findings also indicated that while eco-tourism can enhance competitiveness, its success is highly dependent on effective marketing and branding strategies. Destinations that successfully position themselves as eco-tourism hubs are more likely to attract visitors interested in sustainable travel.

5. Policy Implications and Recommendations

The results underscore the need for supportive policies and frameworks to maximize the benefits of eco-tourism. Governments and stakeholders must work together to establish guidelines that promote sustainable practices, protect sensitive ecosystems, and ensure equitable distribution of economic benefits to local communities.

Investment in infrastructure and capacity-building initiatives is essential for enhancing the effectiveness of eco-tourism programs. Training for local entrepreneurs and stakeholders in sustainable practices, marketing, and visitor management can contribute to the long-term success of eco-tourism initiatives.

The results of this study highlight the vital role that eco-tourism can play in mitigating climate risks while enhancing the competitiveness of tourism destinations. By providing economic opportunities, fostering environmental stewardship, and engaging local communities, eco-tourism emerges as a promising model for sustainable development in the face of climate change. To realize its full potential, however, it is imperative to address the challenges associated with eco-tourism and to implement robust policies that support its growth and sustainability.

When developing a strategy for the tourism industry, the main focus should be on its integration with the socio-economic goals of the state. This includes stimulating the development of technological innovation, attracting investment, ensuring economic stability, and helping to improve the overall level of well-being of citizens.

It is necessary to take into account the geographical location of border areas, because by doing so you create favorable conditions for the tourism industry to flourish thanks to natural advantages and international cooperation.

Improving the quality and diversity of tourism and hotel services is necessary to strengthen the market position and ensure its dynamic development. When planning economic strategies for regions, special attention should be paid to ensuring that the offers created correspond to the demands and expectations of tourists, and that their implementation is aimed at satisfying the real needs of visitors. This will contribute to the creation of conditions not only for successful competition, but also for sustainable socio-economic progress.

IV. Discussion

The findings from this study illustrate the multifaceted role of eco-tourism in mitigating climate risks and enhancing the competitiveness of tourism destinations. As the tourism sector grapples with the challenges posed by climate change, eco-tourism emerges as a viable solution that not only addresses environmental concerns but also supports local economies and communities. This discussion delves into the implications of these findings, highlighting key considerations for stakeholders and suggesting pathways for future development.

1. Integration of Economic and Environmental Goals

The positive economic impacts associated with eco-tourism demonstrate its potential to reconcile economic growth with environmental conservation. By investing in eco-tourism initiatives, stakeholders can create sustainable business models that leverage natural resources while preserving them for future generations. This dual benefit can be particularly crucial in regions where traditional economic activities may be increasingly jeopardized by climate change.

To harness this potential fully, it is essential for policymakers and industry leaders to integrate economic and environmental goals into strategic planning. This might involve creating incentives for businesses that adopt sustainable practices or providing financial support for community-led eco-tourism initiatives. Moreover, fostering partnerships between the public and private sectors can enhance resource mobilization for eco-tourism projects and ensure that they are designed to benefit both the economy and the environment.

2. The Importance of Community Involvement

Community engagement emerged as a pivotal factor for the success of eco-tourism initiatives. The findings suggest that when local communities are actively involved in the planning and implementation of eco-tourism projects, they are more likely to feel a sense of ownership and responsibility for their natural environment. This increased stewardship can lead to more effective conservation efforts and a stronger commitment to sustainable practices.

To strengthen community involvement, stakeholders should prioritize capacity-building initiatives that empower local residents with the skills and knowledge needed to participate in eco-tourism. This includes training in hospitality management, environmental education, and marketing strategies. Such investments can enhance local livelihoods while fostering a culture of sustainability that permeates the community.

3. Addressing Challenges and Risks

Despite the promising outcomes associated with eco-tourism, the study highlighted several challenges that could hinder its effectiveness. Over-tourism remains a significant concern, particularly in ecologically sensitive areas. If not carefully managed, an influx of visitors can lead to habitat degradation, resource depletion, and negative social impacts.

To mitigate these risks, it is essential for eco-tourism destinations to implement robust visitor management strategies. This could involve setting visitor caps, implementing zoning regulations, and promoting off-peak travel. Additionally, developing clear guidelines for eco-tourism practices can help ensure that all stakeholders adhere to sustainable principles. Collaboration between governments, non-governmental organizations, and the private sector is crucial for creating these guidelines and monitoring compliance.

4. Leveraging Technology and Innovation

The integration of technology in eco-tourism presents an opportunity to enhance both visitor experiences and environmental management. Digital platforms can facilitate better communication between tourists and local communities, enabling more informed travel decisions that prioritize sustainability. Additionally, technology can be used to monitor environmental impacts in real-time, allowing for swift responses to any emerging issues.

Innovative practices, such as virtual reality experiences that promote environmental education or apps that track carbon footprints during travel, can also enhance the eco-tourism experience. By leveraging technology, eco-tourism can appeal to a growing demographic of environmentally conscious travelers seeking meaningful and sustainable travel experiences.

5. Future Research Directions

While this study provides valuable insights into the role of eco-tourism in addressing climate risks, further research is warranted to deepen understanding of its long-term impacts. Future studies could investigate the effectiveness of specific eco-tourism initiatives across different geographic regions and cultural contexts. Additionally, exploring the interplay between eco-tourism and other sustainable development goals could yield insights into how this sector can contribute to broader global efforts.

Another area for future research could focus on the social dynamics within communities engaged in eco-tourism. Understanding how eco-tourism affects social structures, gender roles, and cultural practices can inform more inclusive and equitable approaches to sustainable tourism development.

In summary, the discussion highlights the significant potential of eco-tourism to address climate risks while enhancing the competitiveness of tourism destinations. By aligning economic, environmental, and social objectives, stakeholders can create sustainable tourism models that benefit local communities and preserve natural resources. However, realizing this potential requires proactive management, community engagement, and a commitment to continuous improvement. As the tourism sector navigates the challenges of climate change, eco-tourism stands out as a promising pathway toward a more sustainable and resilient future.

In summary, the discussion highlights the significant potential of eco-tourism to address climate risks while enhancing the competitiveness of tourism destinations. By aligning economic, environmental, and social objectives, stakeholders can create sustainable tourism models that benefit local communities and preserve natural resources. However, realizing this potential requires proactive management, community engagement, and a commitment to continuous improvement. As the tourism sector navigates the challenges of climate change, eco-tourism stands out as a promising pathway toward a more sustainable and resilient future.

In the last twenty years, tourism has emerged as a leading sector stimulating growth in competitiveness in the context of expanded reproduction within the capitalist economy. With advances in tourism infrastructure and standardization of services, the industry has become an important component of the global economy. Tourism’s contribution to employment is particularly noticeable: every tenth job is related to this sector, with women occupying 54% of such positions, which distinguishes tourism compared to 39% in other sectors.

According to the World Tourism Organization, in 2022, the industry’s revenues contributed 10.2% to the global gross domestic product, while accounting for 30% of global services exports. For 38% of countries, tourism has become the main source of foreign exchange. Before the pandemic, annual growth in international tourism was maintained at 5.1%, reaching 1.5 billion international travelers in 2019.

Europe continues to traditionally hold a leading position in world tourism. In 2023, EU countries accounted for more than half of international tourist arrivals, generating around €407 billion. In terms of regions, Europe controls 51% of the world tourism market, surpassing regions such as Asia (25%), North and South America (30%), Africa (16%) and the Middle East (5%). In Europe, there is a predominantly domestic tourism trend, as only 9% of Europeans prefer to travel outside their own region. The preference for local destinations is confirmed by the fact that every second European travels within the continent at least once a year. The GDP from tourism in the EU as a whole amounted to 10.4%, with particularly high figures in the economies of such countries as Croatia, Iceland, Greece, Portugal, Spain, Italy and Malta, while in Scandinavia and Eastern Europe the tourism sector is of lesser importance.

Since 2007, a comprehensive metric tool, the Travel and Tourism Competitiveness Index (TTCI), has been used to assess the competitiveness and sustainable development of the tourism sector. This comprehensive tool was developed by the World Economic Forum (WEF) in collaboration with global industry and business organizations and covers 140 countries.

The TTCI index combines four sub-indices based on 14 variables and 90 precise indicators that assess both direct and indirect factors that influence the success and progress of tourism.

Among these factors, the key ones are the quality of the business climate, the effectiveness of legislation for business, the infrastructure of safety and health, the advancement of education and transport, the flexibility of the labor market, innovation indicators, such as the level of R&D, the prevalence of mobile phones and the Internet among the population. Also significant are the priorities of state policy in the field of tourism, price competitiveness, environmental sustainability and cultural and natural resources.

An analysis of World Economic Forum data demonstrates the superiority of the European Union (EU) in the field of tourism competitiveness: the average TTCI index for EU countries is 4.3, which is higher than the average values for the Americas (3.9) and Asia (4.2). Notably, of the 30 countries with the highest index, 16 are in the EU, led by the triumvirate of Spain, France and Germany, each with an index of 5.4, adjusted for the latest assessments. This significantly exceeds the average indicators not only for Europe, but also for the world as a whole (3.8). For example, Italy, Greece, Austria and Portugal are also significantly ahead in the ranking. At the opposite end of the spectrum, Cyprus closes the list of European countries in the integral index, occupying 44th place, however, there is a positive trend - an increase of 8 positions since 2018, thanks to active government actions to support the tourism industry.

The European Union dominates in many key areas of competitiveness assessment, with excellent results in security (score 5.8 out of 7), health (score 6.2), education (score 5.0) and information technology (score 5.4). Although slightly lower in tourism infrastructure (4.9), land transport networks (4.1) and environmental sustainability (4.7), these are still above average and indicate a high quality of service on offer.

However, there are some areas of concern, such as the state of the business environment, the development of the aviation industry and innovation progress, where Europe has room for improvement. According to the Global Innovation Index 2020, only four European countries - the Netherlands, Denmark, Finland and Germany - are in the top 10 innovation leaders. High costs of tourism services due to hotel pricing policies, tourist taxes and high fuel excise duties, as well as strict visa policies, may also limit the EU's competitiveness.

However, the key indicators for determining the potential of the sustainable tourism sector in the EU countries in the near and long term are factors that assess the natural and cultural potential, the environmental sustainability of the region and the priority of this sector in state policy.

In the 20th century, the concept of sustainable development gained significant momentum as a decisive principle for socio-economic systems. Over time, anthropogenic influence led to the disruption of the natural self-regulating processes of the biosphere, which, in turn, provoked global environmental shifts and affected the deterioration of the quality of life on the planet.

In response to growing concerns about the ecological state of the planet and the future of human civilization, in 1983 the UN initiated the creation of the Commission on Environment and Development, headed by Norwegian Prime Minister Gro Harlem Brundtland. The Commission's task was to analyze the complex interrelations between environmental and socio-economic problems and to develop sustainable development strategies for different regions of the Earth. This time was characterized by an understanding of the need to update approaches to global development.

"Sustainable development" was formally defined in 1987 by Brundtland in a report entitled "Our Common Future". The essence of this concept is to achieve the needs of modern society without compromising the opportunities of future generations. Key aspects of sustainable development include meeting the basic needs of the least protected sections of the population and taking into account the environmental limitations determined by the state of existing technologies and social organization.

Today, tourism plays a fundamental role in the global economy, attracting millions of people who travel for leisure, business or cultural enrichment. Despite its significant contribution to economic development, this sector also poses a number of serious environmental and socio-economic challenges. Therefore, the industry needs to transition to a sustainable tourism model that could combine economic efficiency with environmental protection and social justice.

The economic efficiency of tourism reflects the degree of optimal use of resources over a certain period of time. It depends on the level of tourism services in the region, the organization of tourism activities in the country and the efficiency of tourism companies.

The magnitude of the economic return of tourism is related to a number of criteria:

1. Equal distribution of economic benefits. Tourism can promote economic equality by attracting investment and generating income that is dispersed across all levels of society within the local economy.

2. Increasing the prosperity of key economic sectors. The revitalization of the tourism industry stimulates the development of subordinate sectors such as the hotel and transport business, as well as information and tourism services, increasing their profitability.

3. Additional financial flows. Tourism accelerates the economic enrichment of the region by attracting external resources, thereby ensuring the diversification of the local economy and stimulating the development of additional business areas.

4. Infrastructure upgrades. The tourism industry is a powerful catalyst for upgrading local infrastructure, including media, utilities and transport networks, which generally improves the quality of life of the population and makes the region more attractive to visitors.

The social effectiveness of tourism is manifested through the improvement of living conditions of society and successful activities in the field of tourism and recreation, influencing the social well-being of the local population.

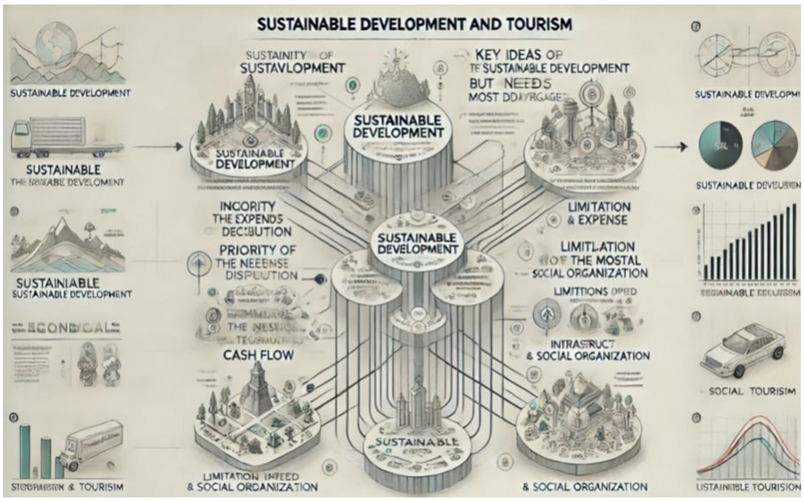

Figure 2: *The relationship between sustainable development and tourism*
(*Source: author's development*)

Community involvement is a critical element in the success and sustainability of eco-tourism initiatives. Engaging local communities not only enhances the effectiveness of eco-tourism but also ensures that the economic benefits are equitably distributed, fostering social cohesion and environmental stewardship. This subsection explores the significance of community involvement in eco-tourism, outlining key benefits and strategies for effective engagement.

1. Empowerment and Capacity Building

One of the most significant advantages of involving local communities in eco-tourism is the empowerment it provides. When communities actively participate in eco-tourism planning and decision-making, they gain a sense of ownership over the resources and projects that affect their lives. This empowerment is essential for fostering a culture of sustainability, as community members become advocates for environmental protection and responsible tourism practices.

Capacity-building initiatives are crucial for equipping local residents with the skills and knowledge necessary to engage effectively in eco-tourism. Training programs focused on hospitality management, customer service, environmental education, and marketing can enhance the ability of community members to contribute meaningfully to eco-tourism efforts. These initiatives not only improve individual livelihoods but also strengthen the overall community's resilience to economic and environmental changes.

2. Cultural Preservation and Heritage Promotion

Community involvement in eco-tourism provides an opportunity for local residents to share their cultural heritage and traditional practices with visitors. This cultural exchange enriches the travel experience for tourists while promoting the preservation of local traditions and customs. By showcasing their unique cultural identities, communities can attract visitors interested in authentic experiences, which can differentiate them from more conventional tourist destinations.

For example, eco-tourism projects that involve local artisans, musicians, and storytellers can create immersive experiences for tourists that celebrate the community's cultural heritage. This not only enhances the tourist experience but also provides a sustainable source of income for local artists and cultural practitioners, helping to maintain the community's cultural identity amidst globalization.

3. Sustainable Resource Management

Involving local communities in eco-tourism also leads to better resource management and conservation outcomes. Community members often possess valuable knowledge about local ecosystems and sustainable practices, which can be leveraged to enhance conservation efforts. When communities are invested in eco-tourism, they are more likely to engage in practices that protect their natural environment.

Participatory resource management approaches, such as community-led conservation projects, can be effective in ensuring the sustainable use of natural resources. For instance, in many eco-tourism areas, local communities have taken the lead in establishing conservation areas, implementing sustainable fishing practices, and protecting endangered species. By giving communities a stake in resource management, eco-tourism can foster a sense of responsibility and stewardship that benefits both the environment and the local economy.

4. Economic Benefits and Job Creation

Community involvement in eco-tourism initiatives directly translates into economic benefits for local populations. By engaging local residents as guides, operators of eco-lodges, and participants in cultural programs, eco-tourism can create job opportunities and generate income within the community. These economic benefits are particularly crucial in rural and marginalized areas where traditional livelihoods may be threatened by climate change and other factors.

Furthermore, eco-tourism can stimulate local economies by encouraging the development of related industries, such as handicrafts, food production, and transportation services. The infusion of income from eco-tourism can lead to broader economic development, improving infrastructure and access to services for the entire community.

5. Strengthening Social Cohesion

Community involvement in eco-tourism can also strengthen social cohesion and foster a sense of community pride. As local residents work together toward common goals, such as preserving their environment and promoting their culture, social bonds are strengthened, and community identity is reinforced. This social capital is vital for resilience, enabling communities to adapt to changes and challenges more effectively.

Additionally, when communities collectively participate in eco-tourism, they are better equipped to voice their needs and concerns to external stakeholders, including government entities and tourism organizations. This enhanced advocacy can lead to more inclusive decision-making processes that reflect the interests and aspirations of local residents.

In summary, community involvement is a cornerstone of successful eco-tourism initiatives. By empowering local residents, promoting cultural preservation, improving resource management, generating economic benefits, and fostering social cohesion, community engagement enhances the sustainability and effectiveness of eco-tourism projects. Stakeholders in the tourism industry must prioritize the involvement of local communities in eco-tourism planning and implementation, ensuring that the benefits of eco-tourism are shared equitably and that communities are active participants in shaping their futures.

Based on the information presented in the table, France, Spain and Italy stand out among the world leaders in terms of the volume of natural and cultural resources with an index approaching six, and are second only to China. Significant biological and landscape diversity is characteristic of the territory of the European Union. Despite the high population density and active economic processes, the EU has preserved exceptional ecosystems to a sufficient extent - from mountain peaks to coastlines and marshy areas. Europe's natural wealth is unique due to its geographical diversity with many islands, as well as variability in geological, orographic, soil, climatic and cultural contexts.

The European Union stands out in particular for its number of protected natural areas. As of 2023, Spain has 49 biosphere reserves out of 686 recognised globally, in addition to hundreds of national parks, game reserves and other protected natural areas. Such sites account for more than a quarter of the EU's land and inland waters, as well as almost a third of its territorial waters. Europe is responsible for 65.6% of all protected natural area locations registered by the UN, although they represent only 12.9% of the world's land area, highlighting the comparatively small size of these areas in Europe.

Europe's cultural and historical contribution is comparable to its natural wealth and is expressed in the diversity of cultures that have left their mark on human history. In 2020, 22% of UNESCO's World Heritage Sites are located in Europe, with Italy leading the list (54 sites), followed by Spain (47) and France and Germany (44 each). This heritage reflects not only architectural structures, but also regional traditions - such as festivals, music, dance, customs and gastronomy - that define the unique cultural essence of European countries.

Cultural and environmental interests of tourists have become key factors influencing the tourism economy. Modern travelers are increasingly abandoning ordinary beach holidays in favor of unique cultural and natural places. They are ready to invest in excursions to historical places, visits to national parks and reserves, as well as in the experience of immersion in the cultural environment and life of local residents.

Growing demand for personalised and eco-conscious tourism is supporting a variety of forms, from green tourism to agritourism and food tours. These destinations are becoming increasingly popular and are showing significant growth. Sustainable tourism is moving from niche to mainstream, with 87% of users of leading booking platform Booking.com stating their willingness to follow its principles.

A significant statistic is the growth rate of ecotourism revenues, which are at 20% annually – six times higher than the overall growth in the tourism industry. This data indicates a change in priorities in tourist behavior, a switch to a more conscious and responsible approach to travel, and highlights the importance of sustainable development in the global tourism industry.

In the field of tourism, the main social performance indicators include the following aspects:

- improving the quality of life of the population in regions with developed tourism, which contributes to raising their well-being;

- modernization of recreational infrastructure, creating conditions convenient for both visitors and local residents;

- protection of natural and cultural values in order to preserve historical and natural monuments; putting unused territories into circulation, which allows for the rational use of land resources; providing education and qualifications to local residents to create new jobs and develop skills;

- strengthening cultural ties through the promotion of mutual cultural enrichment and cooperation with neighboring territories.

Sustainable tourism requires an active environmental approach that includes minimizing environmental impacts, such as pollution control, conservation of natural resources, creation of protected areas, and efficient waste management. This approach is responsible for reducing adverse effects on ecosystems, such as loss of biodiversity or pollution, and preventing an increase in the carbon footprint of transport and construction.

Sustainable tourism must also support social development in host regions by involving local communities in tourism projects and ensuring that benefits are fairly distributed. It is important to protect and promote local traditions to avoid loss of identity and cultural traditions. Tourism can be a source of social transformation, cultural exchange and understanding, but it can also cause negative consequences such as cultural commodification and the destruction of traditional ways of life.

Community participation and empowerment are essential to sustainable tourism. Important components include protecting cultural identities, supporting community enterprises, and ensuring fair sharing of economic benefits. While tourism provides economic benefits through employment and infrastructure, over-reliance on the industry can lead to economic vulnerability. Sustainable tourism strategies focus on economic diversity, supporting local entrepreneurship, and implementing responsible tourism practices to ensure long-term economic stability.

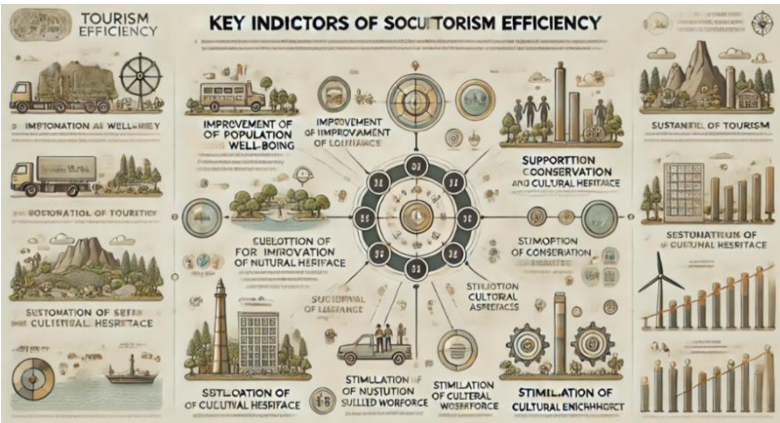

Figure 3: *Key indicators of social performance of tourism, as well as its impact on the environment, social and economic aspects (Source: author's development)*

Unfortunately, as tourism grows, its negative effects become more visible and cause ever greater concern. Experts emphasize that approximately half of the natural and cultural heritage sites are currently under severe pressure due to the intensive tourist flow. Standardized mass tourism can lead to environmental degradation, pollution and, in extreme cases, destruction, threatening the ecological balance of such places.

Climate change is one of the major challenges facing the modern world, and tourism plays its part. According to data, the tourism industry produces between 5 and 12.5 percent of global carbon dioxide emissions, taking into account the contribution of all greenhouse gases that add to the problem of global warming. The bulk of these emissions come from transport, with air travel responsible for 40 percent, as it provides more than half of international tourist movement, and road transport for 32 percent. Hotel services and their impact on the climate account for 21 percent of emissions, including the energy consumed by air conditioning, heating and maintaining swimming pools.

If current tourism trends continue, CO_2 emissions could increase by 135% by 2035, which would have a catastrophic impact on the environment, the ozone layer and natural resources, not only in popular tourist regions of Europe but also worldwide. This prospect highlights the need for urgent action to reduce the carbon footprint of the global tourism industry.

Abstract

The development of modern society poses a number of new problems to the domestic education system due to political, socio-economic, socio-cultural, technical, technological, environmental and other factors, among which the issue of improving the quality and accessibility of education due to the growth of human capital should be highlighted.

The fundamental processes taking place in the education system lead to the formation of a new ideology and methodology of education as an innovative direction in this key area today. Innovative learning technologies should be investigated as a mechanism for implementing a fundamentally new educational paradigm.

The main goal of innovative technologies in the field of education is:

- *the developing the ability to motivate actions;*
- *the ability to use the latest achievements of science and practice;*
- *the formation of creative unconventional thinking;*
- *the preparing an individual for life in an ever-changing world;*
- *the qualitative change in the students' personality compared to the traditional system*
- *the ability of using digital technologies and distance learning to implement opportunities for providing on-the-job training;*

The essence of such training is to focus the educational process on the potential of a person and their implementation. Education should develop mechanisms for innovation, find creative ways to solve vital problems, and contribute to the transformation of creativity into the norm and form of human existence.

All this becomes possible thanks to the introduction of didactic and educational programs that are not known in practice into professional activities, as well as new approaches to student training. Innovative activity in education as a socially significant practice aimed at moral self-improvement of a person is important because it is able to ensure the transformation of all existing types of practices in society.

Keywords: education, innovation, human capital, potential, quality of life, standard of living of the population, innovative teaching method

I. Introduction

In the conditions of the modern world, characterized by a change in the educational paradigm, as well as the strengthening of the role of human capital in innovative economic development, the educational sphere acquires a new vector – growth and prosperity.

The processes associated with the modernization (innovation) of education, the development of newfangled technologies and techniques for acquiring relevant skills have ceased to be somewhat unique. The lack of individuality of the process is interdependent not only with the transition of a social society to post-industrialism, but also with a collision with spontaneous, unexplored and non-economic laws that do not depend on the desire and ability of mankind by phenomena such as the new corona virus infection (2020), which provoked forced social isolation, on the one hand, and rebuilt the ongoing economic processes caused by the need for communication in an alternative format with another.

It was an impetus to rethink the directions of economic development as the introduction of active interaction and long-term partnership in the scientific and educational sphere, both for leading technology giants and for small enterprises, regional scientific and educational organizations.

The Era of innovation requires attention and support for human capital, since this is one of the key factors in which a person and his abilities, knowledge can play an important role, declared not only at the national level, but also on the world stage. In this regard, science and education act as the main guide towards achieving the main goals of a global scale, such as the export of personnel and technology, finding innovative talents, increasing labor productivity, and promoting scientific and educational infrastructure.

The indicator of innovation activity is:

• The amount of invested financial resources;
• Transfer of decades of accumulated knowledge in various fields;
• Relevance and search for incentives due to in-depth research in the future.

The use and dissemination of knowledge contributes to the enrichment of a person as a person, and the educational environment as the results of scientific research and the process of formation of educational markets. According to analysts, the innovative educational market will reach $404 billion next year (2025), and $10 trillion in five years [8]. The dynamics of market growth is multidirectional and its high growth rates are most often observed in developed countries.

With regard to the structure of the Russian education system, the growth trend is observed in the share of online education due to some factors, such as:

• increased demand for online education;
• increased demand for IT professionals;
• strengthening digitalization processes;
• expanding the market for competitive platforms;
• Changing consumer tastes, preferences, and learning approaches.

By developing these processes, it will be possible to solve the tasks of ensuring the competitiveness of highly qualified specialists, which are based on innovative progress.

II. Methods

- the modern theoretical and practical development of innovation;
- the statistical dates and analyses;
- the innovative approach to the reproduction of human capital;
- the determination of the impact interaction of science and education on human capital development in an innovative economy through an intersectoral transformation cycle, which demonstrates the role mechanism of reproduction of human capital.

III. Results

The application of the proposed recommendations by the state in practice and improvement of socio-cultural and economic policies in the future. The reliability of the statistical and factual data used has also been determined. The results are justified by the confirmation of their publications in leading peer-reviewed scientific journals.

IV. Discussion

The level of education is a significant indicator of a person's quality of life. It acts as an integral part of human existence, determining its success. It acts as an integral part of human existence, determining its success. Specifically the education - is a key factor in the development of the economic situation in the country, since it contributes to the formation of public culture and the definition of progress in Technique and Technology, strengthening individual moral satisfaction with the standard of living.

Therefore, the head of state has frequently mentioned the importance of providing high-quality education and the diverse development of social society in the contemporary world.

Today, the growth of human potential and its future success depend on the level and quality of fundamental education through innovation. The innovative method of teaching in schools and helps the preschool institution growing generation, the future personnel of our country to take the first, but very important step towards the well-being of their own lives. Certainly, for these purposes, it is necessary to create all possible conditions for expanding the networks of secondary education institutions so that children are brought up in the spirit of patriotism and professionalism.

Only educated and literate youth with modern skills and professions can contribute to the state development. Particularly for this reason that is important to pay attention to the education system's development, since the growth of literacy among the population is a factor determining the strength and prosperity of any state society.

Young people with innovative ideas and skills become active supporters of processes that directly lead to a better life. This is the only way to build a society based on innovative knowledge and high culture.

There are quite a lot of studies in science on the importance of increasing investment in education. In particular, Russian cultural critic Andrei Flier also noted that "The less money the ruling elite invests in culture and education today, the more it will have to invest in the police, justice and penitentiary system tomorrow [4]."

Therefore, the purpose of the Law on Education and Parental Responsibility for the Education and Upbringing of Children was to strengthen their obligation to lay the foundations for the physical, moral and intellectual development of the child's personality.

But, unfortunately, the problems that were inherited from the education system of the 90s have greatly worsened, even other newer ones have appeared, which did not take place at all earlier or were successfully solved by the authorities. The process of degradation in the education and cultural system of those years was accompanied by a lack of financial and logistical resources [1].

The volume of state funding for Russian education has significantly decreased. At the same time, therefore, there was a tendency for the indicator of spending on the educational sector to decrease as a % of GDP.

In those years, the decline in real spending on education and the average salary in this industry were precipitous. There was a significant deterioration in the state of the material and technical base of educational institutions.

According to the data, in government spending on education (in %) to GDP, there was a downward jump from 1991 to 2000 - from 3.6 to 3%. Also, the average salary in the field of education (in %) relative to the subsistence level has significantly decreased by several times - up to 85 [3].

Russia was not only different from developed countries, but also from European countries with economies in transition. The increase in the share of public spending on education in GDP allowed most of these countries to almost no to reduce spending on education at comparable prices during the economic downturn that accompanied economic reform. In most of these countries, the average wage of education workers has not fallen below the average wage of those employed in the economy. Some education indicators financing during the economic downturn in European countries with economies in transition showed the opposite figures, in short, a tendency to increase significantly, especially when observing education expenditures (in%) to GDP [6].

Consequently, this situation has had a negative impact on the socio-cultural standard of living among the population, in particular:

- reduction in the number of students;
- increase in types of training on a commercial basis;
- decrease in publishing activities;
- closure of many libraries,
- houses of culture;
- reduction of visitors to theaters, cinemas, and museums.

Relatively the mental work has moved into the background.

IV. Subsection Four

But, thanks to the measures taken, the skillful policy of the state has managed to achieve some positive results. Gradually, step by step, the situation began to change for the better. Starting in 2000, the country embarked on the path of creation and turned into a great power, in which the standard of living is quite consistent with many European states. Maybe not the most advanced, but we are only at the beginning of the journey.

The implementation of national projects has contributed to a serious change in the infrastructure of the population's life in such areas as:

- health;
- education;
- sport;
- agriculture.

It is clear that education could be done as in England or Switzerland. Nevertheless, there was a noticeable difference between what was and what has become: new schools, computer classes, the Internet and more. First of all, attention was focused on improving the population standards of living by increasing the level of education.

The educational space is built on the basis of basic academic values and demonstration of quality. Quality assessment covers teaching and research, leadership and management, the ability to meet student needs and the provision of non-educational services.

Quality in education is a fundamental condition for trust, relevance, mobility, compatibility and attractiveness in a given space.

As you know, in the Russian Federation, primary and secondary forms of education are mainly public, and in recent years a private form of education has been developing strongly. There is an opinion that the quality of the private form of education is much better than the public one, since it is dominated by an innovative modern teaching method.

However, in practice, even in government structures, education is gradually becoming more and more a paid service, but the quality of education is not improving. At the same time, according to parents, even a 20% drop in income does not lead to a massive rejection of paid education.

Recall that according to the Constitution, the State guarantees the accessibility and free of charge of preschool, basic general and secondary vocational education.

More than 60% of students after grade 9 go to colleges, technical schools and vocational lyceums for secondary special education, while a minority remains in schools.

Teachers have to work because of the remaining participants, although there is less and less demand for them. And schools receive funds from those who want to stay after grade ninth to study in high school and prepare for the Unified State Exam [7].

The desire for students to receive secondary special education is supported, because the country needs workers, not bloggers, as say.

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

Nevertheless, the experience of the top five countries in the world (Table No.1), where the level of education is the highest among the rest, shows that the transition to full-time paid education contributes to the development and achievement of a higher quality of education. However, in this matter, in the economic conditions of our country, there is a problem ... since a significant part of the population (middle-income population) has low purchasing power, there is a high level of idle production facilities, relatively high levels of poverty and unemployment remain, and this approach is not entirely acceptable.

The following table shows the ranking of countries in the world by level of education according to the UN data published by 2024 (the index is updated once within two to three years). The index is measured by the country's achievements based on the achieved level of education of the population by two main and necessary indicators: the adult literacy index; the index of the total proportion of students receiving primary, secondary and higher education.

Table 1: *Ranking of countries in the world according to the education level index United Nations Development Programme: Education Index 2024 [5].*

№	Country	Expected duration of study (in years)	Average duration of study (in years)	Education Index
1	Australia	21.1	12.7	1.01
2	New Zealand	20.3	12.9	0.99
3	Iceland	19.2	13.8	0.99
4	Sweden	19.4	12.6	0.96
5	Belgium	19.6	12.4	0.96
11	Germany	17.0	14.1	0.94
17	United States of America	16.3	13.7	0.91
29	Russia	15.8	12.8	0.85
33	Georgia	15.6	12.8	0.89
36	Kazakhstan	15.8	12.3	0.82
47	Belarus	15.2	12.1	0.8
58	Ukraine	15.0	11.1	0.74
76	Kyrgyzstan	13.2	11.4	0.76
77	Turkmenistan	13.2	11.3	0.74
80	Uzbekistan	12.5	11.9	0.73
101	Tajikistan	11.7	11.3	0.68
188	Burkina Faso	9.1	2.1	0.3
191	Niger	7.0	2.1	0.24

The table's figures show that Australia is ahead of New Zealand in this ranking, taking 1st place. In this top five, New Zealand shares the same education index with Iceland - 0.99. Norway is in the second five in this list, although it was in the first in the previous calculation. Germany also lost its leading position (2020), falling to the eleventh position with an index of 0.94, and the United States of America shared this group with it with an index of 0.91.

Among the CIS countries, Russia, ahead of Kazakhstan by 3 positions, is among the third ten countries in the world, ranking 33rd with an index of 0.85, therefore, Kazakhstan is awarded a relatively decreasing index of 0.82.

Belarus ranks in the fourth ten in this ranking, although it was in the thirtieth place (rating for 2020).

Uzbekistan and Tajikistan are gaining a downward trend, as they complete the first half of the list with an education level index of 0.73 and 0.68. Countries such as Mozambique, Ethiopia, Chad, Burkina Faso and Niger occupy the last places from 165 to 191 with indices 0.3 - 0.24 in the list of countries in the world by level of education [9].

In the world of innovative, during the process of changing the structure on employment and increasing the share of intellectual labor, the share of low-skilled labor is simultaneously decreasing. It is the level and quality of education that is one of these sources of human capital.

Innovative education is the intellectual values of a person, the acquisition of skills and abilities aimed at creating socially significant values, and its purpose is to inherit intelligence and the ability for implementation in creative work.

Hence, it follows that the key factors determining the intellectual potential of an individual in any state of the world include the following:

- Political development;
- Economic development;
- Social development;
- The content and quality of education.

If we take into account the conditions of the information age, then the main activity in the field of education will take place under the following mottos as its role and functional structure.

The functional structure is based on levels that meet the requirements of the current society, quality and internationalization - local, national and international.

In human (person), the experience of one individual does not disappear after its death, but accumulates in society due to the developed mind of people and their ability to communicate.

In modern conditions, market institutional transformations have a very significant impact on the standard of living of the population and the development of human capital.

As noted above, the innovative education occupies an important place among the new society and it belongs to strategically important areas of activity that could determine the human capital quality. Based on this, the following measures should be taken in this direction:

- to increase the professional competence of teachers, both in higher and secondary educational institutions through professional development systems every three years at the expense of centralized state budget funds;

- to ensure the flexibility of the vocational education’s structure to changes in the labor market;

- to organize close relations between the branches of the national economy and the higher education system for the effective use of labor resources;

- to strengthen the target orientation towards the system of training specialists for the needs of the national economy of the country;

- to provide targeted social support to the population’s low-income segments in terms of obtaining professional higher education;

- to transfer priority to the public sector for social support of the population, it is necessary, in the issue of the secondary education development;

- to ensure the adaptation of the education system to market conditions.

In general, the recommended directions for improving the branches of the social sphere in the scientific and methodological aspects, although is not a complete system of measures, will make a significant contribution to improving the country's population standard of living for the near future.

The education system, like the rest of the systems that make up the social sphere, depends entirely on the support from the state.

Education reform should take into account the interests of every economic agent. However, the responsibility in this area is too high, because it determines the future of a person.

In order to increase the accessibility of higher education and respect the principle of fairness and transparency in university admissions, the Government has created a Unified State Exam for the younger generation from low-income families, which has become the main link in the national knowledge assessment system.

However, as practice shows, despite efforts aimed at creating conditions on the part of the Government for the education of a growing number of school-age children, the quality of education of the young population has decreased according to the test results. Creating conditions for the education system is becoming a difficult task that affects the economy as a whole. The acute shortage of qualified pedagogues is associated with the outflow of personnel from the education system for economic reasons, due to unworthy wages, having a serious impact on all levels of the education system - from preschool to higher education.

Today, it is necessary to support the low-paying population with budgetary higher education by financing.

Consequently, in 2024, the state provided more funds for the development of the education sector, as budget expenditures increased to 575.2 billion rubles in accordance with the state program "Development of Education".

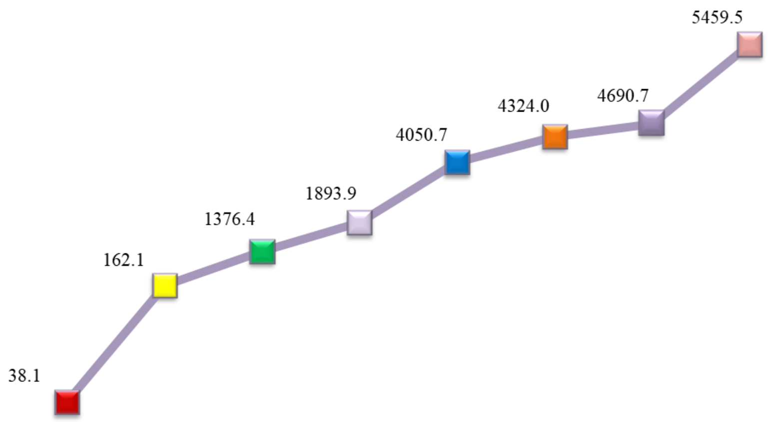

Figure 1: *State budget expenditures on Education in Russian Federation, in bln. ₽ from 2000 to 2023*

At the same time, the indicators of the draft federal budget for this state program compared with the current Federal Law for 2023-2025 in 2024 [2] which increased by 19.9 billion rubles, in 2025 – by 21.7 billion rubles, therefore in 2026 – by 14.6 billion rubles. It should be emphasized that the amount of funds for the implementation of the national project "Education" in 2024 has not decreased and corresponds to previously accepted parameters. In 2025 and 2026, it increased by 2.7 and 2.3 billion rubles, respectively.

One point one billion rubles are additionally provided for the implementation of secondary vocational education (SVE) programs in 2024, 4.2 billion rubles in 2025, and 4.1 billion rubles in 2026 (Figure 1).

We believe that in this context, the State should ensure general access to education through the implementation of the following programs:

- public support for students from low-income families, orphans and gifted children;
- development of a long - term lending system;
- ensuring the flexibility of the structure of vocational education to changes in the labor market;
- organization of close relations between the branches of the national economy and the higher education system.

The analysis of these trends in the changing role of knowledge and education in socio-economic development allows us to conclude that the fundamental change in the function of the social institution of education in the material and spiritual reproduction of the living conditions of society and man. In the context of the growth of scientific, intellectual, educational capacity and high rates of change in the world, innovative education becomes the basis for the successful functioning of the economy and all processes of reproduction of society.

In summary, in our view, the recommended directions can make a certain contribution for improving the country's population standard of living in nearest future.

Abstract

In the context of a worsening environmental crisis and the urgent need for a transition to sustainable development, tax reforms have emerged as a vital mechanism for stimulating green entrepreneurship.

This paper provides an in-depth analysis of global trends in tax reforms aimed at supporting environmentally responsible businesses and examines the regional variations in their implementation. Tax incentives have proven to be effective tools for encouraging companies to adopt eco-friendly practices, invest in renewable energy, and develop innovative solutions that address pressing environmental challenges.

This study categorizes various forms of tax incentives, such as tax credits, exemptions, and reductions for businesses engaged in sustainable practices, including renewable energy production, waste management, and sustainable agriculture. The paper highlights successful case studies from diverse countries, showcasing how tax reforms have effectively driven the growth of green entrepreneurship. For instance, nations such as Germany and Sweden have implemented robust tax policies that incentivize renewable energy investments, resulting in significant advancements in green technology and job creation. Similarly, developing countries, like Kenya and India, are leveraging tax incentives to foster eco-entrepreneurship, balancing economic growth with environmental protection. Furthermore, this study delves into the challenges and opportunities associated with these tax reforms. While many countries are adopting fiscal measures to stimulate green entrepreneurship, the effectiveness of these reforms can vary significantly due to factors such as economic capacity, political will, and regional environmental priorities. Developing nations often face constraints in their ability to implement comprehensive tax incentives, while developed countries may benefit from more substantial financial resources to support such initiatives.

Keywords: green entrepreneurship, tax reforms, eco-innovation, renewable energy, global trends

I. Introduction

As the world grapples with an escalating environmental crisis characterized by climate change, biodiversity loss, and resource depletion, there is an urgent need for innovative solutions that promote sustainability. Green entrepreneurship has emerged as a vital component in this effort, encompassing businesses that prioritize environmental stewardship, social responsibility, and sustainable practices. These ventures not only aim to create economic value but also seek to address pressing environmental challenges, making them essential players in the transition to a sustainable economy.

Tax reforms represent a powerful policy tool that governments can leverage to stimulate green entrepreneurship. By providing financial incentives and support through tax credits, exemptions, and reductions, policymakers can encourage businesses to adopt environmentally friendly practices, invest in renewable energy sources, and develop sustainable technologies. Such fiscal measures are increasingly recognized as essential strategies to align economic development with environmental sustainability, fostering an ecosystem where green businesses can thrive.

Globally, there has been a noticeable shift in how countries approach taxation in relation to environmental goals. Governments are increasingly integrating sustainability into their fiscal policies, with a growing recognition that effective tax reforms can lead to significant advancements in green innovation. For instance, countries like Germany and Denmark have implemented substantial tax incentives for renewable energy investments, resulting in marked improvements in their energy mix and reductions in greenhouse gas emissions. Conversely, developing nations are beginning to explore tax reforms as a means to cultivate green entrepreneurship, aiming to balance economic growth with environmental protection.

However, the implementation and effectiveness of tax reforms can vary widely based on regional contexts, economic capacities, and political landscapes. While developed nations may have more resources to allocate toward substantial tax incentives, developing countries often face challenges related to limited budgets, infrastructure deficits, and competing economic priorities. This disparity leads to diverse approaches in the application of tax reforms, with each region exhibiting unique characteristics in its efforts to stimulate green entrepreneurship.

Moreover, the role of international frameworks, such as the United Nations' Sustainable Development Goals (SDGs), cannot be overlooked. These goals provide a comprehensive blueprint for countries to align their national policies with global sustainability objectives, creating a cohesive framework for implementing tax reforms that support green entrepreneurship. By integrating tax policies with broader environmental strategies, governments can create a conducive environment for innovation and sustainable business practices.

This paper aims to explore the global trends and regional features of tax reforms designed to stimulate green entrepreneurship. By analyzing successful case studies, identifying challenges, and assessing the impact of these fiscal policies on environmental and economic outcomes, the study seeks to provide a comprehensive understanding of how tax reforms can be utilized to foster sustainable business practices worldwide. The following sections will investigate the types of tax incentives commonly used, the regional differences in their application, and the broader implications of these reforms for the global transition to a green economy.

In summary, tax reforms are essential for driving the growth of green entrepreneurship and encouraging businesses to adopt sustainable practices. As countries strive to balance economic development with environmental stewardship, understanding the role of fiscal policies in promoting eco-innovation and reducing ecological impacts is crucial for shaping a sustainable future.

II. Methods

This study employs a multi-faceted approach to analyze the impact of tax reforms on stimulating green entrepreneurship. The methodology includes three primary methods: a **literature review**, **case study analysis**, and **quantitative data analysis**. Each method is designed to provide a comprehensive understanding of the relationship between tax reforms and green entrepreneurship, emphasizing global trends and regional features.

1. Literature Review

The first method involves conducting an extensive literature review to establish a theoretical framework and identify existing knowledge on tax reforms and green entrepreneurship. This review will focus on:

- **Defining Key Concepts:** Understanding the definitions and characteristics of green entrepreneurship and how tax reforms can influence its growth.

- **Identifying Global Trends:** Examining various tax policies implemented worldwide that aim to promote environmentally friendly business practices.
- **Highlighting Best Practices:** Exploring successful examples of tax reforms that have effectively stimulated green entrepreneurship, drawing insights from academic articles, policy reports, and industry publications.

The literature review serves to contextualize the research and identify gaps in current knowledge that the subsequent methods will address.

2. Case Study Analysis

The second method consists of qualitative case study analysis, focusing on specific countries or regions that have implemented tax reforms to foster green entrepreneurship. This analysis will include:

- **Selection of Case Studies:** Identifying diverse examples from both developed and developing countries that illustrate various approaches to tax reforms. Potential case studies may include:
- **Data Collection:** Gathering qualitative data through interviews with stakeholders, such as policymakers, entrepreneurs, and environmental experts, to understand their perspectives on the effectiveness of tax reforms.
- **Impact Assessment:** Evaluating the outcomes of these case studies in terms of job creation, investments in green technologies, and reductions in environmental impact.

The case study analysis provides practical insights and examples that can illustrate the theoretical concepts identified in the literature review.

3. Quantitative Data Analysis

The third method involves quantitative data analysis to evaluate the statistical relationship between tax reforms and green entrepreneurship. This analysis will include:

- **Data Collection:** Gathering quantitative data from various sources, including national statistics, international databases (such as the World Bank and OECD), and reports from environmental agencies. Key indicators may include:
- **Statistical Analysis:** Using statistical techniques, such as regression analysis, to explore correlations between the implementation of tax reforms and the growth of green entrepreneurship. This analysis aims to quantify the impact of specific tax incentives on key economic and environmental outcomes.
- **Comparative Analysis:** Assessing differences in the effectiveness of tax reforms across regions and countries, identifying which strategies yield the best results in promoting green entrepreneurship.

By employing these three methods—literature review, case study analysis, and quantitative data analysis—this study aims to provide a comprehensive examination of the role of tax reforms in stimulating green entrepreneurship. The combination of qualitative and quantitative approaches will allow for a deeper understanding of how fiscal policies can effectively promote sustainable business practices and contribute to a more environmentally responsible economy. The findings will offer valuable insights for policymakers, entrepreneurs, and researchers seeking to enhance the impact of tax reforms on green entrepreneurship.

III. Results

Industrialization has resulted in significant pollution emissions alongside economic growth. Although Russia has experienced rapid economic development and improvements in living standards, environmental pollution remains a serious issue. According to Yale University's 2022 Global Environmental Performance Report, Russia ranks 160th out of 180 countries in terms of environmental performance. As a major contributor to pollution, the environmental management practices of enterprises have garnered increasing attention. Green innovation has emerged as a crucial technological solution for achieving corporate transformation, promoting clean production, and ensuring sustainable development. Various measures have been proposed to foster the advancement of green innovation within businesses.

As of 2019, Russia's Ministry of Science and Technology reported that the country invested approximately 2.2 trillion rubles in research and development (R&D), representing a 12.5% increase from the previous year and accounting for 2.23% of GDP. Of this amount, enterprises contributed 1.69 trillion rubles to R&D, an increase of 11.1% over 2018. To alleviate the R&D burden on companies and encourage them to engage in their own research, the government implements various industrial policies, using tax incentives and subsidies as primary regulatory tools. However, the effectiveness of these two intervention methods is a topic of debate, leading scholars to investigate their impact on firms' R&D performance and the extent of that influence.

With the advent of Keynesian neoclassical economics and theories of government failure, researchers began examining the effects of policies on green innovation. Studies have found a positive relationship between subsidies and firms' green innovation. However, some scholars argue that excessive subsidies might displace companies' original R&D investments, thus hindering green innovation. In light of ongoing debates regarding direct cash subsidies, the focus has shifted toward tax incentives as an indirect fiscal measure. The impact of tax incentives on green innovation has shown mixed results, with some studies indicating a positive effect while others suggest a negative impact. While there is substantial literature addressing the effects of individual policies on innovation, often measured through a single variable related to green innovation, the combined effects of both subsidies and tax incentives remain underexplored. Additionally, external financing factors are vital in a firm's R&D investment, warranting consideration of corporate financing constraints as a mediating variable. Therefore, this paper examines the influence of tax incentives on green innovation across varying subsidy levels and explores the mechanisms by which tax incentives operate.

This research utilizes data from publicly listed manufacturing companies spanning 2010 to 2019, measures the intensity of tax incentive policies using the B-index, and establishes an evaluation framework for corporate green innovation through the entropy weighting method (EWM). It investigates the effects of tax incentives on green innovation in different types of firms, as well as the mediating role of financing constraints and the moderating role of subsidies. This study is innovative in several ways: 1) Instead of employing the Difference-in-Differences (DID) approach to assess policy impacts, this paper quantifies policy effects using the B-index, thus expanding the understanding of corporate green innovation within the framework of endogenous growth theory. 2) Unlike existing research that primarily relies on singular metrics such as R&D investment or patents to evaluate corporate innovation, this paper introduces a comprehensive evaluation system for corporate green innovation, assessing performance from multiple perspectives.

The remainder of the paper is structured into four sections: theoretical analysis and hypotheses, variable description and methodology, empirical analysis with conclusions and discussion, and finally, a section outlining conclusions, insights, and limitations (refer to Figure 1)

The conversation around tax reforms to stimulate green entrepreneurship is multifaceted, encompassing economic, environmental, and social dimensions. In Russia, the potential for developing a robust green economy is significant, yet there are various challenges and opportunities to consider. This discussion examines the implications of tax reforms, the regional context, and the broader societal impact of promoting green entrepreneurship.

1. Economic Implications

Incentivizing Investment: Effective tax reforms can create a favorable environment for investors interested in green technologies. By offering tax credits, exemptions, or reduced rates for renewable energy projects, the government can encourage both domestic and foreign investments.

In a resource-rich country like Russia, tapping into renewable energy sources could reduce dependency on fossil fuels, thereby diversifying the economy.

Job Creation and Economic Diversification: Green entrepreneurship has the potential to generate new jobs, especially in regions transitioning from traditional industries. By promoting sectors such as renewable energy, energy efficiency, and waste management, tax reforms can support economic diversification, creating employment opportunities for a skilled workforce.

2. Environmental Impact

Meeting Climate Goals: Russia has committed to international climate agreements, and stimulating green entrepreneurship is essential for achieving these targets. Tax reforms can support the development of clean technologies, reducing greenhouse gas emissions and fostering sustainable practices across various sectors.

Encouraging Sustainable Practices: By implementing tax incentives for environmentally friendly business practices, the government can encourage companies to adopt sustainable methods. This could include support for energy-efficient manufacturing processes, waste reduction initiatives, and sustainable supply chain practices, contributing to overall environmental preservation.

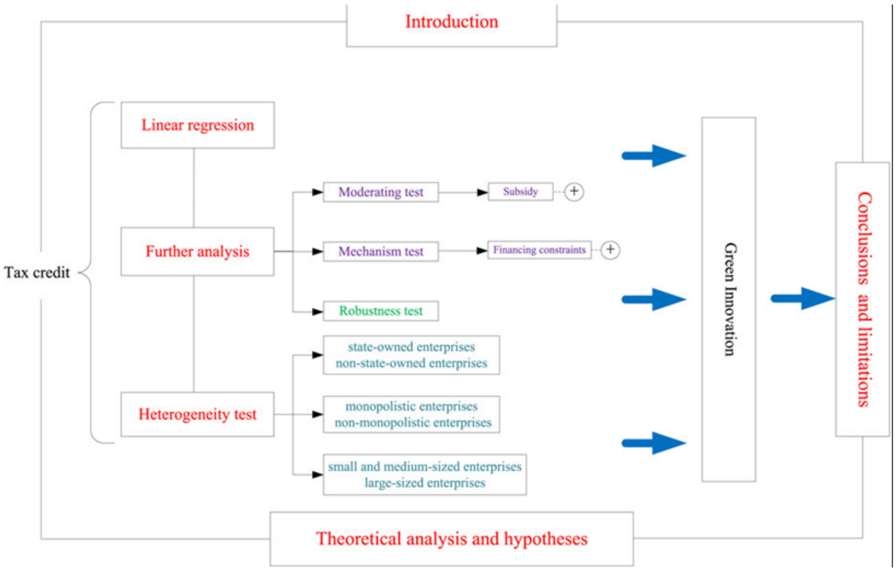

Figure 1: *Logic diagram*

IV. Discussion

3. Social Dimensions

Equity and Accessibility: While tax reforms can stimulate green entrepreneurship, it is vital to ensure that these initiatives are equitable. Small and medium enterprises (SMEs), which often lack the resources to navigate complex tax codes, should be prioritized. Simplified tax structures and targeted support can help ensure that all businesses, regardless of size, can access the benefits of green entrepreneurship.

Public Awareness and Engagement: For tax reforms to be effective, there must be public awareness and engagement regarding green entrepreneurship. Educating entrepreneurs about available incentives and the benefits of adopting sustainable practices can drive demand for green technologies and foster a culture of sustainability within the business community.

4. Challenges in Implementation

Bureaucratic Barriers: One of the significant challenges facing tax reforms in Russia is the existing bureaucratic framework. Complicated regulatory processes can deter entrepreneurs from pursuing green initiatives. Streamlining these processes and providing clear guidelines for tax incentives is crucial for encouraging participation in the green economy.

Infrastructure and Technological Gaps: The successful implementation of tax reforms to stimulate green entrepreneurship also depends on the availability of infrastructure and technology. Regions that lack adequate renewable energy infrastructure may struggle to attract investment, regardless of tax incentives. The government must invest in building the necessary infrastructure to support green initiatives.

Regional Disparities: The effectiveness of tax reforms may vary across different regions in Russia. Areas rich in natural resources may have better opportunities to develop renewable energy projects, while others may require more support and investment to foster green entrepreneurship. Policymakers should consider these regional disparities when designing tax incentives to ensure balanced development.

5. Global Comparisons and Best Practices

Learning from Global Experiences: Russia can benefit from examining global best practices in tax reforms aimed at promoting green entrepreneurship. Countries like Sweden and Germany have successfully implemented tax incentives that have led to significant advancements in renewable energy sectors. Adopting a tailored approach that considers Russia's unique context while incorporating effective strategies from other nations can enhance the effectiveness of tax reforms.

International Collaboration: Engaging with international organizations and participating in knowledge-sharing platforms can help Russia develop more effective tax policies for green entrepreneurship. Collaborative efforts can provide insights into successful case studies and innovative solutions that have been implemented elsewhere.

[3]Khetagurov North Ossetian State University, RUSSIA
vms88@inbox.ru

Abstract

In an era marked by pressing challenges such as climate change, environmental degradation, and social inequality, the influence of the human factor on the economic growth of regions and countries has become increasingly significant. Human capital, which includes not only education and skills but also health, creativity, and social cohesion, plays a pivotal role in determining the trajectory of economic development.

This paper examines the multifaceted relationship between the human factor and economic growth within the context of sustainable development, emphasizing the necessity for a holistic approach that integrates economic, social, and environmental dimensions. Human capital is a critical driver of innovation and productivity, influencing the competitiveness of economies at both regional and national levels. Regions that invest in education, vocational training, and health care are better positioned to foster skilled workforces capable of adapting to the demands of a rapidly changing global economy. Furthermore, social factors such as trust, community engagement, and cultural values significantly affect the effectiveness of economic policies and initiatives aimed at sustainable development.

This study analyzes various case studies from diverse regions, illustrating how the human factor has led to differing economic outcomes in the context of sustainable development. For example, regions that prioritize inclusive education and promote gender equality tend to experience higher levels of innovation and economic resilience. In contrast, areas with limited access to education and healthcare often struggle with persistent poverty and underdevelopment.

The paper also addresses the challenges and barriers that hinder the effective utilization of human capital, such as socioeconomic disparities, inadequate infrastructure, and a lack of supportive policies. It highlights the importance of creating environments that empower individuals and communities to contribute to sustainable economic growth.

The development of human potential is a vital component of Russia's strategic vision for the future. By focusing on education, healthcare, science and technology, social services, and regional development, the government aims to create a resilient and dynamic society capable of navigating the complexities of the modern world. However, addressing the inherent challenges and ensuring inclusive growth will be key to realizing these ambitious goals. As Russia moves forward, a holistic approach that considers the interplay of various factors will be essential in fostering sustainable human potential development and economic security.

Keywords: regional development, social aspects, ecological sustainability, policy recommendations, education, healthcare, community engagement, gender equality, socioeconomic disparities, inclusive development

I. Introduction

The relationship between the human factor and economic growth has garnered increasing attention, particularly in the context of sustainable development. Human capital—encompassing education, skills, health, and social capital—plays a pivotal role in determining a region's or country's ability to achieve economic growth while maintaining ecological balance and social equity. In an era where environmental concerns and social inequalities are at the forefront of global discourse, understanding how human factors contribute to sustainable development is essential.

Regions and countries that prioritize the development of human capital tend to experience more robust economic growth. A skilled and educated workforce not only drives innovation and productivity but also fosters adaptability in response to environmental changes and economic fluctuations. Moreover, the integration of sustainable practices into economic activities hinges on the willingness and ability of individuals and communities to embrace and implement these practices.

The influence of the human factor on economic growth manifests through various channels. First, education equips individuals with the necessary skills to engage in higher-value economic activities, leading to increased productivity. Second, health and well-being contribute to a more capable workforce, reducing absenteeism and enhancing performance. Third, social capital—characterized by networks, trust, and norms—facilitates collaboration and the sharing of knowledge, further driving innovation and growth.

However, the interplay between the human factor and sustainable development is not without challenges. Issues such as inequality in access to education and healthcare, migration, and demographic changes can hinder the potential benefits of human capital. Therefore, policies aimed at fostering human capital must also consider social inclusivity and environmental sustainability to create a holistic approach to economic growth.

In summary, recognizing and leveraging the human factor is critical for achieving sustainable economic growth. By investing in education, health, and social cohesion, regions and countries can enhance their resilience and adaptability, paving the way for a more sustainable future. This paper will explore the various dimensions of the human factor, its impact on economic growth, and the implications for sustainable development, providing a comprehensive understanding of this crucial relationship.

II. Methods

The study of the influence of the human factor on the economic growth of regions and countries in the context of sustainable development requires a comprehensive and interdisciplinary approach. The main methods used to study this problem are presented below.

1. Econometric modeling

One of the most common methods is econometric modeling, which allows you to assess the impact of various factors on economic growth. In the context of the human factor, models can be used that include the following variables:

- Education level.
- Life expectancy.
- Workforce skill level.
- Human Development Index (HDI).
- Fertility and mortality rates.

Econometric methods such as regressions, time series, and panel data help identify the relationship between human capital and economic growth.

2. Qualitative methods (interviews, focus groups)

Qualitative methods can be used to obtain in-depth data on the impact of the human factor on economic development. Interviews with experts in the field of economics, education, employment, or sustainable development provide information on practical aspects and barriers. Focus groups help to identify the opinions and expectations of different social groups.

3. Analysis of human capital indicators

Using human capital indicators such as:

- Human Development Index (HDI).
- Education index.
- Gender equality index.
- Income distribution.

Comparison of these indices with indicators of economic growth of a region or country allows for a detailed analysis of the relationship between human capital development and economic efficiency.

III. Results

The state may possess natural, technological, and financial resources, but all of this is insignificant without a highly qualified workforce and a high level of human development. In today's rapidly changing world, the importance of human capital is continually increasing. "In the era of digitalization and transformation of production processes, human capital is becoming the foundation for the development of the economy of any country" [12].

In a broad sense, human capital encompasses the abilities, knowledge, skills, intellect, and health of individuals utilized in production processes and to generate income for families and the nation as a whole.

The following types of human capital are identified in the economy:

1. **National human capital** refers to a portion of national wealth that includes intellectual, physical, and labor capabilities that aid in the economic development of the country.
2. **Organizational human capital** consists of the knowledge, skills, intellectual and professional abilities, as well as the physical and psychological well-being of personnel, utilized to achieve high performance in a specific organization.
3. **Individual human capital** comprises the knowledge, skills, health, and abilities of an individual that affect their standard of living and income.

The human capital of each country can be measured. Since 2018, the World Bank (WB) has been compiling the Human Capital Index (HCI) rankings by country. The HCI can help countries analyze problem areas in their socio-economic policies and assess their readiness to transition to a sustainable development model based on the growth of human capital.

The HCI is calculated based on three components:

- Survival;
- School life expectancy adjusted for learning outcomes;
- Health status.

The United Nations (UN) employs a different indicator to assess human development—the Human Development Index (HDI), which is a composite measure reflecting an individual's ability to lead a long and healthy life, gain knowledge, and achieve a decent standard of living.

The following factors are considered when calculating the index: health and longevity, access to education, and a decent standard of living.

The index categorizes countries into four groups based on their level of human development:

- Very high value—an index of at least 0.800;

- High value—an index of 0.700-0.799;
- Medium value—an index of 0.550-0.699;
- Low value—an index below 0.550.

In 2020, the HCI included data on health and education from 174 countries, representing 98% of the global population. According to the World Bank, Russia ranks 41st in the world HCI rankings, with an index of 0.68, or 68%. This indicates that a child born in Russia today can achieve 68% of the productivity of an adult with complete education and good health in the future. For instance, Russia's education indicators surpass those of many higher-income countries, but its health indicators fall short of the global average. The top-ranked countries in the index are Singapore (88%), Hong Kong (81%), and Japan (80%).

Furthermore, as demonstrated in other research, there is a strong positive correlation between subjective well-being (SWB) and the Environmental Protection Indicator (which covers a wide range of issues such as biodiversity, ecosystems, climate, energy, air and water pollution, agriculture, and sanitation). These findings suggest that well-being is linked to the long-term outcomes of environmental policies, even if it is not necessarily positively correlated with the short-term efforts required by these policies.

The challenge for policymakers is to overcome short-term trade-offs by decoupling improvements in human well-being from the consumption of natural resources and greenhouse gas emissions. A recent OECD report addresses this challenge by proposing climate change mitigation through a well-being perspective, placing people at the center of climate action. The countries identified in our analysis, that perform well on SDG 12 and SDG 13 while also achieving high levels of well-being suggest there may be pathways to enhancing well-being without compromising environmental sustainability. These countries include a mix of large and small nations. For instance, Germany has heavily invested in renewable energy infrastructure, creating 'green jobs' while simultaneously reducing emissions. The combination of carbon taxes, incentives for renewable energy, and ambitious social policies has enabled Nordic countries to transition away from fossil fuels without burdening low-income households with higher energy costs. Similarly, Costa Rica ranks among the top nations for investment in renewable energy relative to GDP and has committed to achieving carbon neutrality starting in 2021. It offers an alternative model for developing nations to avoid the carbon-intensive development path of the West.

According to the World Bank, human capital constitutes 64% of the world's wealth, estimated at $1,152 trillion. This highlights that human intelligence, health, and the development of professional and creative abilities—along with education—are becoming crucial resources, comparable to oil, gas, innovative technologies, and other assets of the national economy. A robust level of human capital fosters increased income, well-being, and quality of life not only for individuals but for the entire country. Therefore, "national programs should primarily focus on enhancing the education system, healthcare, and the social sector".

The contemporary world demands modern solutions. Innovations are now integral to every sector of economic activity. Currently, the advancement of high-tech industries represents a key competitive advantage for nations. According to Rosstat, there has been an increase in the contribution of these sectors to total GDP over the past decade. Consequently, producing high-tech products necessitates highly qualified professionals. As technological innovations expand within the country, the demand for human capital is set to rise accordingly.

Human development as a factor in ensuring the economic security of the EAEU countries. The Eurasian Economic Union (EAEU) is a growing integration association in the post-Soviet region, aimed at implementing a unified economic policy and facilitating the free movement of goods, services, capital, and labor resources [8]. One of its founding goals is the comprehensive development of modernization, cooperation, and enhancing the competitiveness of the member countries' economies within the global context. In today's environment, human potential has become a critical factor in ensuring the economic security of the EAEU.

An examination of population data from the EAEU countries over the last fifteen years indicates a notable rise in this metric. From the analysis of the data, several conclusions emerge. At the start of the study period (2005), Russia had the largest population, followed by Kazakhstan, Kyrgyzstan, and Belarus. Throughout this time, the population trends of these countries diverged. For instance, Russia exhibited relative stability, remaining close to its initial population level by 2020. In contrast, Kazakhstan showed positive growth, significantly increasing its population by 2020. Kyrgyzstan, however, maintained relative stability, with its population level staying near the initial figure.

Overall, the EAEU countries have experienced population growth over the past fifteen years, reaching notable increases by 2020. These developments underscore the significance of demographic factors in analyzing the region's socio-economic landscape and highlight the necessity of considering population trends when crafting development strategies.

Regarding age demographics, Russia, Belarus, and Armenia are characterized by a relatively low percentage of minors and a considerable elderly population, indicating that these nations are facing the challenges of population aging. This trend may diminish their economic and military influence, necessitating primary focus on ensuring the effectiveness of pension and healthcare systems, as the overall demographic burden on the working-age population is projected to nearly double by mid-century.

Thus, human potential plays a crucial role in all aspects of economic security, including production, food, foreign economic, and socio-demographic security, among others. Key destabilizing factors affecting human potential and economic security in the EAEU countries include significant disparities in human development and socio-demographic progress; gender inequality; increasing income disparities; and declining quality of life and well-being. Furthermore, Russia, Belarus, and Armenia continue to face issues of depopulation and aging, which directly result in a loss of labor resources.

Given the considerable challenges surrounding the levels and synchronicity of human potential development across EAEU nations, it is essential to reevaluate approaches to intra-integration interactions concerning the formation, development, implementation, and preservation of human potential. Strengthening cooperation should be prioritized, focusing on the following key areas:

1. Rapid advancement of digital transformation across all areas of human activity and society as a whole.
2. Enhancing collaboration in healthcare.
3. Emphasizing environmental sustainability in the creation of new joint projects aimed at achieving sustainable human development.
4. Boosting cooperation in education, science, and innovation.

Addressing these priorities and implementing them will enable the development of human potential, thereby ensuring a sufficient level of economic security for both individual EAEU countries and the entire Union.

Furthermore, Russia's national goals and strategic objectives for development until 2024 are supported by the national projects established in various sectors, including demography, healthcare, education, housing and urban development, ecology, safe and high-quality roads, labor productivity and employment, science, digital economy, culture, entrepreneurship, and more. These projects align with the principles outlined in the human potential development concept.

The Strategy of Economic Security of the Russian Federation identifies the development of human potential and the challenge of enhancing its quality as critical areas and significant threats to economic security in the social sphere.

The Russian government places particular emphasis on several key areas to promote the development of human potential:

1. **Education**: The Government of the Russian Federation is investing in the education system, focusing on improving the quality of primary and secondary education as well as vocational training. Additionally, there is increased funding for higher education and a push for greater international collaboration. Federal Law No. 273 establishes fundamental principles and regulations governing education in Russia, covering primary, secondary, and higher education, alongside provisions for preschool, vocational, and adult education.
2. **Healthcare**: The Government of the Russian Federation allocates funds to enhance the healthcare system, concentrating on improving medical care quality, increasing access to services, and encouraging healthy lifestyles among citizens. The government has also implemented measures to combat infectious diseases. Federal Law No. 323 outlines the fundamental principles and regulations for the healthcare system in Russia, including the organization of medical care, funding for services, and patient rights protection.
3. **Science and Technology**: The government invests in advancing science and technology, particularly focusing on fostering innovation, technology transfer, and the growth of high-tech industries. Funding for research and development is being increased, along with efforts to enhance international cooperation in this field. Federal Law No. 127 lays down the basic principles and regulations for science and innovation development in Russia, covering research funding, intellectual property protection, and the commercialization of scientific findings.
4. **Social Services**: The Russian government is committed to enhancing social services, prioritizing affordable housing, social security benefits, and assistance for those in need. Additionally, the government promotes cultural development and the preservation of Russia's cultural heritage. Federal Law No. 442 defines the key principles and regulations for social service provision in Russia, focusing on support for vulnerable groups, including the disabled and elderly, as well as affordable housing and social security.
5. **Regional Development**: The Russian government implements policies aimed at stimulating economic growth across its regions, particularly in job creation, support for small and medium-sized enterprises, and fostering regional cooperation.

In 2023, state initiatives for developing human potential in Russia will concentrate on these critical areas while also encouraging broader international cooperation.

IV. Discussion

Russia has established a comprehensive framework for its development until 2024, centered around national projects in key sectors such as demography, healthcare, education, and more. This multi-faceted approach reflects the government’s recognition of the interconnection between human potential and economic security, highlighting the importance of investing in various areas to foster sustainable growth and resilience.

Human Potential Development

The emphasis on human potential development is particularly relevant in today’s rapidly changing global landscape. By prioritizing education, healthcare, science and technology, social services, and regional development, Russia aims to enhance its human capital, which is essential for economic advancement and social stability. The government's commitment to these areas not only seeks to improve individual quality of life but also to bolster national competitiveness in an increasingly interconnected world.

Key Areas of Focus

1. **Education:** Investments in education are crucial for equipping the workforce with the necessary skills to meet the demands of the modern economy. By improving the quality

of primary, secondary, and vocational education, the government is laying the foundation for a skilled labor force that can adapt to technological advancements. The focus on higher education and international collaboration also suggests a strategic vision to foster innovation and attract global talent.

2. **Healthcare:** The enhancement of the healthcare system is vital for ensuring a healthy population capable of contributing to the economy. By improving access to medical services and promoting healthy lifestyles, the government addresses both immediate health concerns and long-term demographic challenges, such as population aging. Effective healthcare policies can significantly impact productivity and overall economic performance.

3. **Science and Technology:** Investing in science and technology is essential for driving innovation and economic diversification. By promoting research and development and protecting intellectual property, the government aims to create an environment conducive to technological advancements. This focus not only strengthens domestic industries but also positions Russia as a competitive player in the global market.

4. **Social Services:** Providing robust social services is integral to promoting social cohesion and stability. By ensuring affordable housing and support for vulnerable populations, the government addresses critical social needs that can otherwise hinder economic development. The emphasis on cultural preservation also reflects an understanding of the importance of social identity in fostering national pride and unity.

5. **Regional Development:** Stimulating economic growth in various regions is crucial for balanced national development. By supporting small and medium-sized enterprises and fostering regional cooperation, the government seeks to reduce disparities between urban and rural areas. This approach not only enhances local economies but also contributes to overall national resilience.

Challenges and Considerations

While the strategic objectives set forth by the Russian government are ambitious, several challenges may impede their successful implementation:

- Resource Allocation: Ensuring adequate funding and resources for these initiatives may pose difficulties, especially in times of economic uncertainty or budget constraints. Prioritizing investments will be crucial for achieving desired outcomes.
- Social Inequalities: Addressing social inequalities and ensuring that all populations benefit from development efforts will be essential. Failing to do so could lead to social unrest and undermine national unity.
- International Collaboration: Strengthening international cooperation can bring about opportunities for knowledge exchange and technological advancements. However, geopolitical tensions may hinder collaborative efforts, particularly in science and technology.
- Demographic Trends: Russia faces demographic challenges, including an aging population and declining birth rates. Addressing these trends will require comprehensive policies that encompass family support, immigration, and workforce development.

The development of human potential is a vital component of Russia's strategic vision for the future. By focusing on education, healthcare, science and technology, social services, and regional development, the government aims to create a resilient and dynamic society capable of navigating the complexities of the modern world. However, addressing the inherent challenges and ensuring inclusive growth will be key to realizing these ambitious goals. As Russia moves forward, a holistic approach that considers the interplay of various factors will be essential in fostering sustainable human potential development and economic security.

Abstract

In many countries, the deepening of the environmental problem and the increase of anthropogenic effects on the ecosystem makes it necessary to review the basics of traditional farming and transition to an ecologically oriented economy. This development is also strategically important in our country, so an unsoiled environment and "green" growth must be accepted as national priorities. In this paper, the characteristics of the green economy are studied, and the necessity of extension of the green economy is justified. The contemporary state of "green" evolution was clarified using the example of Azerbaijan's agro-food complex, and scientific reasons for ulterior progress in this domain were given. This research also displays the gravity of applying marketing concepts when producing eco-friendly agriculture and food products. The study shows that the provision of development under the condition of expecting the interests of consumers, businesses, and society applies the socio-ethical concept of marketing. The article clarified the ecological quality of life and the economy's environmental and resource efficiency. The factors of the transition of the country's economy to "green" development tracks have been clarified. This article also tested the hypothesis that an increase in energy resource prices during the energy crisis entailed, in the short term, an increase in the share of renewables combustible in net electricity production in Europe. The study proved that the energy crisis is not an obstacle to the development of both green energy and the green economy. Based on the study's results, stages of transition to green development were elaborated to ensure eco-friendly agricultural production.

Keywords: green economy, green development, greening, environmental efficiency of the economy, resource efficiency

I. Introduction

The problems faced by our civilization in the present period led to severe changes in almost all spheres of society's life activity. These problems include global climate change, loss or disappearance of biodiversity, economic and social tensions, and the emergence and spread of viral infections. Recently, among the listed problems, the effects of virus infections on society and economic development have been more significant. However, implementing purposeful measures to solve the mentioned problem has made it feasible to reduce its effects on society significantly (Rakhmanov et al., 2020). We observe this situation in the example of our country.

However, among the global issues, solving the environmental problem remains relevant in many countries, and there is the potential to achieve stable economic and social development by solving this problem. To ensure stable economic growth, all sectors of the economy must be constantly improved. At the same time, every sector of the economy depends on the resource extraction industry. Transitioning to a green economy is one rational way out of this situation. *First of all, to ensure food security and the lasting development of the agro-food complex, it is necessary to focus on the agro-industrial complex and green energy during the transition to a green economy.*

Research shows that solving an environmental problem would take a long time. Our country's transition to a "green" economic development model will benefit society and is a reliable way to achieve persistent economic development.

In the current conditions, the world's countries are looking for ways to achieve sustainable development and try to implement it. The concept of lasting development is a qualitatively new approach from a socio-economic and ecological point of view, and it combines the following three main problems:

- The lasting development of the economy must correspond to the environmental system of people's life support.
- Rational and fair distribution of current natural resources (including energy resources) and material opportunities should be provided for the current generations and future generations.
- Natural capital should be equally distributed in society, and the needs of social groups should be met (Unesco, 2022).

The concept of lasting development is based on two main principles:

1. Humanity can give development a sustainable character for its long-term well-being.
2. Without creating conditions for realizing everyone has a better life in the future, lasting development is simply impossible. Poverty is one of the leading causes of ecological and other disasters, and it has become a common phenomenon worldwide. Therefore, poverty alleviation is one of the main tasks (State Statistics Committee, 2023).

Scholar studies show that applying the Green Economy (GE) model is necessary for contemporary conditions to move to lasting development in our territories (Vukovich, 2018). The GE model has attracted the attention of scientists and international organizations as an essential tool for realizing lasting development. For this reason, in 2012, most countries switched to a GE model at the UN conference dedicated to lasting development (RIO-20). The countries that are the main initiators of programs related to the GE, which should be especially mentioned, are Australia, Denmark, Germany, Israel, Norway, Spain, Sweden, etc.

This study relates to interdisciplinary research. Its research subject is green economic development. The main goal is identifying how the Azerbaijani economy should transition to "green" development to ensure environmentally friendly agricultural production. When setting specific objectives, the authors did not limit themselves only to studying the green development of the agro-food complex but also tested the hypothesis of whether the energy crisis led to an increase in the share of green energy in net electricity production. Thus, crises are not always an obstacle to developing a green economy.

II. Literature review

As defined by the United Nations Environment Program (UNEP), the green economy covers economic growth, environmental sustainability, and social justice (UNEP, 2011). However, there are contradictions between all three to one degree or another. Firstly, all three aspects require investment. Nevertheless, the budget of no country, even the most developed and prosperous, can provide funding in the required volumes. Each state sets the investment volume for each listed purpose, considering the opportunity cost.

Secondly, there are contradictions between economic growth and environmental stability since economic growth requires increased use of natural resources, which are mainly exhaustible.

Not only is the world's population growing, but so are their needs. An increase in demand leads to an increase in supply. The expansion of production leads to the release of pollutants and contributes to global climate change, which harms not only nature but also humans. That is, on the one hand, social justice can be ensured by economic growth. On the other hand, economic growth and expansion of production leave a carbon footprint, leading to an increase in emissions of carbon dioxide and other greenhouse gases.

Although contradictions exist, they can be mitigated with well-thought-out policies and government strategies. However, it is impossible to minimize the described contradictions without investment. Table 1 presents the main approaches to the green economy, which involve minimizing the described contradictions but have their own disadvantages.

Table 1: *Main characteristics of fundamental theories of green economy and their disadvantages*

Fundamental theories of green economy	**Main characteristics**	**Disadvantages**
Circular economy theory	In a circular economy, resources are reused and recycled to minimize waste and pollution.	The high costs of transitioning to a circular economy require significant investments. Repeated recycling of materials can decrease quality. Not all materials can be recycled. It is not economically feasible for manufacturers to produce products with a long service life.
Theory of sustainable development	Sustainable development of the national economy ensures a balance between economic growth, social inclusion, and environmental protection.	There is a high level of investment in renewable energy sources. New expensive technologies and equipment with a long payback period must be introduced. High costs can lead to decreased competitiveness, which is not profitable for entrepreneurs.
Ecological Economics	According to this theory, the economy should be a subsystem of the ecosystem.	Significant investments are needed to implement the green economy. It is difficult to achieve an economic model that considers all environmental and social factors, and there is a conflict of interest between business and environmental protection.
Theory of sustainable consumption and production	The essence of this theory is to change consumption and production patterns to reduce the negative impact on the environment.	Changing the consumption and production model may encounter the following obstacles: significant financial investments beyond the reach of small businesses, consumers' reluctance to change their habits and preferences, and the lack of green technologies in some industries.
Bioeconomy	Bioeconomy involves transitioning from fossil resources to renewable biological resources and developing biotechnology.	Biological resources are limited, leading to increased competition for their use. The development of the bioeconomy is impossible without significant financial investments. At the same time, some bioeconomic activities' economic efficiency is lower than traditional ones, which will decrease competitiveness.
Ecological modernization theory	According to this theory, environmental problems can be solved through innovation, reform, and institutional changes that do not impede economic development.	One of the assumptions of this theory is that economic growth and environmental sustainability can coexist and complement each other. However, limited natural resources indicate the opposite and are a prerequisite for reducing overall consumption.

Source: Authors' systematization.

Modern society is a society of consumers, so difficulties arise when promoting a circular economy (Figge et al., 2022). Consumers should change their habits, use the same product for a long time, and not regularly change, for example, phones and other electronics. Great difficulties will arise when manufacturers reformat since they are not interested in producing goods with a long service life. For example, if the light bulbs do not burn out regularly, and if we do not offer consumers new versions of iPhones, how can manufacturers generate revenues in volumes that would provide them with the wealth they strive for? An entrepreneur is not an altruist. Another disadvantage of the circular economy is that there are technological limitations since not all materials can be reused or easily recycled, or there are restrictions on the number of recycling cycles.

Reformatting producers is also necessary to promote sustainable development (green economy) (Ogryzek, 2023). Some sustainable technologies are less cost-effective, making them less attractive to entrepreneurs. Less efficiency combined with high costs makes production less competitive.

The main characteristics of ecological economics are sustainable resource management and the consideration of natural capital, environmental, and social factors in the economic model (Omer, 2023). Introducing environmental technologies often increases costs, which decreases revenues and profits. Thus, businesses are not interested in promoting ecological economics.

Promoting sustainable consumption and production may cause conflicts between economic, environmental, and social goals. For a massive transition of the population and business to sustainable consumption and production, the state must introduce a system of economic incentives (Goel & Baral, 2023). However, not all states can subsidize all enterprises to ensure the transition to sustainable production.

The main goal of the bioeconomy is the transition to using biological resources to produce products and services (Pan, 2023). As shown in Table 1, the limited availability of biological resources leads to increased competition for their possession and use, negatively affecting food security. It also leads to their intensive use, which can lead to monoculture practices and biodiversity loss.

The connection with green energy can be traced with all six theories listed in Table 1. Green energy is a crucial component of sustainable development.

The concept of a “green” economy is based on the awareness that all sectors of the national economy must rationally use natural resources, including energy. Thus, the green economy cannot be isolated from “green” energy. However, the research subject in most modern scientific works is either a “green” economy or a “green” energy.

The researcher M.V. Chkhan notes that the “green” economy (GE) is closely related to lasting production, consumption, energy efficiency, and renewable energy sources, which creates new jobs and improves people's well-being (Chkhan, 2021). This new economic concept, the GE, aims to unlock the value of people and nature and improve the population's well-being (Zenchanka et al., 2015). Poverty reduction and efficient and optimal use of limited natural resources form the basis of this concept (State Statistics Committee, 2022).

Researcher N. A. Khutorova believes that “green growth is a new vector of economic development,” which indicates the close interrelation of the country’s national priorities. “The GE must be viewed in continuous connection with the concept of lasting development of national and global economies” (Khutorova, 2015).

Numerous factors of green growth can be studied in more detail. Russian economists S.N. Bobylev, P.A. Kiryushin, and O.B. Kudryavtseva determine the factors of GE and lasting development within the framework of interaction between the state, society, and business and divide these factors into three categories (Bobylev et al., 2019). As E.B. Dorina and T.V. Bukhovets noted, these three factors relate to the state, society, and business (Dorina et al., 2017).

The specialized literature offers many approaches to the GE, which is oriented towards sustainable development. Some scholars argue that GE is based on transitioning to alternative resources and focuses on renewable energy sources (Gainsborough, 2018).

When studying green energy, one cannot ignore the mechanisms of energy price formation. Thus, researcher T. Gutium believes that gas pricing mechanisms influence the development of green energy, especially in periods when fossil fuel prices change considerably (Gutium, 2021). That is why this article tested the hypothesis that rising energy prices during the energy crisis led to an increased share of renewable fuels in net electricity production in Europe in the short term.

Summarizing all of the above, the authors in this study examined the "green" economy, not in isolation from "green" energy.

III. Materials and methods

This research's sources are scientific works published in the last ten years, national economic development programs, and a database of available data since 2010. The authors used the following methods: scientific abstraction, induction and deduction, static and dynamic analysis, and correlation and regression analysis. The hypothesis about the influence of energy resource prices on the share of renewable energy resources in electricity production during the energy crisis was tested using the software EViews 9.5.

EViews is a statistical package primarily used to analyze time series econometric data and build regression models. With its help, it will be proven or disproved that a significant increase in the price of energy resources leads to the growth of green energy. This package will also test the quality of the obtained regression equation.

To verify the quality of the obtained regression equation, the researchers rely on the following statistical tests: the coefficient of determination (R-squared), the coefficient of determination adjusted (Adjusted R Square), the F-statistic, Akaike Information Criterion (AIC), and Schwarz Criterion (SC).

Residuals checking for autocorrelation was performed using the Durbin-Watson Statistic test (d):

$$d = \frac{\sum_{i=2}^{n}(\xi_i - \xi_{i-1})^2}{\sum_{i=1}^{n}\xi_i^2} \tag{1}$$

$$\xi_i = y_i - \widehat{y_i} \tag{2}$$

Where:

ξ_i – random member with "statistical noise" properties ("White noise" - time series with zero expectation),

y_i – the value of the endogenous variable,

$\widehat{y_i}$ – the adjusted value, obtained with the regression equation.

Depending on the value obtained, we can highlight the following general cases:

if d=0, then there is perfect positive autocorrelation;

if d=4, then there is perfect negative autocorrelation;

If d≈2, we consider the deviation from the regression line to be random. This means that the constructed linear regression probably reflects the actual dependence.

The Breusch-Pagan-Godfrey test was used to check the heteroscedasticity of the residuals. The number of observations is 24. The observations represent monthly data for the years 2021-2022.

IV. Results

Recently, the concept of GE has been increasingly used in the scientific community. "The GE is no longer a new concept; it is used to explain a particular type of economic development, and at this time, the main goal is to improve the material well-being of people with the expectation of social justice and the reduction of anthropogenic impacts on the ecosystem (Khutorova, 2015).

Our country has no universally accepted and unambiguous definition of a GE. We do not observe that this concept is defined explicitly in the normative documents of the Republic of Azerbaijan. The most comprehensive description of this concept appears in the UN Environment Program. According to this document, the GE model is an economy that ensures a decent standard of living for people while protecting the environment without creating risks for future generations.

The deepening of environmental problems worldwide and the anthropogenic effects on ecosystems are reaching a dangerous level, making it necessary to review the foundations of traditional farming and transition to an ecologically oriented economy. "Economic growth is constantly creating unwanted and dangerous changes on our planet. The main reason is that carbon-based fuel products are the main energy resources to ensure economic development worldwide" (Gasimli et al., 2022). The type of ecologically oriented economy is called GE. The complex transformation strategy for a GE is called "green growth." Preserving ecological balance and improving the environment is impossible without "green" economic development. In this regard, "green development" is the most important means of lasting development.

In the document "Azerbaijan 2030: National Priorities for Socio-economic Development," adopted by the Decree of the President of the country on February 2, 2021, a lasting, growing, competitive economy, a clean environment, and a country of "green" growth were accepted as national priorities in our country. Until now, specific work has been done to transition our country's economy to green development tracks, and these measures are continuous. As a result of these measures, reductions in the volume of pollutants released into the atmosphere and significant improvements in some indicators characterizing the ecological quality of life are observed in our country.

As can be seen from the statistical analysis, the volume of pollutants released into the atmosphere from stationary sources in 2022 decreased from 170.9 thousand tons to 158.4 thousand tons, or by 7.3%, compared to 2018. During the analyzed years, the volume of pollutants released into the atmosphere from mobile sources decreased from 950.2 thousand tons to 772.2 thousand tons (18.7%) (Figure 1).

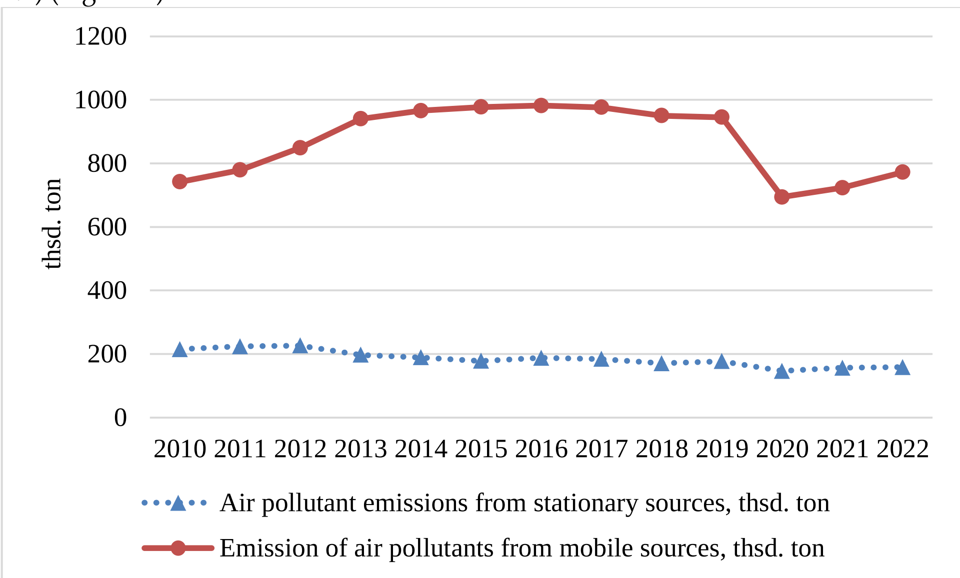

Figure 1: *Evolution of air pollutant emissions*
Source: The State Statistical Committee of the Republic of Azerbaijan

Currently, special attention is paid to developing the "green" agro-food complex to improve the quality of life in our country. To ensure the green development of the said complex, specific works have been done to create a legal framework and form its institutional foundations. Thus, the laws of the Republic of Azerbaijan "On ecological agriculture," "On food products," and "On the protection of consumers' rights" were adopted, and the Food Safety Agency was established.

In addition to all this, ensuring the coordination of activities on the production of ecologically clean agricultural products, expanding social and economic incentive measures that will help the development of the environmentally clean agricultural system, organizing fairs for producers of these products, and creating a product certification mechanism, the production of ecologically clean products it is planned to multiply and increase the number of people engaged in the production of these products by 50%.

These measures stipulated in the "Strategic Roadmap for the Production and Processing of Agricultural Products" have been almost implemented. As a result, the ecologically clean agricultural products market has developed to some extent as one of the critical segments of the food market. The research shows that specific improvements in some ecological and economic indicators in agriculture, forestry, and fishing (for example, reduction of wastewater discharge into surface water bodies, prevention of water loss used for irrigation, etc.) increase to a certain extent.

These opportunities can facilitate the growth of environmentally friendly products in domestic and foreign markets. The capacity of ecologically clean agricultural and food products is increasing yearly, and these products are among the dynamically developing markets. Thus, research shows that between 2000 and 2019, sales of organic agricultural products worldwide increased more than sevenfold. According to experts in this field, the market's growth for environmentally friendly products will continue from year to year, and in 2025, the volume of this market will reach 212-230 billion dollars. This means up to approximately 5% of the capacity of the world agricultural and food products market in terms of value.

The number of people who prefer organic products in the farming and food market worldwide is constantly increasing. The number of consumers of these products has increased approximately four times between 2005 and 2020, exceeding 700 million. According to data from the last few years, Switzerland is the leader among the countries that spend the most on organic products. Thus, in this country, the expenses incurred for acquiring organic products per person during the year amounted to 210 euros. This indicator was equal to 163 euros for Denmark, 157 euros for Luxembourg, 129 euros for Liechtenstein, 127 euros for Austria, 106 euros for Sweden, 93 euros for Germany, 77 euros for the USA, 71 euros for Canada, and 44 euros for Norway. The United States is the leader in terms of the capacity of the organic products market (44.7 billion euros). Germany ranks second, and France is third.

The production of these products and the actual capacity of the organic products market are expected to increase. Therefore, it is essential to focus on improving the production of these products, which also means raising the standard of living and preserving the national gene pool. Considering what has been said, attention to the production of environmentally friendly products has increased in recent years in our country.

In Azerbaijan, ecologically clean products are produced and offered to the market, which are directly consumed without processing, as well as those that undergo deep processing. These products include grapes, vegetables, subtropical plants, pasta, rice, milk, dairy products produced on family farms, and honey. These products offered to the market are positioned in the eyes of their buyers as ecologically clean products compared to products made traditionally, leading to buyers' preference for those products, thus ensuring their high competitiveness. Unfortunately, there is no accurate information on the listed products' production volume. Therefore, analyzing the conjuncture of ecological agriculture and food products is tricky.

Through market observation, it is possible to get a specific idea about the sale of the listed products and the buyers' satisfaction (Gutium et al., 2023). All this shows that the market of ecologically clean agriculture and food products in our country is experiencing its formation period. In addition to the so-called growth of the production of organic products in our country, it can allow the development of the export of those products and increase the profitability level of producers. This is because organic agricultural and food products are several times more expensive than conventionally produced products of the same name. Indeed, the costs involved in making these products are also high. Still, the income from the sale of the products allows them to cover the costs and ensure the necessary level of profitability for the producers. From this point of view, foreign organic agricultural and food products markets are pretty attractive for producers. Several principles must be observed in the production process for product development for those markets.

The document "Concept on the restoration and development of the liberated territories of the Republic of Azerbaijan" was prepared to realize the economic potential of the region based on the methodological approaches and advanced international practices on the restoration and reconstruction of the territories from Karabakh, ensuring lasting development in these territories (Gasimli et al., 2022). This document defines the principles of keeping the territory restoration process in focus. These principles are as follows:

- Achieving high population density when returning to restored areas;
- Involvement of private and state, as well as local and foreign investments in the recovery process to reduce state costs, in particular, wide use of public and private sector partnership;
- The process of restoration of territories consists in creating more demand for new production and thus stimulating the growth of the country's economy.

The principles mentioned above, in turn, envisage the preparation and implementation of political measures, including complex programs, related to the territories' restoration, reconstruction, and lasting development.

As noted above, organic agricultural and food products are several times more expensive than traditional analog products. Rising energy prices can become an obstacle to developing a green economy. However, as we will prove below, the energy crisis has led to the growth of green energy, which is an integral part of the green economy. So, the crisis is not an obstacle to developing both "green" energy and the "green" economy.

A regression analysis method was used to test the hypothesis about the influence of world natural gas and oil prices in Europe on the share of green energy in electricity production during the energy crisis. As a result, the following regression equation was developed using the software EViews 9.5:

$$\ln(share_{green}) = 2 - 0.1 \times \ln(price_{gas}) + 0.43 \times \ln(price_{oil}) + 0.13 \times d05 - 0.12 \times d11. \quad (3)$$

Where:

$share_{green}$ – the share of green energy in electricity production in Europe;

$price_{gas}$ – the natural gas price in Europe;

$price_{oil}$ – the oil price in Europe;

$d05$, $d11$ – dummy variables (05 – value "1" for May 2021; 11 – value "1" for November 2021).

The results of testing the null hypothesis H0 according to which the regression parameters of the regression equation (3) are equal to zero is presented in Table 2.

Table 2: *Testing the null hypothesis H0 that the regression parameters are equal to zero*

Variable	standard error	t-statistic	p-value
C	0.285909	7.066672	0.0000
$\ln(price_{gas})$	0.022222	-4.548545	0.0002
$\ln(price_{oil})$	0.076330	5.625145	0.0000
$d05$	0.049024	2.577127	0.0185
$d11$	0.047761	-2.591611	0.0179

Source: Authors' estimation using EViews 9.

The quality of regression equation (3) was verified, and the results are presented in Table 3.

Table 3: *The results of testing the quality of the regression equation*

Statistical tests	Value
R-squared	0.730786
Prob(F-statistic)	0.000031

Durbin-Watson statistic	2.1720
Akaike info criterion	-3.126022
Schwarz criterion	-2.880594
Hannan-Quinn criterion	-3.060910

Source: Authors' estimation using EViews 9.

The residuals do not autocorrelate according to the value of the Durbin-Watson statistic. The Breusch-Pagan-Godfrey test results showed that the regressions' random residuals are homoscedastic (Table 4).

Table 4: *Results of the Breusch-Pagan-Godfrey test*

	Value
F-statistic	0.6395
Obs *R-squared	2.8477
Scaled explained SS	2.4490
Prob. F (4,19)	0.6408
Prob. Chi-Square (4)	0.5836
Prob. Chi-Square (4)	0.6538

Source: Authors' estimation using EViews 9.

The obtained result indicates that only the price of oil had a direct positive impact (in the short term) on the share of green energy during the energy crisis in Europe. However, according to previous studies (Gutium, 2022), the price of natural gas directly impacts the share of green energy in energy-importing countries in the long term. The found cause-and-effect relationship shows that developing one's green energy is necessary to reduce the impact of volatility in world energy prices.

V. Discussion

The International Federation of Organic Agriculture (IFOAM) has defined the following principles that must be followed during the production of organic agricultural products: principles of ecology, health, care, and fairness. Many world countries have adopted the listed principles, and according to the latest information, their number has exceeded 180. The area of land devoted to organic farming in these countries has also increased yearly and, according to 2019, was equal to 72.3 million hectares.

In the last twenty years, the area of land certified for producing environmentally friendly products has increased up to seven times. Australia has the leading position worldwide in terms of cultivated area devoted to making organic products (35.7 million hectares). The following places are occupied by Argentina and Spain (respectively 3.7 and 2.4 million ha). According to 2020 data, the number of organic product producers worldwide is 3.1 million. Studies show that the area allocated for organic product production in Azerbaijan is 0.8% of the total land area. It should be noted that the level of this indicator varies around 1.5-1.6% worldwide.

Organic products produced in our country are rarely found in large trade networks. In trade networks of foreign countries (Russia, Belarus, etc.) are observed more on imported organic food products (for example, pasta products, cereals, etc.). This is because local producers establish relationships with consumers directly through social networks. This in itself should be considered admirable. Thus, forming relations with these products' direct consumers means removing intermediaries from the sales channel. In this case, the prices of the products become fairer, satisfying both producers and consumers.

In addition to all this, direct sales of products allow producers to have more income and, therefore, more efficient market operations than the intermediary sales channel. This essential factor encourages the development of the organic products market. However, in the future, the formation of a multi-channel system of organic products in our country will be inevitable. This will allow product manufacturers to increase the channel selection opportunities in product realization and to realize their products on the desired channel. Direct and indirect sales channels of organic products are active in developed foreign countries. It should also be noted that most of the products produced in those countries are sold through indirect sales channels. So, for example, according to data from recent years, 90% of organic products in Denmark, 72.3% in Great Britain, 54.0% in the USA, and 50% in Russia are sold through supermarkets.

Specialized stores are selling organic products in the listed countries. In these countries, the sale of products made by Denmark through specialized stores accounts for around 4% of the total volume of organic products. The mentioned indicator is 12% in France, 13.5% in Italy, 15% in Great Britain, and 25% in neighboring Russia. The high level of organization in the sale of organic products in the extensive trade networks of our country requires paying attention to solving the issues related to the marketing of these products. This is because, in the conditions of market relations, the competition between products and enterprises is based on marketing factors. Among these factors, packaging and certification of products at a level that can appeal to the consumer's taste in the current conditions can lead to the preference of those products compared to competing products and, thus, to the strengthening of the market positions of local producers.

In general, to ensure "green" development in the agro-food complex, it is necessary to apply the social-ethical marketing concept of marketing by business structures operating in this complex. During the application of this concept, not only the interests of consumers (this is ensured by offering consumers environmentally friendly products) but also producers (the interests of the manufacturing enterprise are manifested by obtaining sufficient profit to continue its market activity, and this is justified for the long-term period) and society as a whole interest (which manifests itself in the form of prevention of pollution of the environment and thus preservation of ecological balance) is protected.

Thus, lasting development is ensured. Transferring our country's development to the tracks of "green development" does not end with the measures mentioned above. The construction works in Karabakh are being implemented based on the principles of green development. We believe implementing intelligent village and city projects in Karabakh will significantly contribute to development based on the GE model.

The transition to "green" development to ensure environmentally friendly agricultural production requires an integrated approach, including the stages presented in Figure 2.

Figure 2: *Stages of transition to green development to ensure environmentally friendly agricultural production*
Source: Authors' elaboration

The passage of all these stages helps Azerbaijan create a sustainable and environmentally friendly agricultural complex that protects the environment, improves product quality, and improves the well-being of the rural population.

VI. Conclusion

The green economy theories examined in this study reflect a scientific approach to sustainable development that considers economic, environmental, and social factors. None of the theories is perfect; each has shortcomings. The main disadvantages are high initial costs and resistance from businesses due to the risk of reducing profits and competitiveness of production. All these obstacles can be overcome provided the state subsidizes the transition to a green economy and develops and applies a system of economic incentives.

The GE is interpreted as a concept that provides environmental sustainability, production and consumption of products and services, and investments in green development. When this issue is approached from a philosophical-sociological point of view, socio-economic development, income growth, employment, and poverty reduction are considered while ensuring environmental sustainability. There is no well-defined and universally accepted definition of what the concept of GE covers. For this reason, different countries come up with various definitions within their specific conditions. In fact, in the current conditions, the understanding of the GE, its scientific definition, and social-philosophical investigation differ in different countries.

Because the degree of socio-economic development of different countries is different, for example, there is considerable variation in lasting development between developed, developing, and newly industrialized countries. These differences are also reflected in the respective countries' GE levels and the steps taken in this direction.

In our opinion, the following can be attributed to the main ways of moving Azerbaijan's economy to the tracks of "green development":

- reducing the energy capacity of the economy (this can be achieved by reducing the share of non-productive sectors of the economy),
- extensive use of non-traditional energy resources, including renewable energy resources (solar, wind energy),
- reduction of anthropogenic (related to human activity) impacts of the energy sector on the environment,
- improvement of normative legal documents in the field of GE,
- create an efficient system of personnel training in energy-saving technologies, etc.

Factors related to society include the formation of an ecological lifestyle culture, the development of eco-activism, and the popularization of the eco-volunteer movement. Factors related to the state include the need for modernization of the economy, international cooperation in the sphere of lasting development, the implementation of internationally essential state projects, and the expectation of lasting development in the development of cities from an ecological point of view. Finally, factors related to business include improvement of environmental regulation, detection of "green" opportunities for business, and norms and standards for lasting development in business management.

In addition to the above, green economic development is influenced by using new and advanced technologies and actualizing environmental problems. To achieve this goal, factors affecting green economic development should be considered in a complex and systematic manner, thus ensuring lasting development.

Abstract

This paper investigates the integration of behavioral economics into sustainability efforts, highlighting the critical role that human incentives play in promoting green growth strategies. As environmental challenges escalate globally, understanding the psychological mechanisms driving individual and collective decision-making becomes essential for crafting effective policies. The research identifies key behavioral insights, such as cognitive biases, heuristics, and the influence of social norms, which can be harnessed to encourage sustainable practices. It emphasizes the importance of designing interventions, including nudges and economic incentives, that align with human behavior to foster environmentally friendly actions among individuals and businesses. Through the examination of various case studies, the paper showcases successful implementations of behavioral interventions that have led to measurable improvements in sustainability outcomes. Ultimately, this study aims to equip policymakers and practitioners with practical tools and strategies to enhance the effectiveness of green growth initiatives, ensuring that they resonate with human behaviors and contribute to long-term sustainable development goals.

Keywords: behavioral economics, sustainability, green growth, human incentives, environmental policies, decision-making, nudges, social norms

I. Introduction

In recent years, the urgency of addressing climate change and environmental degradation has gained unprecedented global attention. As governments and organizations seek to implement strategies for sustainable development, the challenge of aligning human behavior with green growth objectives has become increasingly apparent. Traditional economic models often overlook the complexities of human decision-making, leading to policies that fail to engage individuals effectively in sustainability efforts.

Behavioral economics provides valuable insights into the cognitive biases, heuristics, and social influences that shape human choices. By understanding these psychological factors, policymakers can design interventions that motivate individuals and businesses to adopt environmentally friendly practices. For instance, simple nudges—subtle changes in the way choices are presented—can significantly impact behavior, such as encouraging recycling or energy conservation.

Moreover, the concept of aligning incentives is critical for fostering a culture of sustainability. Economic incentives, educational initiatives, and community engagement strategies can work synergistically to promote green behaviors. This approach recognizes that humans are not solely driven by rational calculations; social norms, values, and emotional connections also play crucial roles in decision-making.

This paper explores the intersection of behavioral economics and sustainability, highlighting the potential for aligning human incentives with green growth strategies. It aims to provide an in-depth analysis of how behavioral insights can inform policy design, enhance individual and collective actions, and ultimately contribute to a more sustainable future. By examining successful case studies and effective interventions, this research seeks to equip policymakers, businesses, and communities with actionable strategies that foster sustainable development and combat the pressing environmental challenges of our time.

The following sections will outline the key principles of behavioral economics, discuss their application in sustainability contexts, and propose recommendations for integrating these insights into green growth strategies.

II. Methods

This study employs a mixed-methods approach to explore the intersection of behavioral economics and sustainability, focusing on how human incentives can be aligned with green growth strategies. The methods are designed to gather quantitative data and qualitative insights, enabling a comprehensive understanding of the behavioral factors influencing sustainability practices.

1. Literature Review

An extensive literature review was conducted to establish a theoretical foundation for the study. This review encompasses scholarly articles, books, and case studies related to behavioral economics, sustainability, and green growth strategies. The review aims to identify key concepts, frameworks, and existing interventions that illustrate the application of behavioral insights in promoting sustainable behaviors.

2. Quantitative Analysis

Quantitative data were collected through surveys distributed to a diverse sample of individuals and businesses across various sectors. The survey aimed to assess attitudes toward sustainability, perceived barriers to adopting green practices, and the effectiveness of different incentives (e.g., financial rewards, educational campaigns) in promoting eco-friendly behaviors. Key metrics included:

- Behavioral Intentions: Measures of participants' intentions to engage in sustainable practices, such as recycling, energy conservation, and sustainable consumption.
- Perceived Effectiveness: Ratings of how effective participants believe different incentives and nudges are in influencing their behaviors.
- Demographic Variables: Data on participants' age, gender, education level, and geographic location to analyze potential differences in attitudes and behaviors.

Statistical methods, including regression analysis and correlation tests, were employed to identify relationships between variables and assess the impact of incentives on sustainable behaviors.

3. Qualitative Case Studies

In-depth qualitative case studies were conducted to explore successful implementations of behavioral interventions aimed at promoting sustainability. These case studies involved:

- Interviews: Semi-structured interviews with key stakeholders, including policymakers, business leaders, and community organizers, to gain insights into the design, implementation, and outcomes of specific initiatives.
- Document Analysis: Review of program materials, reports, and evaluations related to the selected case studies to gather contextual information and assess effectiveness.

The qualitative data were analyzed using thematic analysis to identify common themes, challenges, and best practices associated with behavioral interventions in sustainability.

4. Integrative Framework Development

Based on the findings from both quantitative and qualitative analyses, an integrative framework was developed to guide policymakers and practitioners in aligning human incentives with green growth strategies. This framework synthesizes behavioral economics principles, effective interventions, and actionable recommendations tailored to various contexts and stakeholder groups.

Summary

The combination of literature review, quantitative analysis, qualitative case studies, and integrative framework development provides a robust methodology for examining the complex relationship between human behavior and sustainability. By leveraging insights from behavioral economics, this study aims to contribute to the design of effective green growth strategies that resonate with individuals and promote a culture of sustainability.

III. Results

Human impact on the planet has been tremendous since the last century, leading to a 60% loss in global biodiversity. The mid-twentieth century's Great Acceleration of unsustainable growth marked the onset of a new geological era known as the Anthropocene, characterized by rapid increases in population, production, consumption, greenhouse gas emissions, waste, and pressure on ecosystems. Research indicates that as the global middle class expands, climate change and resource scarcity pose urgent threats that necessitate changes in individual consumption patterns, such as reducing fossil fuel use and meat demand (see Appendix – Case Study: Reducing Meat Consumption in Developed Countries).

To achieve green growth, policies should incentivize more sustainable consumption and production behaviors. Policies that positively influence everyday behaviors and social norms are crucial in decoupling economic growth and human well-being from their detrimental effects on the environment. Insights gained from observation and experimentation in behavioral and social sciences—such as psychology, cognitive science, neuroscience, and organizational behavior—provide powerful guidance for designing impactful and cost-effective green growth policies aligned with human decision-making.

Human behavior has various dimensions, dynamics, and drivers at all levels of the economy. At the microeconomic level, this encompasses individuals, households, and communities. At the meso and macro levels, organizational actors, such as governments and corporations, shape the choice architecture for citizens, employees, and consumers.

Green growth policy frameworks need to be more informed by behavioral insights. Currently, these policies are formulated under the assumption that citizens act rationally. However, advancements in behavioral sciences have illuminated the complexities of human decision-making, introducing concepts such as "bounded rationality" and "information-processing biases." Policies that acknowledge the limits of rationality can facilitate a shift in behaviors and societal norms toward green growth.

Behavioral science has made significant strides in analyzing and crafting behaviorally-informed policies. Today, governments from the United Kingdom to Singapore and Colombia are incorporating behavioral insights into their policymaking to find cost-effective solutions to governance challenges. Achieving the targets set out in the 17 Sustainable Development Goals (SDGs) and the Paris Agreement on Climate Change cannot occur without incentivizing sustainable behaviors and attitudes at scale.

IV. Discussion

The factors influencing green growth behavior can be examined across various levels (see Fig. 1). At the microeconomic level, research typically focuses on individuals, households, communities, small and medium-sized enterprises, and local governments. Meanwhile, the meso and macroeconomic levels encompass organizations such as economic sectors, large corporations, and provincial and national governments.

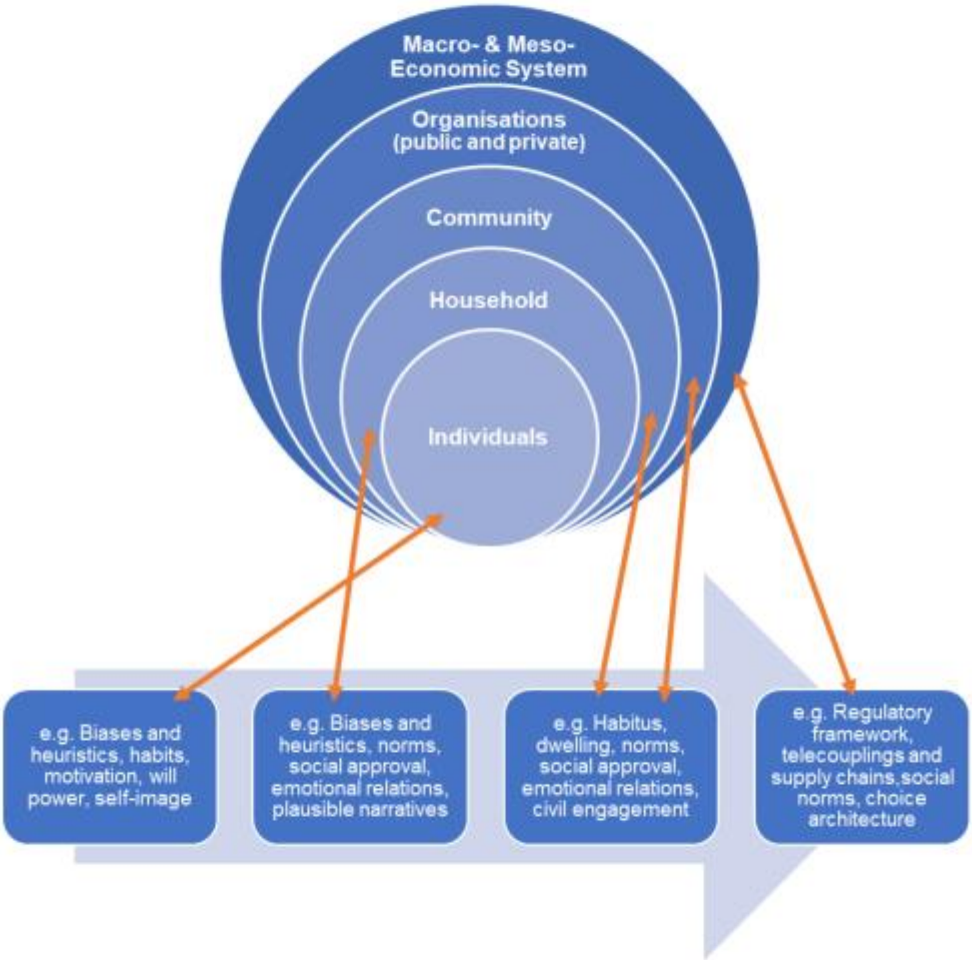

Figure 1: *Drivers influencing behaviour and where they originate*

Factors influencing individual behavior encompass prices, available options, and information; cognitive heuristics, biases, and habits; as well as community, regulatory, and socio-economic contexts. Decision-makers can modify the choice architecture in which individual behaviors occur to promote sustainable decisions. Recent studies have identified the most significant individual behavioral changes that can contribute to green growth. Choices affecting green growth include personal investment decisions (see Appendix – Case study: Sharing and rental opportunities for physical assets), modes of transportation (Case study: Switching from cars to walking and biking), adoption of low-carbon technologies (Case study: Fuel-efficient and clean stove uptake), farming practices, and compliance with environmental laws and regulations.

A recent study focusing on developed nations highlights behavioral changes that can lead to the largest reductions in individual greenhouse gas footprints, such as living without a car or avoiding transatlantic flights (Figure 2).

Organizations influence individual green growth behaviors in at least three key ways. First, they shape the work environments in which individuals make decisions and earn their incomes.

Second, they produce, offer, and regulate the product options available for individual consumption. Third, they generate many of the externalities that affect individuals and the ecosystems surrounding them. Although this topic is outside the scope of this paper, further research is necessary to explore organizational behaviors and their implications for individuals.

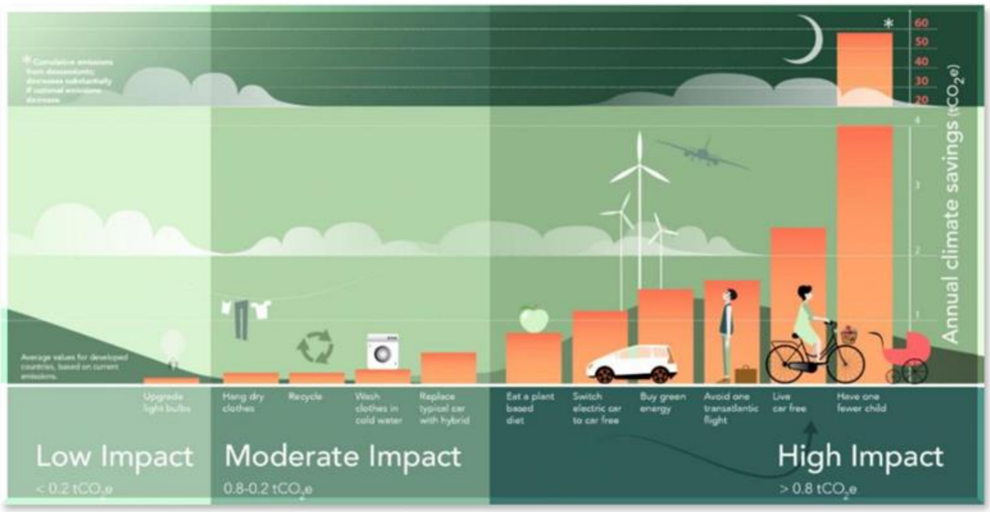

Figure 2: *Key individual behaviour choices ranked by impact on climate change*

Mainstream economics, in contrast to behavioral economics, primarily adheres to the rational choice theory of human behavior, viewing environmental challenges as market failures. This prevailing perspective assumes that market participants possess clear preferences, are informed about all relevant information, and make impartial decisions within their budget constraints. Based on this framework, mainstream economists advocate for market-based and regulatory solutions to address environmental market failures, such as Pigouvian taxes, contingent valuation, and tradable permits. They also employ Bayesian statistics and discounting to account for individual preferences.

Despite its limitations, traditional economics has provided two significant insights into individual behaviors related to green growth. First, it has highlighted that people make decisions by weighing various types of values, not solely price. These values are often difficult to compare. Classic economics identifies monetary benefits (like income and profit), monetary costs, opportunity costs, and non-monetary benefits (and costs). Non-monetary benefits often occur outside of markets and lack a standardized monetary value; for instance, the enjoyment of spending time with family or doing household chores. Traditional economics has explored various forms of non-monetary environmental values. This recognition of multiple forms of value helps to explain the phenomenon of choice overload, which can lead to suboptimal environmental decision-making.

Second, traditional economics has demonstrated that market failures—especially externalities and the tragedy of the commons—promote unsustainable behaviors among rational actors. Externalities incentivize price-sensitive individuals and groups, including businesses, to engage in unsustainable practices by evading the full costs of their economic decisions. The tragedy of the commons arises when resources are held in common without appropriate incentives for protection, leading to over-exploitation and degradation of those resources.

Behavioral insights provide new, cost-effective policy tools to facilitate green growth. While traditional economics continues to contribute to encouraging rational actors to adopt more sustainable behaviors, a closer examination of human behavior, including its deviations from rationality, reveals valuable insights for developing important new policy instruments.

Abstract

The development of the modern world is taking place against the background of the introduction of digital technologies, which is an objective and irreversible process that opens up opportunities for all spheres of society.
At the same time, digitalization is accompanied by negative consequences, generating many threats to the sustainability of economic systems.
The article considers the most significant problems of digital transformation and related economic risks. It is noted that, in general, digitalization provides society with many benefits and opportunities for intensification and efficiency of development, increasing the welfare of the population. But there are new risks that lead to structural changes in socio-economic and political-administrative systems that pose a threat to the economic security of the world's countries.
These risks include: technological disruption, cybersecurity and data vulnerability, digital skills deficit, labor migration, legal vulnerability, and economic inequality. Preventive measures to avoid negative development scenarios based on the use of modern technologies are proposed.

Keywords: disruption, market dynamics, innovation, cybersecurity, digitalization, economic risks

I. Introduction

The beginning of the 21st century is marked by the progressive movement of digital technologies, against the background of which economic and social systems, forms of international cooperation and business processes began to transform. This led to a reformatting of world economic and social relations, moving into the virtual space.

Digitalization continues to revolutionize the way businesses operate, business and interpersonal communication, and value creation. The new era of the digital economy has opened up unique opportunities for economic growth and increasing the efficiency of the global economy based on innovation and artificial intelligence. At the same time, digitalization, while creating broad opportunities and prospects, also has a negative effect since any development under conditions of uncertainty entails inevitable risks that are poorly studied and practically not calculated or assessed.

In the context of the dynamic digitalization of all life processes, society finds itself in a state of permanent risks, which aggravates the problems of making rational management decisions, both at the state level and at the level of economic entities (companies and citizens).

II. Methods

The concept of “Risk Society”, described in scientific works by Ulrich Beck (1984), takes the concept of risk beyond the scope of exclusively social problems [2]. Having described the universality and scale of risks, U. Beck came up with a definition of a “risk society”, which develops in conditions of uncertainty and unpredictability, and hypothetical losses are difficult to calculate and evaluate. Under these conditions, the implementation of current activities and decision-making, as defined by U. Beck, occurs reflexively and has a dual character. On the one hand, the increase of the role of public institutions in assessing the probability of developments and taking appropriate regulatory measures are aimed at minimizing risks. On the other hand, the changes introduced create new risks, expanding the range of uncertainty and unpredictability.

It is known that any decision made is associated with or entails certain risks, the fact of the occurrence of which can lead to identification of their form. The development of socio-economic systems is always accompanied by risks, which is the norm and at the same time a trigger for the rationalization of subsequent actions.

In 2017, The Global Risks Report [2] was presented in Davos (Switzerland), in which, on the basis of large-scale research work, 30 global risks of the most common nature were presented, and also 13 trends in the development of the world community for 10 years perspective in the context of the transition to a digital development model were described. Potential risks and threats were aggregated into five main groups: geopolitical, economic, technological, social and environmental.

In the annual report of the World Economic Forum 2024, these risks were confirmed, with clarification and emphasis on disinformation and polarization of society as the main modern threats [3].

The scientific research is based on a number of works of modern domestic and foreign authors, considering the issues of threats of economic nature in the period of digital transformation. This allowed, on the one hand, to generalize the accumulated experience of scientific thought, on the other hand, to identify and present new challenges arising in the conditions of digitalization in such a rapidly changing environment.

The purpose of the article is to identify the main economic risks of the digital format of society development, the factors that determine their impact on the socio-economic system.

The work used traditional methods of scientific cognition: generalizations and characteristics, observation and comparison, as well as information-analytical and statistical methods of research.

III. Results

Economic threats against the background of digital transformation create serious challenges to the stability of economic systems, their level of safety and security. This characterizes the main risk of an economy developing and operating on the basis of digital technologies. Digitalization leads to increased openness of national economic systems, making them more vulnerable to the negative impact of external factors. This problem is not only economic, but also political, ideological, social and other in nature, since information technologies reduce the security of the national system from negative external influences (the forms of manifestation are financial espionage, information and psychological pressure, manipulation with financial assets and instruments, and many others).

Also, the use of digital technologies increases access to companies' commercial and financial data, increasing the vulnerability of their financial stability and competitiveness. Thus, there is a scaling of criminal activity in the financial and economic sphere, against the background of which the threat of loss of control over the activities of companies increases, the likelihood of loss of

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

property arises, etc.

High risks also arise for each individual in the field of personal finance management, regarding the use of personal data for criminal purposes, the threat of losing jobs, and, consequently, a source of income.

Thus, the composition of probabilistic risks in the context of digitalization is quite extensive and affects all spheres of society: government, commercial and personal interests.

Currently, there is a growing debate in the scientific community regarding possible risks that have already become obvious and that are possible in the future. At the same time, the opinions of experts differ regarding the real threats and assessments of their impact on socio-economic processes.

One of the main economic risks associated with digital transformation is the disruption of traditional markets, business models and business processes. Indeed, the rapid implementation of new technologies, such as artificial intelligence (AI), blockchain and the Internet of things (IoT), have the potential to disrupt a number of economic sectors, the products and services of which, as well as their business processes and logistics systems, are beginning to become obsolete quite quickly , and competition intensifies. Against the background of dynamic technological development, the pace of which is accelerating, market volatility is increasing, to which companies cannot respond quickly and adequately, thereby losing profits and competitiveness

To avoid this, or mitigate the negative consequences, companies need to increase investment in research and development, promoting a transformative culture of innovation and flexible management decision-making methods to meet increasing market dynamics.

But not all companies can afford this, but only those ones that have accumulated stability in their segment for years, have a high or sufficient level of capitalization and reserve resources. Unfortunately, the changes taking place will lead to a selection of the business community, with the strongest companies remaining “afloat”.

The consequence of these processes in a negative context will be a sharp reduction in jobs, and, consequently, it will lead to a reduction in income due to stagnation of wages [2]. The problem of job loss is one of the most urgent and most widespread among those discussed and studied. In addition, the threat of job losses, caused by the processes of replacing human labor with information and digital technologies, is incomparable with any economic and financial crisis of past years in scale and consequences.

In the context of the introduction of digital technologies, the labor market is undergoing a structural transformation, when traditional employment is replaced by platform forms and methods of using labor resources, which has the potential for global qualitative changes, simultaneously associated with the risks of intensification of competition and increased restrictions for a significant part of those employed in the economy.

On the one hand, digital transformations, provided they are managed well, lead to increased diversification of employment and improved quality of life [1], on the other hand, they put forward new qualification requirements, increasing competition and competency gaps in the labor market. Platform employment is growing rapidly, but is not uniform across countries, leading to global inconsistency in its regulation. Currently, there are several approaches to regulating platform qualifications and employment. Some countries are taking a wait-and-see attitude regarding the introduction of regulations, while others are actively introducing legal initiatives to regulate platform employment.

By now, a unified approach to the regulation of the digital labor and employment market has not been developed; there is no scientific basis for the concept of its development, which stagnates the processes of its functioning both within national systems and on a global scale. The complexity of managing migration processes arises.

The migration policy of states in a traditional economy was focused mainly on regulating the movement of labor, which historically consisted of workers engaged in non-standard forms of labor and having predominantly temporary employment. However, in the context of digital transformations, new forms of labor, demonstrating high growth rates, lead to a change in the classical nature of the labor market, when standard (traditional) forms of employment, prevailing in the main market segments, are replaced by other forms of organization and implementation of labor activity (platform labor based on information-communication technologies). Traditional migration is being replaced by virtual and telemigration [5], a new digital labor market with a changing structure and qualitative content of the demand and supply of labor resources is being formed. Its main characteristics are the rapid flow of labor from one area to another, the rapid growth of new professions and specialties.

According to MasterCard forecasts, the global platform economy will double in size by 2023 compared to 2018 and by 2027, the volume is predicted to be $864.7 billion [8].

Thus, in the near future, platform employment will replace traditional forms of labor organization, which in many ways has positive effects such as expansion of jobs, employment flexibility, transformation of migration into the integration of highly qualified labor. At the same time, gaps between countries in the speed of entry into the digital world and the use of advanced technologies, including gaps in the development of the labor market, can lead to negative effects, which include instability or loss of income, insufficient qualifications to work in new conditions, and social isolation. Countries need consolidation in regulating migration and labor employment processes.

Cyber security and data vulnerability are another one of the most common problems among researchers, which has now received more evidence of its reality and danger. Digitalization has the property of total and rapid spread, the tools of which are available to the criminal world, sometimes to a greater extent than to institutions regulating life processes. The risk of cyber attacks and identity theft has already become an obvious reality: infection with malicious software; fraudulent attacks and extortion leading to financial losses, causing damage to the population and companies (loss of trust and reputation among consumers); loss of confidentiality and protection of personal and corporate data.

Prevention of these actions also requires significant financial investments in their own security through the implementation of reliable cyber security measures (encryption, multi-factor authentication and regular security audits) on the part of companies and ensuring cyber security for all market participants on the part of the state.

The use of digital technologies to ensure cyber security in all areas not only requires high financial investments, but also significantly complicates the processes of interaction both within companies and in society as a whole.

On the one hand, companies that implement authentication systems in order to protect the personal data of their clients (for example, banks) greatly complicate the processes of interaction between employees and clients, when in order to make a decision on the requested service they have to overcome a multi-stage system of verification, approvals, confirmations, etc. On the other hand, the state also has to use the same complex algorithm of actions in all executive institutions, and in cases of failures, be the guarantor of the preservation of the rights and property of citizens. In addition, being the main guarantor of the rights and freedoms of its citizens, the state is obliged to significantly expand its participation in the creation of training platforms for the population, business entities of various forms of ownership, scale and type of activity and in this direction to closely interact with business, research centers and individuals to create a cyber security-oriented culture under the new conditions.

The peculiarity of digitalization, which distinguishes it from all previously historically important processes, is the speed of its spread and penetration, which greatly complicates the development of regulatory measures for the effective management of digital activities. As a result, organizations and citizens often face uncertainty regarding compliance with existing regulations and are unable to anticipate future changes in the regulatory environment. Failure to comply with regulatory requirements can result in unexpected legal and fiscal liabilities, fines and damage to reputation.

To mitigate this risk, it is necessary to monitor changes in legislation by creating and using appropriate software (information and consulting), companies need to conduct a thorough legal audit in real time, and the population needs to improve legal literacy, or seek help from specialists. Yet again, this is costly, more labor-consuming in terms of the intensity of actions and attention on the part of all users.

Of course, digital transformation, which has become a reality and inevitability, requires certain skills for all members of society. In the public and corporate sectors of the economy, there will be a growing demand for qualified personnel capable of using advanced technologies to make management decisions, stimulate innovation and increase productivity. However, many government agencies and private companies have difficulty finding staff to meet current demands, leading to a widening digital skills gap. In addition, automation and artificial intelligence may displace traditional jobs, causing unemployment and income inequality (this problem was outlined above). To solve this problem, organizations of all ownership types must invest in digital skills development, reskilling and upskilling to ensure their workforce has the capabilities to thrive in the digital economy.

For citizens, the presence of digital skills becomes a determining condition for strengthening their personal potential and the ability not only to use it as a means of managing personal income, but also as a means of personal identification in the digital space (the use of digital platforms and tools for life support). At the same time, digital qualifications require constant learning, since they are being transformed too rapidly, new digital products and services are appearing, and new digital conditions are being created to ensure economic and everyday issues.

The problem described is of a more pronounced social nature but its economic component consists in danger of losing its usual way of life due to the loss of income received under the traditional economic model.

To solve this problem, all organizations (in the state and private sectors) must increase investment in digital skills, reskilling and upskilling to ensure that their employees have the opportunities to thrive in the digital economy, and the government should do the same for the unemployed population. Besides, encouraging a culture of lifelong learning and career development can help employees adapt to changing work roles and new technology trends.

IV. Discussions and conclusions

Digital transformation poses a real threat of deepening socio-economic inequality and growth of the digital divide. Digital access, internet use and digital skills are not evenly distributed across the population, leading to differences in economic opportunities and access to vital services. In this regard, for all countries around the world, bridging the digital divide and ensuring equal access to digital technologies is critical to stimulate economic growth and reduce inequality.

Investing in digital infrastructure will become a universal and very large-scale task, the solution of which can only be achieved through joint efforts on the part of national systems, businesses and citizens; international institutions are also needed to regulate these processes.

A strategy for reducing inequality as a result of digital influence should be developed at the level of interstate interaction and implemented through the expansion of digital infrastructure, open access to broadband Internet and advanced software, supported by large-scale training and retraining programs for citizens of all social categories. But its implementation depends on coherency between the world's leading countries regarding to the negative effects of the digital world.

The problems described above are far from being solved; their number, degree of negative impact and possible destructive consequences are wider and more diverse in many ways. We have described some of them that, in our opinion, are the most acute and have already become a reality in a changing world.

Among them:

1. Technological disruption and market dynamics.
2. Cyber security threat and data vulnerability.

3. Complications of compliance with regulatory standards and other legal challenges.
4. Deficit of digital skills among economic entities and the population, movement of labor.
5. Economic inequality and digital gap

To summarize all of the above, we`d like to note that the identified economic risks and threats of digital transformation have one common property – you can only resist them if all economic entities work on a large-scale and permanent basis to adapt to the changes that are taking place. This work requires significant financial costs, personal, corporate and organizational efforts, readiness to accept reality, self-development and self-learning.

In conclusion, we note that digital transformation has many advantages and opens up wide opportunities for personal growth and self-development, expands the range of innovations and investments, creating new products and services. At the same time, it poses significant threats to national economic security, giving rise to new risks that have no analogues in scale and consequences. Moreover, negative consequences are difficult to assess and calculate, which makes it difficult to take preventive measures to fight them, both at the government level and in the corporate and private sectors.

Understanding of current changes, the ability to accept and adapt to them will greatly contribute to the right attitude towards proactive action in all areas.

Acceptance of digital transformation and understanding its benefits, will allow using them for driving sustainable economic growth and creating value for stakeholders. This requires new mechanisms for proactive risk management, investment in cyber security, and the development and strengthening of digital skills by all members of society. Coordination of actions within national systems and at the interstate level will make it possible to mitigate the entry into new conditions without significant losses. Countries need to consolidate joint actions in the areas of scientific research, legal initiatives and advanced technological achievements, despite existing geopolitical differences and contradictions.

Abstract

This paper explores various economic models and strategies that have successfully facilitated transitions toward sustainable development in different regions around the world. By analyzing the mechanisms employed in these transitions, the study identifies key economic, policy, and institutional factors that contributed to success. The analysis spans different sectors, including energy, agriculture, and manufacturing, with a focus on green technologies, circular economy practices, and renewable energy integration. The paper also reviews international cooperation efforts, regulatory frameworks, and the role of innovation in driving sustainable growth. The findings suggest that a combination of public policy incentives, private sector engagement, and social inclusivity is crucial for achieving long-term sustainability. Case studies of countries such as Sweden, Germany, Costa Rica, and China illustrate the diversity of approaches and the lessons that can be drawn from them. The research contributes to a better understanding of the pathways and tools necessary for a global transition toward a sustainable economic model.

Keywords: green economy, circular economy, renewable energy, policy incentives, innovation, international cooperation, environmental sustainability, transition strategies

I. Introduction

In recent decades, the global community has increasingly acknowledged the necessity of sustainable development as a fundamental principle for economic growth. Sustainable development involves pursuing economic progress while addressing environmental protection and social equity, ensuring the well-being of both current and future generations. As societies face the impacts of climate change, resource depletion, and social inequality, understanding the economics of sustainable development has become critical. This research paper explores the complex interaction between economic principles and sustainable development goals, highlighting the challenges impeding progress and examining potential solutions. By synthesizing existing literature and empirical evidence, the paper aims to illuminate the intricacies of achieving sustainable development from an economic standpoint. The urgency of addressing sustainability issues is evident in the rising frequency of environmental disasters, increasing income inequality, and ecosystem degradation. In this context, policymakers, businesses, and civil society are being urged to adopt comprehensive approaches that balance economic growth with environmental care and social inclusivity. Through a multidisciplinary perspective, this paper seeks to dissect the economics of sustainable development, shedding light on the trade-offs, synergies, and policy measures required to build a more equitable and resilient future. By critically examining existing frameworks, identifying knowledge gaps, and proposing innovative strategies, this paper aims to contribute to the ongoing dialogue on sustainable development and stimulate action toward a more sustainable and prosperous world. Sustainable development has become a critical concern in today's world, as societies face the pressing challenge of balancing economic growth with environmental protection and social equity. Popularized by the Brundtland Commission in 1987, sustainable development is defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." Since then, it has served as a guiding framework for governments, businesses, and communities worldwide. The pursuit of sustainable development is complex, involving the interconnectedness of economic, environmental, and social factors. Economists play a key role in addressing these challenges by analyzing trade-offs, creating incentives, and developing policy frameworks to support sustainable practices. The economics of sustainable development covers a broad spectrum of topics, including resource management, the transition to clean energy, poverty reduction, and climate adaptation. Despite widespread acknowledgment of the need for sustainability, significant challenges remain. Economic systems often prioritize immediate profits over long-term sustainability, leading to resource depletion, worsening inequality, and environmental degradation. Furthermore, many sustainability issues are global in scope, requiring international collaboration, which is often hindered by political and economic conflicts. In this context, the demand for innovative solutions is more urgent than ever. This review paper aims to provide an in-depth exploration of the economics of sustainable development, focusing on the obstacles to achieving sustainability and the possible ways forward. By integrating existing research and identifying areas where further study is needed, the paper seeks to enhance understanding of the economic forces at play in sustainable development and to guide the creation of policies that foster a more inclusive, resilient, and environmentally conscious global economy.

II. Methods

This paper employs a qualitative research design to investigate the economics of sustainable development, focusing on identifying challenges and exploring potential solutions. Qualitative methods are particularly well-suited for an in-depth analysis of the complex interactions between economic factors and sustainable development objectives, allowing for a nuanced understanding of the topic.

Data will be collected through an extensive literature review, drawing from academic journals, books, reports, and other scholarly materials that address the economics of sustainable development. The review will utilize online databases such as Google Scholar, JSTOR, and PubMed to access relevant research. Additionally, reports from governmental and non-governmental organizations, as well as industry white papers, will be included to provide a broad perspective on the subject.

The inclusion criteria for the literature review will focus on sources that discuss key aspects of sustainable development economics, such as economic growth, environmental sustainability, social equity, poverty reduction, and technological innovation. Only peer-reviewed articles and reputable sources published within the last ten years will be considered to ensure that the research is both up-to-date and credible. Exclusion criteria will include studies that do not directly address the economics of sustainable development or lack empirical evidence to support their findings. Non-English language publications will be excluded due to language constraints.

Ethical considerations in this research involve proper citation and acknowledgment of all sources to avoid plagiarism. The accuracy and relevance of the information will be critically assessed, with attention given to respecting diverse viewpoints in the literature. Care will be taken to avoid bias in both the selection and interpretation of data, ensuring an objective and balanced analysis of the economics of sustainable development.

III. Results

A series of recent crises and growing instability in the global economy and politics, as well as an increasing number of global risks and challenges, force us to reconsider the concept of sustainable development. Previously perceived as an abstract theoretical construct, the system of global goals and objectives that seemed distant from everyday problems has been seriously tested for viability and relevance in recent years. For everyone who has lived through the COVID-19 pandemic with its profound socio-economic consequences, and who is now observing fundamental changes in the economy and geopolitics, the term "sustainable development" takes on new meaning and significance.

Attempts to question the need to follow the UN Agenda for Sustainable Development until 2030, adopted in 2015, against the backdrop of intensifying crises have quickly given way to an awareness of the importance of joining forces to achieve the 17 Sustainable Development Goals (SDGs). This requires efforts at all levels - from states and regional associations to municipalities, companies and individuals representing society as a whole.

Increased attention to the topic of sustainable development is also due to worsening climate problems. Experts once again emphasize the imbalance in the climate system and the onset of irreversible consequences for the climate. Global environmental and climate risks have been leading the annual World Economic Forum (WEF) global risk reports for several years in a row, which only confirms the need for urgent action.

IV. Discussion

The concept of sustainable development is a process of economic and social transformation, in which the use of natural resources, investment direction, scientific and technological progress, personal development and institutional changes are coordinated in such a way as to strengthen the current and future potential to meet human needs and aspirations. At the corporate level, this concept covers a system of principles, processes and results aimed at maintaining a balance between economic, environmental and social aspects both in companies and in society as a whole. Maintaining this balance contributes to the preservation of vital systems and long-term well-being. The concept is closely related to the ESG approach (environmental, social, governance - the environment, society and corporate governance), which is aimed at managing non-financial risks taking into account the impact on the environment, society and the principles of effective management. This approach includes such processes as ESG rating, ESG investing and ESG transformation, and represents a continuous improvement of business processes. Current economic and political crises have only increased the importance of strengthening the sustainability of companies and made it urgent to develop more relevant ESG criteria for long-term development.

In the post-pandemic era, not only institutional investors, but also politicians in developed countries are declaring their commitment to ESG principles, paying attention to the implementation of "green" technologies, human-oriented corporate practices and improving the quality of life. The concept of the "green" economy, which emerged at the end of the 20th century, remains important, focusing on the need to minimize the negative impact of economic activity on the environment, placing sustainable development and environmental safety above simple economic growth at any cost.

The process of aligning the Decision Support System (DSS) to sectoral modeling varies based on the capabilities and flexibility of the selected modeling methodology. This section, along with the following one, details how this alignment is conducted for the Global Energy Model (GEM).

The integration of thematic results into GEM, as well as the alignment of outcomes, is influenced by the degree to which each sector experiences endogenous feedback loops.

Soft Coupling of Methods

The soft coupling of methods can be achieved either through direct input or calibration:

- Direct Input: This involves importing the results from thematic modeling as data time series into GEM. When there is limited or no relevant structure in GEM or when the parameters are not influenced by endogenous feedbacks, the outputs from sectoral models are fed into time-based table functions within GEM.
- Calibration: This approach is utilized to align GEM results with sectoral modeling outputs when the relevant indicators are influenced by GEM's endogenous feedback structure. Calibration requires several steps, which will be demonstrated using the example of total energy demand.

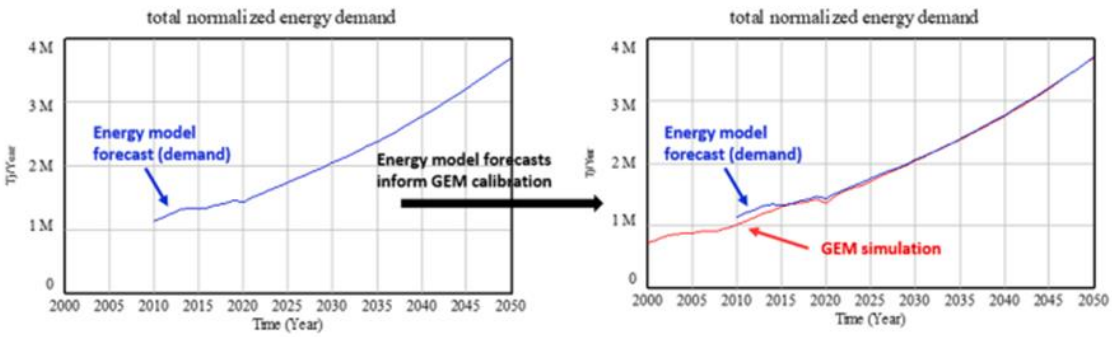

Figure 1: *Illustration of reference mode and the alignment of behavior in GEM*

Steps for Calibration

1. Creating an Artificial Simulation:

- The first step involves generating a simulation specifically for calibration purposes. In this case, the energy demand data for alignment is sourced from the Low Emissions Analysis Platform (LEAP) (SEI, 2018).
- The System Dynamics (SD) modeling software enables the importation of data from sectoral models into GEM and the creation of a simulation file that can be visualized. This imported data is termed "reference modes" and is utilized to conduct behavioral validation tests.
- The left graphs in Figure 3 illustrate the reference data from the LEAP model, specifically total energy demand and energy-related CO2e emissions, which are essential for calibrating these parameters within GEM.

2. Importing Baseline Real GDP Data:

Since LEAP does not account for feedback mechanisms affecting macroeconomic productivity, baseline real GDP data is imported as time series. This is necessary because GEM incorporates feedback loops that treat real GDP as a driver of energy demand and related costs. These factors subsequently impact sectoral real GDP through total factor productivity.

The interplay between real GDP and energy demand is reciprocal; thus, a change in real GDP influences energy demand and vice versa. To facilitate calibration of GEM in line with LEAP projections, it is crucial that real GDP remains exogenous during the calibration process to replicate the conditions (ceteris paribus) present in the LEAP model.

This calibration process ensures that the energy demand and CO2e emissions in GEM are accurately aligned with the projections and feedback mechanisms represented in the LEAP model, thereby enhancing the reliability of the model's outputs.

The events of 2022–2023 are increasingly raising doubts about the comprehensive achievement of the Sustainable Development Goals (SDGs) within the framework of Eurasian integration. The destruction of supply chains, rising prices for raw materials and commodities, including food, are creating difficult conditions for achieving the SDGs, especially those related to ending hunger (SDG 2) and ensuring health and well-being (SDG 3). Sergey Glazyev, Minister for Integration and Macroeconomics of the EEC, notes the trend towards chaos in food markets, emphasizing that global resources and technologies make it possible to produce food for 20 billion people — twice as many as the current population of the planet. However, the problem lies in the unfair distribution of resources, unequal international economic relations, and rising prices caused by the quantitative easing policy of reserve currency issuers.

For an effective transition to sustainable development, it is necessary to develop an adequate system of goals and indicators. It is necessary to improve the methodology for selecting statistical indicators reflecting the achievement of SDGs in the EAEU countries, as well as to create new indicators for missing areas. It is also important to implement international standards and take into account recommendations, such as the OECD recommendations, to improve the quality and comparability of economic statistics. This is critical for the formation of the EEC's own dossier on sustainable development and the preparation of a new report. Of particular importance is the coordination of statistical activities in the EAEU region, strengthening professional and research potential, as well as the introduction of advanced international standards in methodology and data classification.

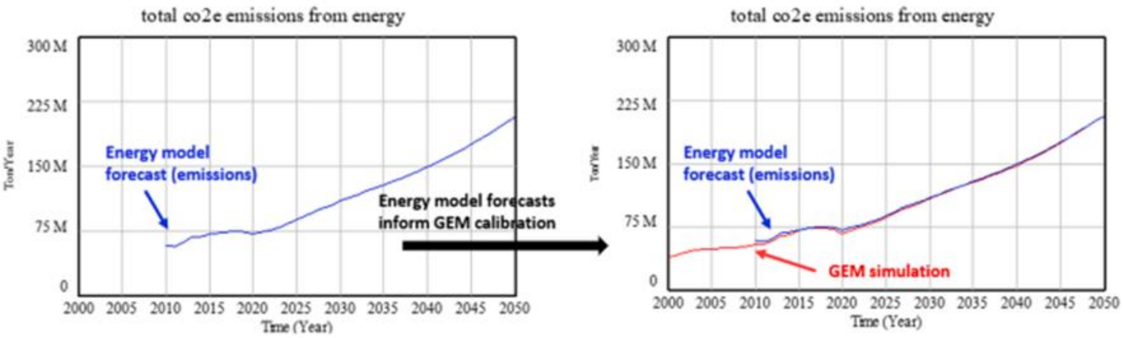

Figure 2: *Illustration of reference mode and the alignment of behavior in GEM*

The demand aligns with the results from LEAP, and closing the endogenous feedback loops enables us to (i) examine how macroeconomic indicators evolve under LEAP projections and (ii) subsequently adjust the energy demand trajectory forecasted by LEAP. Figure 4 illustrates a comparison of simulations with and without the endogenous feedback effects through total real GDP. The findings indicate that the energy mix derived from the sectoral model contributes to increased economic growth (for instance, through lower costs). This additional growth results in greater energy demand and related emissions than what LEAP initially predicted.

This process is conducive to iterations. Specifically, the updated total real GDP forecast from GEM can be integrated back into LEAP. This integration aids in assessing whether the anticipated emission reductions remain achievable or if the increased demand necessitates more robust mitigation efforts. This methodology is applied across all modules except for ecosystem service provisioning. The exception arises because modeling current and future ecosystem service provisioning requires iterative processes among GEM, GIS, and ecosystem services models like InVEST.

annabreusova@yandex.ru

Abstract

In the context of global climate change and increasing environmental challenges, the concept of a green economy has emerged as a crucial framework for achieving sustainable development. This paper examines the transformation of traditional business models within the framework of a green economy, emphasizing the imperative to integrate environmental and social considerations into strategic planning. By analyzing the key principles of a green economy—such as carbon emission reduction, resource efficiency, sustainable production and consumption, and biodiversity support—this study explores how these principles influence the adaptation of business practices. The paper further investigates the role of innovation in facilitating this transformation, highlighting how new technologies and business practices can lead to reduced environmental impact while also enhancing economic performance. Through case studies of successful transitions to sustainable business models, the research illustrates the diverse approaches organizations can take to align their operations with green economy principles. Moreover, the paper addresses the challenges enterprises face in implementing eco-friendly technologies, including regulatory barriers, financial constraints, and the need for a cultural shift within organizations. It argues that overcoming these challenges is essential for the successful transition to a green economy, which not only promotes ecological sustainability but also creates new opportunities for growth, resilience, and competitive advantage.

The findings underscore the importance of collaboration among stakeholders, including governments, businesses, and communities, to create an enabling environment for sustainable practices. Ultimately, this research contributes to the understanding of how a green economy can serve as a new paradigm for traditional business models, fostering a harmonious relationship between economic development and environmental stewardship.

Keywords: green economy, sustainable development, traditional business models, ecological sustainability, innovation, resource efficiency, biodiversity, climate change, eco-friendly technologies, strategic planning

I. Introduction

The United Nations Conference on Sustainable Development, commonly referred to as Rio+20, was initiated amidst significant concerns regarding the global economic landscape. Within this context, "green economy" was selected as one of the two primary themes of the conference, drawing from an expanding body of literature focused on green economy and growth. This research investigates the interplay and impact of the dual crises on the emergence of "greening" as a potential solution. The objective is to analyze what defines and differentiates the proposals found in twenty-four sources on the green economy, which include policy documents from international organizations and think tanks, as well as academic research papers. It also aims to explore the implications and meanings of the burgeoning greening agenda for sustainable development as we progress into the 21st century.

Using a systematic qualitative analysis of textual materials, the study identifies three categories of discourse that shed light on the meanings and implications of greening: "almost business as usual," "greening," and "all change." By examining these categories in relation to Dryzek's classification of environmental discourse, the research reveals three interconnected patterns: (1) scarcity and limits, (2) means and ends, and (3) reductionism and unity. These patterns enhance our comprehension of the tensions that arise among emerging propositions related to greening.

Furthermore, the patterns elucidate the significance and implications of greening for sustainable development, highlighting a trend toward the economization and polarization of discourses. The analysis also points to an enduring weak interpretation of sustainable development and a conflict between the stabilization or transformation of the dominant socioeconomic paradigms that shape its conceptualization.

As the world grapples with the escalating impacts of climate change, environmental degradation, and resource depletion, the traditional paradigms of economic growth are being increasingly scrutinized. The need for a transformative approach to development has given rise to the concept of a green economy, which seeks to promote economic growth while simultaneously addressing environmental and social challenges. Defined broadly, a green economy is one that is low in carbon emissions, resource-efficient, and socially inclusive. It emphasizes sustainable practices that support human well-being while protecting the planet’s ecosystems.

The traditional business models that have dominated economic systems for decades often prioritize short-term profits over long-term sustainability, leading to significant negative externalities, such as pollution, loss of biodiversity, and climate-related disasters. These practices not only threaten the health of the environment but also jeopardize the very foundations of human society by undermining the resources upon which livelihoods depend. In contrast, the principles of a green economy advocate for a systemic shift toward sustainability, encouraging businesses to rethink their operational frameworks and strategies.

This paper seeks to explore the transformation of traditional business models in light of the green economy paradigm. It will examine how organizations can adapt their practices to align with sustainability goals, highlighting the essential role of innovation and strategic planning in this transition. By integrating environmental and social considerations into their business operations, companies can not only mitigate their impact on the planet but also unlock new avenues for growth, resilience, and competitive advantage.

Furthermore, this introduction sets the stage for a detailed analysis of the key principles underlying the green economy, the challenges organizations face in adopting these principles, and the potential benefits of embracing a more sustainable approach to business. Ultimately, the paper aims to illustrate that the shift towards a green economy is not merely a trend but a necessary evolution that can redefine the relationship between economic development and environmental stewardship, ensuring a viable future for generations to come.

II. Methods

This study employs a multi-faceted research approach to analyze the transformation of traditional business models within the context of the green economy. The methodology comprises several key components designed to gather comprehensive data and insights into the subject matter:

1. **Literature Review**: A thorough review of existing literature on green economy principles, sustainable development, and traditional business models was conducted. This review

includes academic articles, books, reports from international organizations, and case studies that provide foundational knowledge and context for understanding the intersections between economic practices and environmental sustainability. The literature review serves to identify key themes, challenges, and opportunities that characterize the transition to a green economy.

2. **Case Studies**: Selected case studies of organizations that have successfully transformed their business models in alignment with green economy principles were analyzed. These case studies were chosen based on their relevance to various industries and their demonstrated commitment to sustainability. The analysis focuses on the strategies employed, the challenges encountered, and the outcomes achieved, providing real-world examples of how businesses can implement sustainable practices.
3. **Interviews and Surveys**: Semi-structured interviews and surveys were conducted with key stakeholders, including business leaders, sustainability experts, and policymakers. These discussions aimed to gather qualitative data on the motivations, barriers, and best practices associated with transitioning to a green economy. The insights gained from these interviews and surveys offer a deeper understanding of the subjective experiences and perspectives of those directly involved in the transformation process.
4. **Comparative Analysis**: A comparative analysis of different business models was performed to identify the factors that contribute to successful implementation of green economy principles. This analysis involved examining the differences and similarities in approaches taken by businesses across various sectors, such as manufacturing, agriculture, and services. By comparing these models, the study aims to highlight the adaptability of green economy principles and their applicability in diverse contexts.

III. Results

In light of the uncertain recovery of the global economy, governments from both mature and emerging economies, various international organizations including the UN, and stakeholders from civil society and academia have all played a role in advocating for a green economy or green growth as a means to address the ongoing crises. These terms are frequently used interchangeably, encompassing a spectrum of ideas related to low-carbon development. This range spans from the specific focus on eco-industry and environmentally friendly production to a comprehensive redefinition of an entire country's or region's economy. Between these two extremes lie policies aimed at promoting low-carbon economies or enhancing efficiency and productivity, which often overlap.

These approaches emphasize varying degrees of concepts such as dematerialization, decoupling resource use, valuing ecosystem services, and improving energy efficiency, all propelled by technological innovation. The notion that undervaluing natural capital impacts not only economic efficiency but also both growth and the quality of that growth concerning human welfare has gained recognition from international and national organizations since the influential Millennium Ecosystem Assessment was published. Additionally, scholars connect green growth and green economies to positive shifts in the eco-industry sector, which is transitioning from downstream environmental protection technologies to resource-saving technologies driven by innovation and competitive markets. They also highlight a growing interest in re-evaluating lifestyles beyond the traditional sustainable consumption agendas and the need to transcend the classic divide between individualistic and systemic methodologies, as well as the role of technological and cultural factors.

Consequently, a substantial portion of the policy and academic literature on greening growth and economies merges environmental and sustainability discourses with industrial and economic policy discussions, aiming for win-win solutions and positive cycles of progress and prosperity.

Among international organizations, the United Nations Environment Programme has taken a leading role in shaping and promoting the green economy as a driving force for growth, job creation, and poverty alleviation. It defines a green economy as one that enhances human well-being and social equity while significantly reducing environmental risks and ecological scarcities.

Against this backdrop of multiple crises and the emergence of new ideas for economic growth, 191 UN member states convened in Rio de Janeiro from June 20 to 22, 2012, for the UN Conference on Sustainable Development, known as Rio+20. This event marked the twentieth anniversary of the UN Conference on Environment and Development, which elevated sustainable development to an internationally recognized concept and normative goal, as well as the fortieth anniversary of the UN

IV. Discussion

The theme of a "green economy in the context of sustainable development and poverty eradication" was introduced as one of the emerging challenges during the UNCSD's first preparatory committee meeting in May 2010. Several intersessional and preparatory meetings at the UN headquarters in New York, along with country-led initiatives and reports, contributed to the development of the "zero-draft" outcome document in December 2011. Tariq Banuri, who was the Director of the Division for Sustainable Development at the UN during the lead-up to Rio+20, provided insight into the reasoning for focusing on the green economy in an interview. When asked if the green economy might "minimize" sustainable development, Banuri clarified that the green economy was firmly positioned within the context of sustainable development, aiming to align economic policies with social and environmental needs. He emphasized that focusing on the economy is essential, as it is an area requiring action.

In response to concerns about differing agendas between developed and developing nations and the fear that greening might hinder growth, Banuri acknowledged the crisis-driven nature of the agenda, explaining that the consensus was not about obstructing development but ensuring its possibility during times of crisis. This view was shared by both developing and developed countries. Banuri further addressed the idea that achieving sustainable development would require an economic paradigm shift, confirming the presence of an emergency mindset. He stressed that the goal was to find practical solutions rather than seeking a completely new paradigm.

A summary of national reports for Rio+20 highlighted concerns about the lack of clarity surrounding the green economy and the perceived risks, such as imposing conditions on aid and creating trade barriers. A detailed account of the process leading up to Rio+20 in the Earth Negotiations Bulletin underscored the controversy surrounding the UNCSD's decision. The green economy, though championed by UNEP as a key theme, encountered strong resistance from the G-77/China, resulting in a highly defensive and qualified text in this section of the document.

To discuss the idea of the green economy, its relationship to sustainable development, and the significance of its adoption within the Rio+20 agenda, it is essential to view it in a broader historical and economic context, especially considering the ongoing multiple crises. An initial qualitative analysis of the content from the 24 sources, along with reports on stimulus packages quickly passed by governments across the Atlantic, indicates that responses to these crises can be grouped into three main categories: (1) national stimulus packages, representing "almost business as usual" (BAU); (2) proposals to green the economy, labeled as "greening"; and (3) calls for socioeconomic transformation, described as "all change." Each category is characterized by its primary objective, its socioeconomic paradigm, and its vision of progress.

The "almost BAU" category refers to the stimulus packages, recovery programs, and bailouts implemented by major economies to mitigate the effects of the near-global financial collapse.

These measures often included "green stimulus measures," with large economies focusing on environmental initiatives within the broader context of their recovery efforts. Countries such as China, South Korea, the United States, Japan, and the European Union led the way in green investment packages, allocating significant funds to energy efficiency, infrastructure upgrades, clean technology markets, and research and development. The core of these responses was to reactivate the global market economy while addressing unemployment issues.

The greening efforts viewed the economic crisis as an opportunity for investment in the ecoindustry. Governments committed substantial funds to green projects, with a reported $512 billion being allocated globally, 22% of which was to be spent in 2009 alone. While these green stimulus packages were part of broader recovery strategies, they also demonstrated a shift towards greener policies. The overarching economic paradigm in this category remained tied to growth, framed within neoclassical economics, and reinforced by Keynesian approaches that emphasized state intervention in the economy.

The vision of progress within the "almost BAU" category was rooted in economic growth, with the assumption that growth would eventually benefit society as a whole. This incremental shift represented a move away from market fundamentalism toward a more active role for the state in shaping economic recovery and addressing both social and environmental needs.

The "greening" category refers to national and international efforts aimed at comprehensive strategies for greening economies. This approach is best exemplified by documents like the OECD's *Green Growth: Overcoming the Crisis and Beyond* (2009) and UNEP's *Global Green New Deal* (2009). The primary objective is to achieve resource-efficient, low-carbon growth. The socioeconomic paradigm is rooted in a technoscientific framework, with progress defined as efficient growth that benefits society as a whole and reduces poverty. This includes various shades of green, reflecting a gradual shift away from mainstream economic models toward propositions inspired by thinkers like Karl Polanyi. This shift reasserts the connection between the economy and society, moving beyond the state's rediscovered role in economic intervention, and incorporates ecological economic theories, which emphasize environmental limits and the need for equity across generations.

As we move further along the spectrum, the "all-change" category represents more radical approaches proposed by NGOs, think tanks, and heterodox economists. This category lacks a cohesive set of policies, but key documents like *World in Transition* (WBGU, 2011), *The Great Transition* (NEF, 2009), and the *Degrowth Declaration* (2010) embody the core ideas. The primary goals here include prosperity beyond traditional economic growth, the creation of steady-state economies, and the fostering of societies that prioritize well-being and sustainability. The degrowth movement, part of this category, critiques the primacy of economic growth, even in its sustainable forms, and calls for a reorientation towards human well-being and happiness. These proposals reflect a transformative socioeconomic paradigm that draws from natural sciences, social sciences, and humanities, rather than the more economic-centric approaches of previous categories. They also highlight the paradoxes of growth and efficiency, such as Easterlin's and Jevons' paradoxes.

In exploring these categories through the lens of John Dryzek's classification of environmental discourses, we see how each category aligns with varying degrees of reformist and radical thinking. Dryzek identifies two dimensions of human-nature interaction: reformist-to-radical changes and prosaic-to-imaginative alternatives to dominant political-economic structures. The "almost business as usual" (BAU) category aligns with Dryzek's reformist-prosaic "problem-solving" discourse, representing conservative and gradual approaches to change. The "greening" category overlaps with Dryzek's "sustainability" discourse, blending prosaic and imaginative elements. Finally, the "all-change" category fits with Dryzek's "green radicalism," representing a more imaginative and radical departure from current economic and environmental norms.

These distinctions help clarify the diverse responses to the green economy debate, from incremental reforms to more transformative visions of a sustainable future. Rio+20 fits into this framework primarily within the "greening" category, reflecting a reformist and moderate approach to sustainable development that aligns with the weak conception of sustainability. Held during the height of the global financial crisis, the agenda was shaped by both economic instability and growing environmental concerns. However, the emphasis at Rio+20 on the green economy—framed as a pathway to both economic recovery and environmental sustainability—largely mirrors the discourse of *ecological modernisation*, which advocates for more efficient, low-carbon growth without fundamentally questioning the dominant socioeconomic paradigm. This perspective seeks to "fix" the existing system through technological innovations and market-driven solutions, rather than shift to more radical alternatives.

The implications of Rio+20 for sustainable development, 20 years after the first Rio Summit (UNCED, 1992), suggest a continuation of the weak paradigm. While Rio+20 embraced green economy strategies, these strategies remain focused on efficiency improvements, resource management, and ecological modernisation rather than addressing deeper systemic issues, such as unsustainable consumption patterns or the need for a more transformative socioeconomic shift.

This is consistent with the broader literature on sustainable development, which critiques the weak version for prioritising economic growth and technological solutions over more profound social or environmental changes. Rio+20’s proposals, despite the green rhetoric, fall short of the more radical–imaginative dimensions represented by the "all-change" group, which advocates for paradigm-shifting transformations that prioritize well-being, equity, and ecological sustainability over economic growth.

Thus, Rio+20’s approach remains within the "reformist–prosaic" category of John Dryzek’s environmental discourse classifications, focusing on incremental changes and technocentric solutions. Its agenda, while progressive in terms of advocating for a greener economy, reinforces existing structures rather than challenging the global economic system in a way that the more radical discourses in the "all-change" category would demand. This is reflected in the underlying tension between the need to address immediate economic concerns and the more pressing, long-term sustainability challenges that still remain largely unaddressed.

•

Azerbaijan Technical University

Abstract

The article systematically analyzes the transition to innovative metallurgical technologies in the context of the priority direction of decarbonization. It is determined that at present the main direction of decarbonization can be considered the rapid development of electrometallurgy. Within the framework of this direction, oxygen blowing of liquid metal, extra-furnace treatment, the use of powerful transformers, automatic melting control, processing with synthetic slags, melting in induction furnaces, preliminary heating of the charge, and the widespread use of injection metallurgical processes are recognized as innovative technologies.
Reducing energy consumption in the production of electric steel has been put forward as the main task of metallurgical technologies. Two main directions of decarbonization in the steelmaking complex have been identified: intensification of smelting based on increasing the capacity of the furnace transformer and the introduction of modern "oxygen" technologies and a modular system in smelting.

Keywords: innovative technologies, decarbonization, priority areas, electrometallurgy, extra-furnace processing, injection processes

I. Introduction

It is known that the production of ferrous metallurgy is an industry with a large harmful impact on the environment and large-scale carbon dioxide emissions. Global climate change requires increased innovation activity in the metallurgical industry. The transition to innovative technologies can be considered as a priority direction of the decarbonization process in metallurgy. The main vector of this direction is electrometallurgy or the production of electric steel.

Current trends show that more than 80 percent growth in the use of the electric method in general steel production in recent decades is due to the introduction of innovations. Therefore, researchers propose to evaluate the criterion for accelerating innovative technologies in steel production as a derivative function of innovation growth (million tons/year), (million tons/year2) [1].

Researchers and specialists constantly analyze the role of innovative technologies in increasing the competitiveness of metallurgical products. It has been shown that innovative metallurgical technologies will play a decisive role in improving the quality of metal products in the coming decades and will ensure the protection of the leading positions of countries in the world market [2]. For example, in [3] the issue of removing hydrogen from the surface of liquid metal using a circulating vacuum as an innovative metallurgical technology is considered. It is shown that the removal of hydrogen from the metal surface in a circulating vacuum chamber is a long process and occurs at a very slow rate.

Analytical calculations have shown that removing hydrogen from the surface of liquid metal in the chamber of a circulation vacuum cleaner is not enough to obtain a low residual amount of hydrogen in the metal, and for this it is necessary to carry out additional technological measures.

II. The role of innovative metallurgical technologies in decarbonization of the environment.

In [4], promising innovative directions for the development of steelmaking were studied. It was shown that the share of electric steel in global steel production is more than 30%, in the USA this figure is approaching 40%. The main reasons are indicated as process flexibility, less dependence on the composition of primary raw materials, the possibility of producing alloy steels of various compositions and purposes, the use of large amounts of scrap metal, the possibility of automating processes and environmental aspects, and the rapid growth of electric steel production.

Based on the analysis of the current situation in metallurgical production, it has been determined that modern electric arc furnaces (EAF) have essentially become a smelting unit, significantly freed from the "dirty" metallurgical processing of steel.

Therefore, the priority development of electric steelmaking can be considered as the main direction of technical progress in metallurgical production. It is noted that the total energy consumption of EAF steel production is 1.5-1.8 times less than that of oxygen converters.

The study [5] presented the inevitable direction of development of electric smelting in the metallurgy of Russia, especially in the Ural region. It was shown that the technical and economic indicators of electric arc steelmaking furnaces (electrode consumption, melting time, energy consumption, etc.) have significantly improved in recent decades.

Out-of-furnace steel treatment processes are indicated as a major contribution to the achievements of electrometallurgy. Thus, out-of-furnace treatment allowed not only to abandon long cycles of melt reduction and oxidation and, therefore, to increase furnace productivity, but also to save energy and materials. Mainly, this allowed to significantly improve the quality of steel, to obtain steel with fundamentally new properties.

Thus, the conducted research allows us to consider the following processes as innovative in electrometallurgy: 1. Oxygen blowing. 2. Out-of-furnace processing. 3. Water-cooled panels. 4. High-power transformers. 5. Extended-arc welding. 6. Automated monitoring and control. 7. Foam plastic processing. 8. Use of water-cooled arcs. 9. Use of a new type of burner. 10. Tapping metal from the furnace bottom. 11. Ladle furnace processing. 12. Tapping liquid metal without residues ("swamp" melting). 13. Primary heating of the plate. 14. Injection methods or rubbing and blowing with gases.

In the context of the listed innovative technologies, methods for increasing the productivity of modern electric arc steelmaking furnaces were studied in [6]. It was shown that electric arc furnaces currently play an important role in steel production as the main metallurgical unit. EAFs, out-of-furnace processing units and continuous casting machines together make it possible to obtain high-quality steels with significantly lower energy costs and minimal impact on the environment.

It is shown that reducing the metal overheating temperature in the furnace is an effective method for increasing the EAF productivity. The necessity of such measures as high-temperature heating of furnace masonry, preliminary heating of materials added during the melting process, and the widespread use of heat-protective materials in the masonry of furnaces and fireboxes as methods for ensuring this process is substantiated.

The use of efficient energy-saving technologies in the steelmaking complex is considered in [7]. The analysis of technical and economic indicators of an electric steelmaking plant is carried out using an electric arc furnace as an example. Reducing energy costs in the production of electric steel is put forward as the main task of metallurgical technologies in our country.

The following are recommended as the main operations when implementing efficient energy-saving technologies:

1. EAF should be considered only for slag melting and obtaining liquid metal. All cleaning operations should be carried out using extra-furnace methods.

2. Steel smelting should be carried out using the advantages of liquid or "swamp" technology.

3. Only single-pass electric welding technology should be used in EAF. This technology involves increasing the capacity of the furnace transformer to 95 MVA and introducing a "furnace-ladle" device.

4. Minimization of heat losses in the furnace and firebox, preliminary heating of scrap metal, regular feeding of loading baskets into the furnace should be ensured.

5. To intensify the melting process, a modular system should be used. Here we consider such tricks as using fuel-oxygen burners, switching to oxygen injection and carbon blowing, and operating the furnace on long arcs.

6. It is necessary to ensure that the oven is constantly operating in foamed bags. This technology allows you to screen the electric arc operating in long arcs, protect the masonry and water-cooled panels of the furnace. Due to the injection of carbon, the technological advantage creates conditions for foaming of the resin during the reaction with oxygen.

It should be noted that in recent years much attention has been paid to the use of injection technologies in metallurgical production. Thus, in [8] it is shown that injection technologies are currently considered as a promising direction, widely used in metallurgy. This technology is used for processing alloys with materials similar to powders and for reducing heat-technical units.

The above studies showed that most metallurgical processes occur predominantly at the phase separation boundary, and the rate of these processes is determined by the total area of the contact surface. Intensification of the mixing of metal, resin and gases accelerates the course of physicochemical reactions in metallurgical furnaces.

This technology opens up wide possibilities for dephosphorization, desulphurization, deoxidation and alloying of steel, acceleration of slag formation, and carbonization of metal. Higher efficiency of this method is noted when feeding powder materials into the alloy in a gas flow.

The paper [8] also describes the characteristics of injection equipment for the implementation of injection technologies. The main process parameters determining the efficiency of injection technology are considered. As a result of experimental, calculation-analytical and design work, the main parameters of the powder gas flow in the injection metallurgical system were the carrier gas velocity, the mass density of the gas-dust mixture, the critical speed of pneumatic transport, the type of chamber blower (aerator and pneumatic-mechanical). It was determined that as a result of the use of this technology, a significant increase in the durability of the circulation vacuum cleaner pipes is observed.

In [9] the issue of reducing energy costs in the process of steel smelting in a large-tonnage electric arc furnace is considered. It is shown that at present the concept of steel production development is based on innovative technologies of energy-resource-saving and environmentally friendly production of electric steel.

Thus, modern metallurgical technologies include: utilization of heat from furnace gases; use of high-power electric transformers and alternative energy sources in the furnace; application of "oxygen" technologies to intensify smelting; foaming of pulp and combustion of process gases; synchronization of electrical energy and chemical energy of exothermic reactions

Studying the best practices of ferrous metallurgy enterprises allows us to identify two main areas of modernization of the steelmaking complex:

1. Intensification of the smelting process and application of modern "oxygen" technologies based on increasing the nominal power of the furnace transformer.

2. Application of a modular system (DANARC, Italy, DANIELI) in smelting processes.

The DANARC modular system combines maximum utilization of thermal energy, formation of foamed pulp and decarbonization of the liquid bath in one unit. The DANARC modular system has the following advantages over traditional equipment:

- blown coal dust is completely burned in the oxygen cylinder;
- efficient transfer of thermal energy is ensured in the bath;
- stationary placement of the module in the furnace frame is possible;
- ease of operation and minimal maintenance requirements.

It has been determined that the following results can be expected from the use of the DANARC modular melting system: increase in unit productivity - 17.3%; decrease in specific electricity consumption - 7.3%; reduction in defrosting time - 16.1%; decrease in specific electrode consumption - 39.4%; decrease in specific natural gas consumption - 14.8%.

The ways of increasing the productivity of electric arc furnaces are studied in [10]. It is shown that in the last 15-20 years the tendency of continuous increase in production of electrical steel in the world is clearly evident, and at present it makes up 40% of the total volume of steel production. The share of electrical steel in the USA is 45%, in Italy 60%, in Spain 72%, in Azerbaijan 80%.

The advanced development of electric steel production is associated with the direct application of advanced technical and technological developments and allows for a significant improvement in the technical and economic indicators of electric smelting. Increasing the productivity of electric arc furnaces is considered a complex task for metallurgists and power engineers and involves reducing the three main periods of smelting: preparatory, power and technological.

It has been established that further increase in EAF productivity can be ensured by better preparation of slag material for melting (slag scattering density 1.4-1.8 t/m2) and preliminary slag heating (400-500°C). These measures allow saving electricity by 70-75 kW.s/t, reducing melting time by 10-12%.

It is shown that after melting the slag, it is necessary to create and maintain a foamy pulp by blowing coke and oxygen to reduce radiation to the walls and roof of the furnace, as well as to ensure a "closed" arc combustion mode.

Increase in EAF productivity can also be achieved by conducting the melting process cycle in a single-pass mode, reducing the reduction cycle and conducting a number of cleaning processes with extra-furnace treatment.

Therefore, an important direction for increasing EAF productivity is increasing the capacity of the furnace transformer to 800-900 kVA/t. At this time, it is considered appropriate to increase the secondary voltage to 900-960 V.

In [11] it is shown that at present both rolled products and continuously cast blanks are widely used in the production of metal products. It is shown that the use of continuously cast blanks is more economically convenient, since in this case there is no need for additional rolling operations. In addition, the use of continuously cast blanks allows for a significant reduction in scrap metal, an increase in the output of healthy products, an increase in the productivity of rolling units and an improvement in working conditions.

In our country, the development of efficient technologies for the production of pipes and sheets from continuous casting is a pressing task for metallurgical enterprises. At the same time, the use of continuous casting machines allows reducing the cost of pipes by 10% and increasing the productivity of the pipe rolling unit by 15%.

A review of literary sources on the topic under study was conducted and the features of the change in the shape of the metal during radial sliding spreading of the works of Chekmarev A.P., Vatkin Yu.L., Potapov Yu.N., Polukhin P.Yu., Smirnov V.S., Fomichev Yu.A., Teterin P.K., Sveikin V.V., Kolikov A.P., Nikulin A.N. were determined and the works of other well-known scientists were analyzed.

Particular attention is paid to the advantages of the radial-sliding spreading method over other deformation methods. The intensity of compaction of the structure over the entire cross-section of the blanks, the possibilities and advantages of various schemes of the stress-strain state of the blanks are noted.

The conducted theoretical and practical studies allowed us to come to the following main conclusions in the analyzed work. The features of profiling the rear end of the workpiece in the form of a truncated cone and changing the shape of the cone of the workpiece during rolling on three-roll compression and piercing machines, based on the joint implementation of rolling processes on a compression machine, were determined.

Based on the products obtained during production tests and modeling using the Deform-3D program, it was established that smaller values of compression depth are observed when compressing a truncated cone blank 70 mm long.

During the physical and mathematical modeling of the process of profiling the end of the workpiece, it was found that as the profiling speed increases, the metal delaminates on the surface. Rational calibration and deformation modes have been developed, ensuring compression-free molding at the rear end of a truncated cone of a 70 mm long workpiece.

The process of profiling the tip of a workpiece with a cooled outer layer was simulated. It was found that cooling the outer layer at the end of the workpiece before profiling allows for a significant reduction in the depth of compression. In this regard, a cooling unit should be provided for in the working design for the reconstruction of the input section of a three-roll press machine.

In [12] it is shown that the fuel and energy complex of our country places serious demands on the products of the pipe industry. However, despite numerous theoretical and technological works, the problem of increasing the efficiency of seamless pipe production remains relevant.

The capabilities of pipe factories do not allow producing oil-quality pipes with a guaranteed level of properties that meet the technical requirements of developed countries. 95% of seamless pipes abroad are produced by continuous casting.

During the research work, the basic requirements for metal quality were scientifically substantiated and the following technological processes for the production of high-quality continuous casting blanks were developed:

- technology for the production of highly reliable oil and gas pipeline pipes operating at pressures up to 50 MPa;
- technology for the production of highly corrosion-resistant oil and gas pipeline pipes operated at low temperatures down to minus 60°C;
- technology for smelting carbon and low-alloy steels, furnace and out-of-furnace processing, continuous casting of square and round section pipe blanks.

III. Application of injection technology in metallurgy for decarbonization

Recently, interest in injection technologies has increased significantly, which are considered one of the most common technologies and one of the promising areas in metallurgy. These technologies are used for processing alloys with powder materials, as well as for gunning heating equipment units.

Shotcreting is a method of applying concrete mixture to a surface layer by layer under compressed air pressure [13].

It is known that most metallurgical processes occur at the phase boundary. The speed of these processes is determined by the total area of the contact surface. Intensification of the mixing of metal, resin and gases significantly accelerates the course of physical and chemical reactions [13].

A greater effect is achieved by accelerating alloy flows and simultaneously increasing the specific surface area of the reacting phases. These processes occur when using injection technologies. The high efficiency of this method is demonstrated when injecting powder materials into a metal alloy from a gas-bearing flow.

This method is used for dephosphorization, desulfurization, deoxygenation, acceleration of rust formation during steel alloying, and also for metal carbonization. In addition, injection of refractory materials can be used for twisting the mesh surfaces of metallurgical units [14].

Successful application of injection technologies depends on the use of injection equipment that provides a greater number of processes. In the 70-80s of the last century, work on the use of rapid carbonization of metal was carried out at various metallurgical plants.

At that time, pneumatic blowers manufactured in these establishments were used. The necessary scientific, technical and design research, operations and calculations were not carried out during the creation of these objects. Mainly for this reason, this promising method of metal processing has not yet found wide application [15].

In addition, work on improving injection technologies, especially on the design of powder blowing devices, has been developed abroad for many years.

The work carried out has led to the successful development of innovative metallurgical technologies in Japan, Germany, Austria, America and other countries. This promising direction has made it possible to intensify metallurgical processes, improve the quality of metal, and increase the service life of smelting units in these countries.

In the mid-90s of the last century, German injection devices were first used at the Serp and Molot plant (Moscow) with the participation of the Metallurgical Institute of the Russian Academy of Sciences.

In 1999-2000, the Institute of Metallurgy of the Ural Branch of the Russian Academy of Sciences completed the international project "Application of Casting Technologies at Metallurgical Enterprises of the Urals". As a result of studying the experience of applying casting technologies at European metallurgical plants, as well as research on the application of various powder materials to the alloy, it was recommended to continue work on equipping metallurgical enterprises with injection devices [16].

In this regard, there was a need to create casting equipment that is no different from foreign analogues in terms of quality, reliability and durability, but also meets the operating conditions of metallurgical enterprises in our country, and at the same time is significantly cheaper than imported ones [16].

For example, in the Russian Federation, experimental, computational-analytical and design work was carried out on the aerodynamics of powder-gas flows in injection-metallurgical systems and the influence of operating and design factors on the intensity of the output of sprayed materials from a pneumatic-mechanical feeder [17].

As a result of the conducted scientific research and experimental design work, the main parameters of powder gas flows in casting metallurgy systems were selected. The carrier gas velocity value is taken as the main parameter of the carrier gas flow mode.

One of the main characteristics of a two-phase flow is the mass density of the mixture, which is defined as the ratio of the mass flow rate of the solvent to the mass flow rate of the gas. At that time, gas-rubber mixtures with a mass flow rate of 2 to 60 kg/kg were used for blowing metal.

The critical speed of pneumatic transport was assessed as the main parameter ensuring the reliability of the blowing structure as a whole. One of the main and determining factors influencing the successful operation of injection equipment is the correct choice of the chamber blowing system.

Currently, two types of equipment are used for injection technologies: aeration and pneumatic-mechanical. Aeration-type chamber blowers are used for deep injection of powder materials and partially for reducing torque. In recent years, pneumatic chamber blowers have become increasingly widespread in the world. They are used for twisting stone surfaces, as well as shallow injection of powder materials into metal alloys.

Such blowers have a design more suitable for the operating conditions of metallurgical production in our country, are simple and reliable in operation, and have a wide range of applications. As a result of research and development work for injection metallurgy, a pneumatic-mechanical type design was chosen as a chamber blower [18].

This type of air blower is equipped with a tray dispenser, which is placed horizontally in the lower part of the working chamber. The dispenser has a separator ball wheel, the speed of which is regulated by an electric motor equipped with a frequency converter.

In 2001, the NIM-01-2 injection device for blowing powdered materials into a liquid alloy in an open-hearth furnace was put into operation at the plant in the Russian Federation. Work on the application and development of metal carbonization technology continues here. In 2002, an injection device for tightening pipes of a circulating vacuum cleaner of the NIM-01-4 type was put into operation. A new design was developed, manufactured and launched into production, cutting off the flow of gunite mass with the ability to adjust the angle of dispersion from 30 to 360 degrees for internal gunning of vacuum cleaner pipes. As a result of the device's introduction, the service life of the circulating vacuum cleaner pipes has increased significantly.

IV. Conclusions

1. The transition to innovative metallurgical technologies was systematically analyzed in the context of the priority direction of decarbonization. It was determined that at present the main direction of decarbonization can be considered the rapid development of electrometallurgy. In this direction, blowing liquid metal with oxygen, using physicochemical methods in extra-furnace (ladle furnace) processing, using powerful transformers in electric furnaces, automated control and management of melting, in the processing of synthetic resins. "Swamp" melting in induction furnaces, preliminary heating of slag, and widespread use of injection metallurgical processes were assessed as innovative technologies.

2. Reducing energy costs in the production of electric steel is put forward as the main task of metallurgical technologies. Two main directions of decarbonization in the steelmaking complex are defined: intensification of metallurgical processes based on increasing the capacity of the furnace-transformer and the introduction of modern

This work was carried out with the financial support of the Science Foundation of Azerbaijan – Grant No. AEF-MCG-2023-1(43)-13/01/1-M-01.

YOUNG SPECIALISTS EMPLOYMENT AS A FACTOR OF SUSTAINABLE RURAL DEVELOPMENT

Bella Tokaeva

•

North-Ossetian State University named after Kosta Khetagurov, RUSSIA
bel.to@yandex.ru

Abstract

The paper deals with the problems of employment of young in-demand specialists in rural areas. The development of rural areas is one of the priorities of our time, as there is a noticeable decrease in the number of both the rural population and those employed in public agricultural production. The need to attract young specialists to rural areas is becoming a task of national importance. The employment of young specialists is an important factor in the sustainable development of rural areas, since without young highly qualified personnel it is impossible to develop and bring to a new level the social infrastructure of rural areas and high-tech agriculture. As part of the study of this problem, we conducted a comparative analysis of the level of employment in urban and rural areas. A set of measures is proposed to improve economic, social and migration policy in rural areas in order to attract and retain in-demand specialists.

Keywords: young specialists, employment, rural areas, rural unemployment, living standards of the rural population

I. Introduction

Agriculture in the 21st century is an area of great opportunities. Stable growth of the rural economy contributes to the development of all regions of the country, therefore, solving issues of socio-economic development of rural areas are fundamental to the stable and sustainable development of any country. The agro-industrial complex is one of the priority sectors of the Russian economy. Today the task is to provide agricultural enterprises with the necessary number of competent, qualified personnel capable of organizing high yielding and efficient production. Recently, the land area has more than doubled. Labor productivity has increased due to the use of modern agricultural machinery. At the same time, staffing shortage have been and remain one of the key issues. And although our enterprise is not currently experiencing a large labor shortage, there is no personnel reserve in the farm business [1].

Modern agro-industrial complex is a high-tech industry that requires specialists of new generation. A modern stock-farmer is a highly qualified specialist who knows how to work with special computer programs, analyze data and make competent decisions based on them.

Today, the rural labor market is characterized by a shortage of young specialists in many sectors. The problem is relevant because as the demand for young specialists grows, competition between companies for their selection also increases.

If rural economy degrades, then rural areas do not develop.

II. Methods

In the course of writing this scientific work, we used the researches of Russian economists who made a great contribution to the science on the topic under consideration, as well as articles in periodicals and Internet resources.

Such methods as monographic, comparative and logical analysis, SWOT-analysis were used in the article.

The data of the Federal State Statistics Service and regulations were used as factual and analytical material.

III. Results

The state is taking all measures to support the development of the agro-industrial complex. In 2024 state support for the agro-industrial complex will amount to 558 billion rubles. Since the beginning of the main State program for agricultural development in 2013, more than 3.5 trillion rubles has been allocated to it. Landholders and processors have access to a wide range of support measures available to both large companies and small businesses, which has a positive effect on production output. Alongside with this, 68 billion rubles is envisaged for the comprehensive program for the development of rural areas and 40.7 billion rubles for the land reclamation program. Depending on climatic conditions differentiation of state support for agriculture in different regions of Russia will be preserved. Such differentiation already exists, preferences are provided for various regions, including the Far East, the North Caucasus, the Arctic zone and new territories.

Non-prestigious, low-paid work, mainly its greater part, is hard manual labor; life "without basic amenities" far from the city is the old Soviet stereotype about agriculture, formed by more than one generation, which has led to a paradoxical situation: the high-tech and modern sector of the agro-industrial complex, which is constantly modernizing and developing, introducing IT and other advanced technologies, experiences a constant shortage of personnel today. Decent work is increasingly recognized as an indispensable factor in sustainable development, capable of lifting an individual, his family and community out of poverty. Poverty is a predominantly rural phenomenon. The ILO estimates that in developing countries, more than 80 percent of the poor live in rural areas. In 2012, the rate of extreme poverty in rural areas was four times higher than in urban areas.

The state is interested in the development of the agro-industrial complex, because today this industry is the main source of export revenues. In 2023, the supply of agricultural products abroad in monetary terms amounted to 43.5 billion dollars, including grain exports - 16.5 billion dollars, which is a record value. And the higher the income the country receives from the agricultural sector, the more funds can be directed to the development of rural areas. Attention is also paid to the development of agricultural cooperatives, access to markets is expanded, and assistance is provided in organizing wholesale and retail trade. And the State program "Integrated development of rural areas" helps in this matter. During the period 2020-2025 the state will allocate almost 2.3 trillion rubles to improve the living and working conditions of rural population [2]. Trillions of rubles will be spent on all this. One way or another, the changes should affect 37 million people.

The main goal of State programs is to ensure sustainable development of rural areas. To achieve these goals, it is necessary to:

- conduct a detailed assessment of the real needs for rural development; improve the legal base for providing state support and ensuring the protection of interests,
- develop and more actively implement mechanisms for grant support for rural youth,
- attract investments for the creation and development of non-agricultural enterprises and social infrastructure in villages,
- develop public-private partnerships between local residents, agribusiness, civil society institutions and government agencies;

Rural areas across the Russian Federation are struggling to retain and attract young people for a variety of reasons. The twin demographic trends of youth outflow and population aging make it increasingly important for rural cities to implement youth retention and attraction strategies.

The share of the rural population in the constituent entities of the North Caucasus Federal District (NCFD) exceeds the Russian average indices, in some republics it is twice as high. Thus, as on January 1, 2023, in all seven constituent entities of the Russian Federation that are part of the NCFD, the actual value of the index of "Share of rural population in the total population of the Russian Federation" exceeds the Russian average index (25.1%)", the report says. It is noted that in the Republic of Dagestan the share of rural population is 54.8%, in the Republic of Ingushetia – 45.2%, in the Kabardino-Balkarian Republic – 48.2%, in the Karachay-Cherkess Republic – 58.6%, in the Republic of North Ossetia-Alania – 36.8% (see Table 1), in the Chechen Republic – 61.9%, in Stavropol Territory – 39.3% [3].

Table 1: *Population of North Ossetia by municipal districts and towns*

Region	2017	2018	**2019**	**2020**	**2021**
Ardonskiy MD	31 705	31 796	31 830	31 755	31 825

*MD – municipal district

The state is developing strategies to attract and retain young people, assessing not only federal, but also regional factors. Over two years, almost 340 million rubles have been issued as part of a regional project to support farmers and develop rural cooperation in North Ossetia. The Cabinet of Ministers has made amendments to the rules for granting subsidies. The support was provided to 150 farms and cooperatives for the period of 2022-2023. Thus, farmers get an opportunity to expand their production; the volume of local products that reach the shelves increases and, accordingly, food security increases. Another issue is the development of the agro-industrial complex. This year, 215 million rubles have been allocated for the activities of the national project to support farmers and develop rural cooperation. This is 85 million rubles more than last year. In terms of the volume of allocated funds, North Ossetia-Alania is among the leaders in the country. Nevertheless, there are still a lot of drawbacks in the NCFD, i.e. a lot of manual labor, where you have to deal with animals and crops, working hours, which do not coincide with the working period, work greatly depending on natural factors, and, in addition, the problems of a low level of social and communal infrastructure. So, in August 2023 LLC Agro-Industrial Holding "Master-Prime, Beryozka" required a combine operator with a salary of 20 000 rubles, and with irregular working hours. In 2023, almost 900 thousand tons of grain crops were harvested in North Ossetia. Livestock breeding indicators are very good, both in dairy, poultry and cattle meat. Modern infrastructure and a qualitatively new living environment are being created: new schools, kindergartens, cultural centers, and communal networks.

However, as practice shows, rural areas use available human resources, equipment and technologies only by 50 percent. The remaining 50 percent is the key starting platform and at the same time a problematic growth zone for all Russian agglomerations. Weak economic infrastructure, outdated agricultural equipment and lack of modern technologies hinder the development of agricultural production. But perhaps the biggest problem is the shortage of personnel. Labor resources are moving to other industries, where earnings are higher. Moreover, young people, whose labor is especially needed in the village, are leaving for the cities first of all. The low level of incomes is confirmed by official statistics. According **to** Federal State Statistics Service, in the first quarter of 2024, the average accrued salary in agriculture amounted to 55.6 thousand rubles, while, for example, in the mining industry - 150.3 thousand rubles, in the processing industry - 150.3 thousand rubles, and in the agricultural sector - 150.3 thousand rubles.

Nowadays, one of the main factors constraining the innovative development of the economy, including agricultural production, is the shortage of personnel in the labor market. Now, it is necessary to focus on training a sufficient number of personnel in demand in agriculture, possessing modern competencies and skills for their effective use. Along with the general shortage in the industry, there is an increasingly acute shortage of highly qualified personnel, which is a consequence of the widening gap between the quality of their training and the ever-increasing qualification demands of the business community. For example, some of the most in-demand specialists in the NCFD are veterinary specialists – veterinarians and veterinary paramedics, livestock specialists. Among the working specialties there are vacancies for tractor operators and drivers, and machine milking operators. On average, about 12-15% of the positions of specialists and working professions of the agro-industrial complex remain vacant. For example, the first enterprise in North Ossetia-Alania with a full cycle of milk production and processing, which has its own raw materials, feed base and a milk processing plant for the production of natural dairy products with the brand "Master-Prime, Beryozka" in the village of Khataldon, Alagir district, the following employees were needed: an agronomist (with a salary of 20 000 rubles); veterinarian (with a salary of 20 000 rubles); stock-farmer (with a salary of 15 000 rubles); engineer (livestock engineer - breeder) - salary based on the results of the interview; combine operator (with a salary of 20 000 rubles); tractor operator (mechanizer) (with a salary of 20 000 rubles). Modern agriculture is a high-tech production employing highly qualified people.

According to the results of 2020–2022, about 65 thousand workplaces were created through the activities of the State program and additional investment projects [10]. Workplaces in rural areas are also being created as part of the State program for the development of the agro-industrial complex. The creation of a modern farm will ensure crop rotation and increase the yield of our main crop, i.e. soybeans, and will also help to create additional workplaces. Subsidies are provided for the development of family farms, agri-tourism, and cooperative farming. Due to these measures, more than 4 thousand new farms were created, more than 42 thousand farmers were involved in cooperative farming, and more than 10 thousand workplaces were already created in 2023 [3].

In the Nizhny Novgorod region, measures to support the agro-industrial complex and grant programs for farmers have been developed. Various government support measures were provided for agricultural enterprises: subsidies are provided for manufactured products (milk, meat, potatoes, grain, vegetables), subsidies for the purchase of machinery and equipment. There are also programs for favourable credit facilities. Grant programs "Agri-tourism", "Family Farm", "Agri-startup" have been developed for farm business. In total, in 2024, the budget provides 6.1 billion rubles to support the agricultural industry and the development of rural areas, of which 4.2 billion are funds from the regional budget, 1.9 billion are federal subsidies. As part of the "Integrated development of rural areas" program, social payments are provided for rural workers to improve housing conditions. The program also provides for the construction of housing, which the employee signs up under a rental agreement. In this case, housing construction is 80 percent financed from the federal and regional budgets, 20 percent comes from the employer and the municipality. This year under the program 22 houses are being built for rural workers and their families. In addition, within the framework of the regional law on the development of human resources, a payment of one million rubles is provided for young specialists to improve housing conditions.

The following Agricultural Support Programs are in effect in the Russian Federation:

Zemsky (country) teacher is a program that allows young specialists to receive one-time financial support. To attract qualified personnel to villages, the State offers incentive payments for various specialists. Teachers can participate in the Zemsky Teacher program, i.e. an annual competition whose winners are employed in rural schools for 5 years and receive 1 million rubles (or 2 million in the Far East).

According to the Ministry of Education of the Russian Federation despite the record number of program participants, the need for teaching staff in villages is still high – there are not enough teachers of mathematics, Russian language, foreign languages and some other subjects.

Zemsky Doctor is a Program to improve housing conditions for doctors under 50 years old, moving to rural areas. The program "Zemsky Doctor" operates for medical workers. Doctors who move to work in a village or small town receive a million rubles, and paramedics, midwives and nurses receive 500 thousand rubles each. In hard-to-reach areas, payments increase to 1.5 and 0.75 million, respectively, and in the Far North and Far East they reach 2 and 1 million rubles, correspondingly.

Data from the Accounts Chamber show that in some regions "zemsky doctors" work only for a short time and then quit. This reduces the effectiveness of the program. The auditors recommended strengthening control over compliance with the terms of labor contracts by participating doctors.

Besides, regions often attract specialists to agriculture through their own programs. Thus, in the Krasnoyarsk Territory, young workers of agricultural complexes can receive a million rubles in two stages – 500 thousand immediately and another 500 in three years (Resolution of the Krasnoyarsk Territory Government No. 198-p).

Rural mortgage is aimed at receiving a preferential loan from 0.1% to 3% for the purchase or construction of housing worth up to 3 million rubles. The maximum loan amount is 6 million rubles for one borrower and 12 million for couples. The initial contribution is 20% of the cost of housing for one borrower and 40% for couples. According to the Ministry of Agriculture, 16 banks including Rosselkhozbank and Sberbank participated in the program at the end of 2023.

The program of allocation of land plots for specialists needed by the village. Teachers, doctors, veterinarians and other necessary personnel can receive land for free use, and after 5 years of work, register it as property. Requirements for the area and location of plots are established by local authorities.

Another housing program is the Family Farm. For example, in the Novosibirsk Region it involves the creation of farm businesses on the basis of preferential land plots. The participant must be a peasant or farm business with 2 or more family members. The number of cattle should not exceed 400 heads, goats/sheep not more than 500 heads of broodstock.

Transport and tax benefits. The benefits associated with owning transport and agriculture are also important. Thus, owners of cars registered in rural areas pay less for a CMTPL insurance policy due to a lower territory coefficient (TC). This is explained by lower traffic intensity in villages.

Besides, citizens who run private subsidiary farms are completely exempt from paying transport tax on agricultural machinery – tractors, combines, milk tankers, etc. To receive the benefit, you need to submit an application to the tax office and an extract from the household book about the farming of private subsidiary farms.

Subsidies are also provided for self-employed farmers, i.e. reimbursement of part of the costs of seeds, feed, veterinary services, etc. The amount of subsidy rates varies from region to region. For example, in the Tyumen region there is a subsidy of 2.15 rubles for each kilogram of milk sold and 3 000 rubles per ton of vegetables and potatoes sold. To receive it, you need to be registered as self-employed and pay self-employment tax.

Labor guarantees and benefits for housing and utilities services. In addition to financial support measures, other benefits are available in rural areas. For example, women working in villages are entitled to a 36-hour work week instead of 40 hours. For exceeding this norm, the employer is obliged to pay extra as overtime.

In addition, once a month, rural women workers can take an additional paid day off at their discretion (Article 262 of the Labor Code of the Russian Federation). It is enough to obtain it by oral or written request of a female employee.

Increased pensions for rural residents. Finally, for those who have worked in agriculture for a long time, a considerable supplementary pension is provided. Non-working pensioners with over 30 years of experience in agricultural production receive a monthly increase of 25% to the fixed insurance pension payment. In 2024 this amounts to 2033.72 rubles.

So, attracting qualified personnel to the region's agriculture is an urgent and main task for the near future. Employers play an important role in staff retention. First of all, they should be interested in retaining specialists, creating favorable conditions for their work and rest, and providing them with decent wages and comfortable housing. To attract highly qualified workers, the Department of agricultural, together with the personnel services of agricultural organizations, currently visit rural schools, hold career guidance meetings, talk about job prospects, and inform about the possibility of concluding contracts for targeted training [3].

The issue of increasing the legal literacy of rural residents is urgent. It is necessary to create educational projects, for example, "Farmer's School", where it will be possible to become acquainted with legal aspects of farming, to improve financial literacy, to create a business model for a future business, to learn the basics of marketing as well as to get acquainted with the latest agricultural technologies and crops.

All young specialists are provided with social benefits stipulated by legislation (incentive payments, housing in the first place). Creating decent working conditions is only part of the work being done. It is important to know in what conditions young professionals live, to help organize their leisure time, to show an active citizenship, and to attract them to a healthy lifestyle. Then a number of issues related to retention of human resources in rural areas and many others will be resolved more easily. These issues are closely monitored by the government agencies. Monitoring of compliance with legislation in relation to young professionals and workers is carried out regarding the provision of vacations, compliance with work and rest regimes, compensation. If the approach is right, rural businesses can successfully attract and hire the best specialists.

Many agro-industrial complexes pay for staff training at universities and colleges, as well as training on advanced training courses in the central regions of our country [4].

Within the framework of the national project "Science and Universities", scientific and educational centers with an agricultural profile are created as functional units to ensure the scientific and technological transfer of the results of intellectual activity, youth laboratories that are engaged in research in the field of agricultural sciences are formed. Thus, the Far East State Agrarian University and the agricultural enterprise Dimskoye are currently working on a project aimed at creating a new Amur cattle breed adapted to local conditions. North Caucasus Federal University is expanding scientific projects related to the agro-industrial complex. For example, these are "smart greenhouses" for growing vegetables using robots. Such robotic assistants can plant, care for plants, and deliver crops to the warehouse. A robotic tomato grower with a pattern recognition system has already been created. It is able to determine the maturity of tomatoes and the need for their timely harvesting. In one medium-sized greenhouse, from 30 to 60 mechanical agrobots can work. In addition, NCFU scientists also work on the creation of organic fertilizers from low-value agricultural waste in collaboration with colleagues from other countries – Turkey, Iran and Uzbekistan [5]. In the food industry, healthy food products enriched with micro- and macroelements are being developed. One of the largest projects is the joint implementation with the Stavropol milk-processing plant of the first lactose (milk sugar) technology in Russia. This project is being implemented to replace the import of functional dairy ingredients for the medical, children's and veterinary industries. Modern digital solutions allow to significantly increase the economic indicators of agricultural areas. For example, Earth remote sensing data from space had already been successfully applied to identify possible risks and forecast crops. Major Russian agro-industrial enterprises are actively using solutions based on Internet of Things (IoT) and big data technologies. They enable farmers to obtain real-time information on temperature, humidity, soil condition and soils from each individual plot of land.

It is necessary to further develop the educational process from a model that primarily implements an educational function to a model that implements educational, research and technological functions [6].

It is also important to consider subjective factors that may not have been considered by previous generations, such as the ability to maintain a work-life balance, access to arts, culture, social and recreational opportunities, and fostering a sense of belonging to a place. If a business is focused only on making as much money as possible, without paying attention to social issues and without solving the problems of the territory in which it operates, sooner or later people will start to leave this territory. Besides work, young people need comfortable housing conditions, which in rural areas should be the same as in the city. In addition, employees of agricultural enterprises should be provided with health resort treatment, which could be obtained at the expense of the employer.

However, this problem can be solved in different ways:

• organization of a leisure center;
• creation of youth clubs;
• opening of sports and art clubs.

The social sphere at any time is the most susceptible to changes in the economic situation in the country [6].

Our study focused on young people (136 people from the villages of Elkhotovo and Zamankul) aged 23 to 30 years. The survey was used to collect data for subsequent assessment of the factors that youth face when deciding to stay or leave a particular village.

Thus:

1) 42% of participants expressed their desire to stay in their villages
2) 58% of young respondents named “work” as the main reason that they are going to leave
3) 61% noted Moscow and Krasnodar when asked where exactly those young people intended to migrate
4) respondents indicated the following reasons why they do not leave: “there are opportunities for professional growth”, “family circumstances”, “like the village”

Our research also showed the following values that would attract young people to rural communities:

1. Stable employment,
2. Work-life balance,
3. Digital information on the availability of culture/sports and recreational opportunities.

Our study results support the literature by indicating that youth's sense of belonging and perceptions of their home community may play an important role in their decision to stay or return to rural areas. The importance of “birthplace” (small homeland) is crucial when developing strategies for retaining and attracting young people [7].

Agricultural regions often have a reputation for being isolated and behind the times. In fact, many rural areas are home to businesses that are at the forefront of innovation. However, these businesses often find it difficult to attract and retain talent. This is partly due to the perception that job opportunities are limited in rural areas.

Businesses in rural areas need to offer higher wages and benefits than their urban counterparts to attract and retain young employees. There are also fewer job opportunities in rural areas, so workers are more likely to leave a company if they don't feel they are being paid a decent salary. To compete for talent, businesses in rural areas must offer wages and benefits at least at the level of urban areas [8]. In today's economy, it is more important than ever that businesses provide opportunities for career growth and development. By doing so, rural businesses can gain a competitive advantage.

Finally, businesses in rural communities need to focus on creating a positive working environment. This can be achieved by making sure the physical working environment is clean and comfortable and the company culture is the one that values teamwork, respect and communication. By creating a positive working environment, businesses in rural communities can ensure that they are able to attract and retain young workers.

Today, rural regions offer a unique set of challenges and business opportunities. By creating an environment that meets employee needs, businesses can increase their chances for attracting and retaining top specialists [9].

Most studies have shown that employees who feel stuck in an unpromising job are much more likely to leave their current position. Moreover, employees who don't feel like they're learning and growing are more likely to become disengaged and unproductive. On the other hand, employees who feel they have opportunities for career growth and development are more likely to be loyal and productive. Therefore, businesses need to provide opportunities for career growth and development. By doing this, companies will be able to retain their best employees and attract new talent.

Nowadays, there are all prospects for rural areas to become modern, comfortable, economically developed and promising ones. These are villages where the population has a job with decent pay, a school and a kindergarten, housing, and where social, sports and cultural life is supported. It is a village you will never leave.

IV. Discussion

In modern Russia, the employment picture is rapidly changing (entrepreneurship, remote work, etc.) Combined with the abilities of the younger generation as a tech-savvy cohort concerned with work-life balance, it is rural areas that can meet the needs of these young professionals in creating dynamic, prosperous places for both work and life:

- Provide quality vocational education and training and practical skills. Access to the labor market should be ensured through advanced training of employees and managers in vocational training and advanced training centers in agriculture.
- Promote the introduction of learning concepts divided into modules, with a focus on learners, as well as improved teaching methods (such as hybrid or e-learning models) and the creation of enterprises in agriculture (so-called agricultural enterprise) [8].

Thus, the importance of the agricultural sector as a potential source of employment is emphasized and various initiatives and reforms are encouraged to address this problem. It is important to highlight the need for targeted measures such as skills development, vocational training and economic empowerment of youth, as well as measures to stimulate workplace creation and promote sustainable development. Finally, there is a need for a holistic approach to solving the problem of rural unemployment, which combines both federal and regional efforts to stimulate inclusive growth and improve the well-being of rural communities.

Breaking away from the traditional employee-employer relationship by expanding employment opportunities, where remote work, self-employment and participation in new employment sectors offer rural areas more opportunities to attract potential residents. The importance of highlighting the balance between quality of life and employment can expand opportunities for young people considering making rural communities their home for the long term [10].

However, public services, transport and information and communication capabilities are still underdeveloped in rural areas. Employment is a decisive factor for young people to move, but it is not enough to maintain sustainable development of the territories in the long term. While cities are becoming increasingly inaccessible due to the high cost of living, rural areas provide an opportunity to realize one`s own creative and business ideas.

Abstract

The modern market environment is characterized by a high degree of uncertainty, fluctuations in supply and demand, as well as the influence of various external factors, such as inflation, currency fluctuations and legal changes. In these conditions, the enterprise must develop effective strategies to protect its financial, material and intellectual resources. In practice, economic security is implemented through a set of measures aimed at protecting capital, increasing the financial transparency and improvement of operational efficiency. A set of measures to ensure economic security allows you to minimize potential risks and strengthen the company's position in the market.

Keywords: economic security, enterprise security, financial security, market economy, risks, microeconomics

I. Introduction

The modern market economy is characterized by an unstable state, which is expressed in serious fluctuations in the exchange rate, economic growth, inflation and unemployment. This state of the economy can be caused by various factors, including global economic crises, political instability, conflicts, natural disasters, etc. This makes it difficult to develop business strategies, financial planning, and make long-term investment decisions.

The business climate is becoming less attractive to investors, which can lead to a slowdown in economic growth, increased unemployment and increased social tensions. Thus, global economic uncertainty has a serious impact on the stability of the social system and forces governments to develop measures to stimulate business processes, regulate inflation, reduce unemployment and improve the investment climate in the country.

One of the most important tasks of companies in an unstable market economy is to ensure their own economic security. Economic security of an enterprise is a complex concept that has both a substantive and functional interpretation. From a substantive point of view, economic security is characterized as the ability of a company to maintain its economic stability and profitability in the face of uncertainty and risk. From a functional point of view, economic security is a set of measures aimed at supporting the stable functioning of a company in conditions of economic instability and ensuring cost reduction, increased profitability and protection from external and internal threats [6].

II. Methods

Mechanisms for ensuring the economic security of an enterprise are a system of measures and tools aimed at protecting the enterprise from internal and external threats that can jeopardize its stable functioning and financial stability. These mechanisms play a key role in maintaining the competitiveness of economic entities in a dynamic market environment, they ensure the stability of income and profits, help to maintain investment attractiveness and a good reputation in the market.

The system of ensuring the economic security of an enterprise in a market economy is presented in Fig.1.

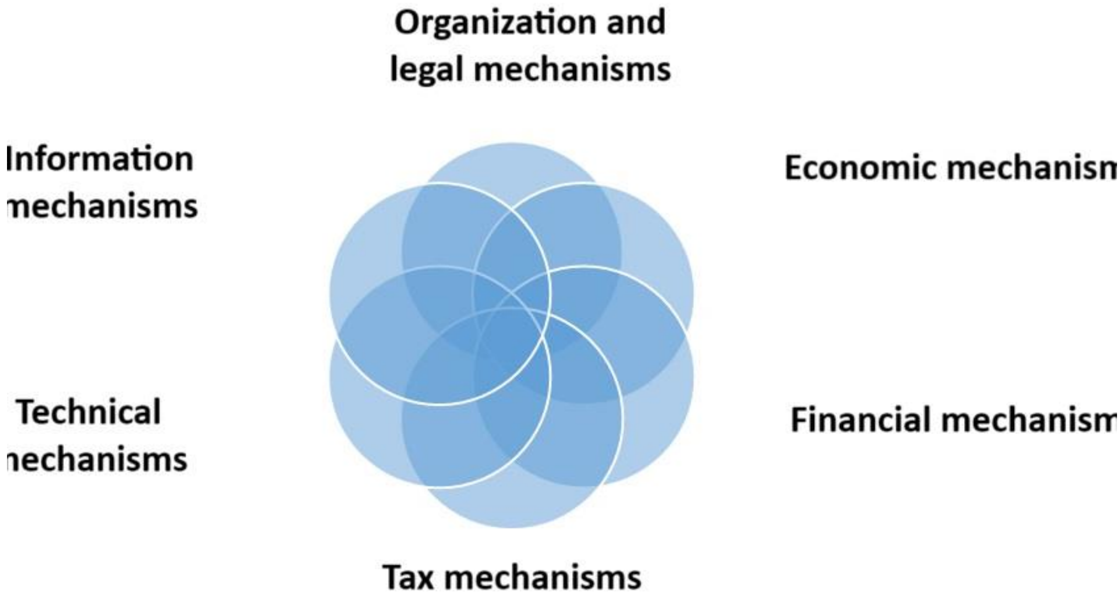

Figure 1: *Mechanisms for ensuring the economic security of the enterprise [6]*

Organizational and legal mechanisms for ensuring economic security are a set of measures aimed at creating a stable legal framework and management system that minimizes external and internal threats to the activities of the enterprise. The system of legal mechanisms for ensuring the economic security of an economic entity includes four levels:

- federal regulatory legal acts (the Constitution of the Russian Federation, the Civil Code of the Russian Federation, the Tax Code of the Russian Federation, the Labor Code of the Russian Federation, Federal Law No. 390-FZ of December 28, 2010 "On Security" and others);
- regional regulations (laws and regulations governing investment, tax and other aspects of the functioning of enterprises in the region);
- municipal regulatory legal acts (resolutions regulating the procedure for taxation by local taxes, the location of retail outlets and municipal support for small and medium-sized businesses);
- corporate regulatory legal acts (charter, internal regulations, staffing table, internal labor regulations, job descriptions, accounting policy, orders of the head, etc.).

Organizational mechanisms for ensuring the economic security of an economic entity can be differentiated by the frequency of their implementation into one-time, as well as implemented as necessary, periodically and systematically. An example of a one-time event is the development of the company's charter and other constituent documents that are formed at the stage of its foundation. Also, one-time mechanisms include the establishment of key internal procedures and regulations - anti-corruption policy, economic security policy, data privacy policy. Organizational measures for crisis management are implemented when the company faces financial difficulties or a sharp change in market conditions.

III. Results

Periodic organizational measures to ensure economic security include the distribution of encryption keys, tax audits, training of employees on security and compliance with corporate standards, revision and renewal of contracts with key partners to assess the relevance of the terms of cooperation. On an ongoing basis, companies monitor financial performance, assess business risks and control compliance with internal regulations for ensuring economic security.

An important aspect of ensuring economic security is the introduction of a corporate culture that contributes to the formation of a conscious attitude among employees to the issues of economic security. Supporting corporate values and stimulating responsible behavior of employees at all levels helps to strengthen loyalty and reduce the likelihood of information leakage, unauthorized actions and other internal violations.

Economic mechanisms for ensuring security make it possible to determine the strategic directions of the enterprise's development, as well as to form an effective system of financial, production and marketing management. They also allow to optimize production processes and reduce costs, which in turn increases the competitiveness of an economic entity in the market and ensures its security in an unstable economy [3]. Ensuring a stable position in the market requires the enterprise to constantly adapt to changing environmental conditions, primarily through the production of competitive products. The solution of this problem involves tracking consumer preferences, introducing innovative solutions, optimizing the use of material, human and financial resources.

Regular marketing research helps to reduce uncertainty in the process of making management decisions and allows you to determine the most promising directions for the development of the enterprise in a market economy. Reputation and brand management plays an important role in ensuring economic security, as a positive image of the company protects it from the negative influence of external factors. Consumer loyalty, formed through marketing activity and high product quality, reduces the sensitivity of the company to short-term economic shocks and helps to function stably in the market.

The lean manufacturing system includes three key subsystems, the interaction of which is based on the use of the tools of classical and flexible project management: "Management", "Production Organization" and "Continuous Learning". Each of the listed subsystems corresponds to a certain set of lean manufacturing methods. The most common lean manufacturing methods are Kaizen, 5S Technique, Rapid Equipment Changeover (SMED), TPM System, 5 Whys, Visualization, Fishbone Diagram, and many others. It should be noted that lean manufacturing methods demonstrate particular relevance when it is necessary to ensure business sustainability in the face of economic uncertainty. maintaining stability and improving the company's activities in conditions of economic uncertainty.

The introduction of automated control systems in production makes it possible to ensure the accuracy, flexibility and efficiency of production process management, minimize the impact of the human factor, and increase productivity and product quality. The listed optimization tools create a significant margin of safety for the enterprise, reducing its dependence on market fluctuations.

The key financial mechanism for ensuring the economic security of the enterprise is the formation of an effective financial management system, including budget planning, accounting and analysis of financial indicators, monitoring and control over the implementation of financial plans. The effectiveness of this mechanism is based on a comprehensive assessment of the current state and effectiveness of the company's activities using a variety of financial indicators - economic potential, profitability, liquidity, financial stability, profitability and business activity. The main source of information for the analysis of the financial and economic activities of the enterprise is the data of accounting (financial) statements, especially the balance sheet and the statement of financial results.

An integral structural component of financial planning is the formation of a financial strategy that allows the enterprise to ensure financial stability and efficiency.

The development and implementation of the financial strategy of the enterprise require an integrated approach and close integration with the overall development strategy of the organization. This allows you to effectively manage financial resources, reduce risks and ensure sustainable growth in a dynamically changing external environment.

Tax mechanisms for ensuring the economic security of an enterprise are a set of measures aimed at minimizing tax risks and ensuring compliance with tax legislation. Such mechanisms include, first of all, tax planning – the process of developing and implementing strategies to optimize the company's tax liabilities within the framework of the current legislation. and maximum use of tax benefits, deductions and other benefits provided for by law.

One of the most common tools for tax optimization is the use of tax benefits provided for by law. For example, from 2021 to 2023, the income tax rate for Russian IT companies was 3%, and in 2024 it was reduced to 0%. To receive this benefit, a company must be accredited by the Ministry of Digital Development of the Russian Federation, and income from the sale of IT products and services must be at least 90% of its total revenue. In many innovative industries, enterprises can use increased depreciation coefficients to reduce the amount of taxable profit.

The choice of the legal form of the company can significantly affect tax liabilities. For example, legal entities and individual entrepreneurs are taxed at different rates and methods, which allows you to choose the form depending on the volume and types of activity. In addition, holding structures allow you to distribute profits and losses between subsidiaries, which makes it possible to optimize tax payments in a group of companies. Many states offer special tax regimes for small and medium-sized businesses or certain sectors of the economy. For example, the simplified taxation system (STS) in Russia allows small businesses to pay a lower tax at a rate of 6% of income or 15% of the difference between income and expenses, while insurance premiums paid for employees are deducted from the tax amount. It also provides for a patent taxation system and a single agricultural tax, which significantly reduce the tax burden for the relevant types of activities.

IV. Discussion

As part of tax planning, companies can reinvest profits in business development, which allows them to reduce the tax base and postpone the payment of taxes to a later period. For example, profits can be used to finance new projects, modernize production facilities or expand the range of products. This tool reduces the amount of taxable profit and contributes to the growth of the company. Some companies use offshore jurisdictions or countries with low tax rates to register their subsidiaries or store assets.

The economic security of the enterprise also supports the use of measures to ensure the safety of property from man-made accidents, fires and intruders. Security and fire alarm systems ensure the safety of the enterprise, protecting it from unauthorized access and preventing damage from fires.

The company's security software includes a wide range of solutions aimed at protecting against cyber threats, data leaks and other risks that threaten information resources and business infrastructure (Fig. 2).

Antivirus software protects against viruses, malicious code, and spyware. Intrusion detection and prevention systems (IDS/IPS) provide network monitoring and detection of suspicious activity. Security information and event management (SIEM) systems aggregate and analyze security data from a variety of sources to help identify and respond to incidents in real time. Data protection tools (DLP systems) prevent unauthorized leakage and access to confidential information. Anti-spam and email protection programs fight phishing attacks, spam, and viruses that are distributed through email services.

Information mechanisms for ensuring the economic security of an enterprise are a set of measures and methods for the protection, processing and analysis of information aimed at preventing threats to economic stability and protecting confidential data of the company. Unlike technical mechanisms, information mechanisms are focused on the creation, processing and use of data that ensure the sustainable development of the company, prevent risks and increase the management efficiency.

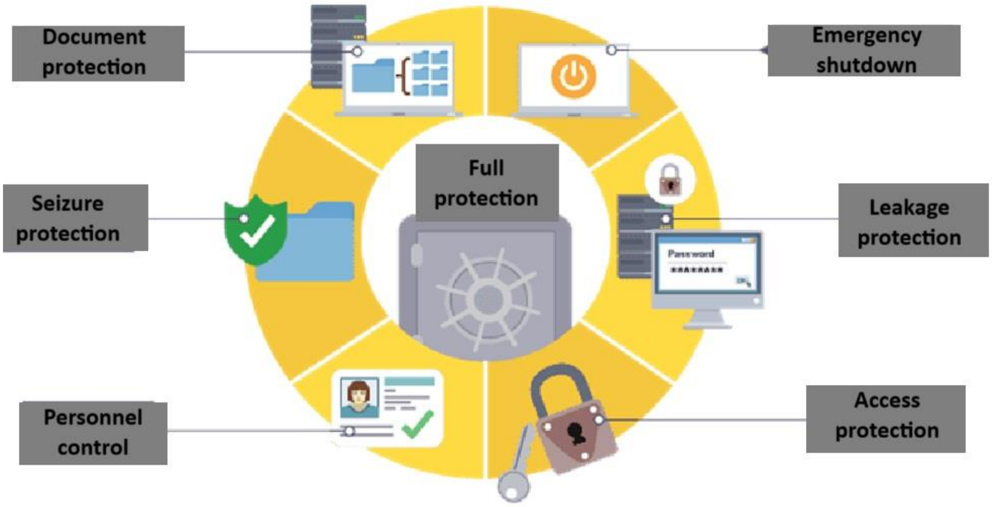

Figure 2: *Company security software*

Thus, the mechanism for ensuring the economic security of an enterprise is a set of organizational, economic, legal, technical and other measures aimed at reducing risks and ensuring the financial stability of the enterprise in conditions of uncertainty and competition in the market. It includes a comprehensive assessment of the economic situation, identification of threats and risks, analysis of the financial condition of the enterprise, management of financial flows, optimization of tax and personnel policies, control over resources and risks, as well as the development and implementation of a risk management strategy.

To implement the mechanism for ensuring the economic security of the enterprise, it is necessary to use modern methods of risk management, such as methods of modeling and analysis of financial flows, analysis of statistical data, as well as information and analytical systems. In addition, it is necessary to comply with legal and regulatory requirements, audit and control the financial activities of the company, as well as organize a system of training and advanced training of personnel.

In general, the mechanism for ensuring the economic security of a company is an important element of its long-term stability and success in the market. It allows you to prevent financial risks and ensure the competitiveness of business in an unstable economy.

ECOLOGICAL MINDSET IN EDUCATION: INTEGRATING SUSTAINABLE PRACTICES INTO EDUCATIONAL PROGRAMS

Elena Arbuzova, Natalia Alexandrova

•

Dostoevsky Omsk State University, RUSSIA
arbuzova-elena@mail.ru

Abstract

This paper delves into the critical role of ecological thinking in education and its potential to drive sustainable practices within educational programs. It begins by defining the concept of an ecological mindset, highlighting its significance in shaping a generation that is more aware of and responsive to environmental challenges. The paper discusses the theoretical foundations of ecological thinking, drawing from environmental psychology, sustainability studies, and educational theory to establish a comprehensive framework for integrating sustainability into educational curricula. Key strategies for embedding sustainable practices in educational programs are explored, including the use of interdisciplinary approaches that connect environmental issues with various subjects such as science, social studies, and the arts. The paper emphasizes the importance of experiential learning, where students engage in hands-on activities, community projects, and real-world problem-solving scenarios, fostering a deeper understanding of ecological principles. Through the examination of case studies from various educational institutions, the paper identifies best practices in implementing sustainability-focused curricula, showcasing successful initiatives and innovative teaching methods. Additionally, it addresses the challenges educators face in integrating ecological thinking into existing programs, such as curriculum constraints, lack of resources, and varying levels of institutional support.

Keywords: ecological mindset, education, sustainable practices, educational programs, interdisciplinary approaches, experiential learning, environmental awareness, curriculum development, sustainability education, best practices

I. Introduction

In recent decades, the urgency of addressing environmental challenges has escalated dramatically, driven by the alarming consequences of climate change, biodiversity loss, and resource depletion. As the world grapples with these pressing issues, the role of education in fostering an ecological mindset becomes increasingly critical. An ecological mindset encompasses a way of thinking that prioritizes sustainability, environmental stewardship, and an understanding of the interconnections within ecosystems. It empowers individuals to recognize their role in contributing to environmental health and encourages proactive engagement in sustainable practices.

Education serves as a powerful catalyst for instilling this mindset, shaping attitudes, values, and behaviors from an early age. By integrating sustainable practices into educational programs, institutions can equip students with the knowledge and skills necessary to navigate and address complex environmental challenges. This approach not only enhances students' understanding of ecological principles but also fosters a sense of responsibility and agency, motivating them to make informed choices that positively impact the environment.

Despite the growing recognition of the importance of ecological thinking in education, many educational institutions continue to prioritize traditional curricula that often overlook sustainability principles. This oversight limits the potential for students to engage meaningfully with environmental issues and undermines efforts to cultivate a generation of environmentally literate individuals. Therefore, it is imperative for educators and policymakers to actively seek ways to incorporate sustainability into educational frameworks.

This paper aims to explore the integration of ecological thinking into educational programs, examining effective strategies and best practices that facilitate this process. It will review theoretical perspectives on sustainability in education, highlight innovative pedagogical approaches, and present case studies that exemplify successful integration of ecological principles within curricula. By providing a comprehensive analysis of the current landscape of sustainability in education, this paper seeks to contribute to the ongoing discourse on fostering an ecological mindset among students and promoting sustainable practices within educational settings.

Ultimately, the goal is to inspire educators, administrators, and policymakers to recognize the transformative potential of ecological thinking in education and to take proactive steps towards embedding sustainability in their programs. As the world faces unprecedented environmental challenges, the need for a generation equipped with an ecological mindset has never been more urgent.

II. Methods

This study utilizes three primary methods to investigate the integration of ecological thinking and sustainable practices into educational programs: literature review, surveys, and case studies. Each method is detailed below with examples to illustrate its application.

1. Literature Review

The literature review serves as the foundational method for this study, providing a comprehensive analysis of existing research related to ecological thinking in education. This includes examining theoretical frameworks, pedagogical strategies, and empirical studies that highlight effective practices and challenges in sustainability education.

Example:

- The review may include key works such as “Education for Sustainable Development: A Guide for Educators” which outlines strategies for embedding sustainability in curricula and teaching practices.
- Additionally, studies documenting successful programs, like the Eco-Schools program, which integrates environmental education into schools globally, will be analyzed to extract best practices and lessons learned.

2. Surveys

Surveys are employed to collect quantitative data from educators across different educational levels. This method assesses the current state of ecological thinking in curricula and identifies barriers faced by educators in implementing sustainable practices.

Example:

- A survey could be distributed to teachers in primary, secondary, and higher education institutions, including questions such as:
  - o “How frequently do you incorporate sustainability topics into your lessons?” (Responses: Never, Occasionally, Often, Always)
  - o “What challenges do you face when trying to integrate ecological thinking into your curriculum?” (Response options might include lack of resources, insufficient training, or limited administrative support.)
- The collected data can then be analyzed statistically to reveal trends and correlations between educators' perceptions and the integration of sustainability practices.

3. Case Studies

Case studies provide in-depth qualitative insights into specific educational institutions that have successfully integrated ecological thinking into their programs. This method highlights innovative practices, strategies employed, and outcomes achieved.

Example:

- A case study might focus on a university that has implemented a Sustainability Studies program. This case would detail:
  - The curriculum changes made to include sustainability concepts across various disciplines (e.g., integrating environmental science into business courses).
  - Interviews with faculty and students about their experiences and perceptions regarding the program's impact on awareness and behavior related to sustainability.
  - Assessment of student projects that contribute to local environmental initiatives, demonstrating practical applications of ecological thinking.

Conclusion

These methods—literature review, surveys, and case studies—complement each other, providing a holistic view of the integration of ecological thinking in educational programs. By leveraging quantitative and qualitative data, the study aims to identify effective practices, barriers, and opportunities for fostering sustainability in education.

III. Results

Environmental education involves learning about the environment while gaining the knowledge, skills, values, and attitudes essential for understanding and tackling environmental challenges. It is vital for cultivating responsible and informed citizens capable of making sustainable decisions. With urgent environmental issues like climate change, pollution, and biodiversity loss becoming more prominent, the significance of environmental education is increasingly critical.

Strategies for Fostering a Sustainable Mindset

Integrating Environmental Education into the Curriculum

A highly effective approach to nurturing a sustainable mindset is the incorporation of environmental education into various subjects within the curriculum. This can encompass disciplines such as science, geography, social studies, and literature, covering topics like ecosystems, renewable energy, waste management, and conservation. By weaving environmental themes throughout the curriculum, students gain a well-rounded understanding of environmental issues and their potential solutions.

Hands-On Learning Experiences

Experiential learning serves as a potent method in environmental education. Engaging in hands-on activities such as field trips, nature walks, and outdoor classrooms allows students to make direct connections with their environment. These experiences may involve visits to nature reserves, botanical gardens, and sustainable farms. Through such hands-on learning, students can witness ecological processes firsthand, grasp the effects of human actions on the environment, and cultivate a deeper appreciation for nature.

Sustainable School Practices

Establishing sustainable practices within schools sets a strong example for students. Initiatives like recycling programs, energy conservation efforts, water-saving measures, and the use of eco-friendly materials contribute to this goal. Schools can also develop green spaces, such as gardens and outdoor learning areas, where students can interact with nature and learn about sustainable agriculture and biodiversity.

Project-Based Learning

Project-based learning (PBL) encourages students to explore real-world environmental issues and devise practical solutions. Projects might include developing a school recycling program or crafting a plan to reduce the institution's carbon footprint. PBL not only deepens students' understanding of environmental challenges but also hones their critical thinking, problem-solving, and collaborative skills.

Collaborations and Partnerships

Partnerships with environmental organizations, local communities, and government agencies can significantly enhance environmental education. Schools can collaborate with these entities to offer students expert knowledge, resources, and opportunities for community engagement. Such partnerships may also support involvement in environmental campaigns, clean-up initiatives, and conservation projects.

Incorporating Technology and Innovation

Technology plays a crucial role in environmental education. Digital tools and platforms can deliver interactive and engaging learning experiences. For instance, virtual simulations may illustrate the effects of climate change, while online resources provide current information on environmental issues. Furthermore, encouraging students to innovate and create eco-friendly technologies fosters a culture of sustainability and creativity.

IV. Discussion

One of the most impactful ways to cultivate a sustainable mindset is through the integration of environmental education across the curriculum. This can be applied in various subjects, including science, geography, social studies, and literature. Lessons can encompass themes such as ecosystems, renewable energy, waste management, and conservation. By weaving environmental topics into the educational framework, students can gain a holistic understanding of environmental challenges and potential solutions.

Experiential learning is an effective approach in environmental education. Engaging students in hands-on activities—like field trips, nature walks, and outdoor classrooms—enables them to connect with the environment in a tangible way. These experiences may include excursions to nature reserves, botanical gardens, and sustainable farms. Such immersive learning allows students to witness ecological processes directly, comprehend the effects of human activities on the environment, and develop a greater appreciation for nature.

Establishing sustainable practices within the school environment serves as a powerful model for students. This could involve initiatives such as recycling programs, energy-saving measures, water conservation strategies, and the use of eco-friendly materials. Additionally, schools can cultivate green spaces, like gardens and outdoor learning areas, where students can interact with nature and learn about sustainable agriculture and biodiversity.

Project-based learning (PBL) motivates students to explore real-world environmental issues and create practical solutions. Projects can vary from designing a recycling program for the school to developing a strategy for minimizing the school's carbon footprint. PBL not only deepens students' understanding of environmental matters but also enhances their critical thinking, problem-solving, and collaboration abilities.

Collaborating with environmental organizations, local communities, and government bodies can significantly enrich environmental education. Schools can work with these entities to provide students with expert insights, resources, and opportunities for community engagement. These partnerships can facilitate involvement in environmental campaigns, clean-up initiatives, and conservation projects.

Technology plays a crucial role in enhancing environmental education. Digital tools and platforms can offer interactive and engaging learning experiences. For instance, virtual simulations can illustrate the effects of climate change, while online resources can provide current information on environmental topics. Furthermore, encouraging students to innovate and develop eco-friendly technologies fosters a culture of sustainability and creativity.

Environmental education fosters awareness of environmental issues and their global implications. Students learn about the interconnectedness of natural systems and the effects of human actions on the environment. This awareness is crucial for cultivating a sustainable mindset and promoting responsible behavior.

Development of Critical Thinking Skills

Addressing environmental challenges requires critical thinking and problem-solving capabilities. Environmental education prompts students to analyze complex issues, consider diverse viewpoints, and formulate innovative solutions. These skills are essential not only for environmental stewardship but also across various life contexts.

Promotion of Sustainable Practices

By engaging with sustainability concepts, students are more inclined to adopt eco-friendly practices in their daily lives. This may involve reducing waste, conserving energy, choosing sustainable products, and supporting environmental initiatives. As students embrace sustainable habits, they can influence their families and communities, amplifying the positive effects.

Preparation for Future Careers

The increasing emphasis on sustainability is creating new career paths in areas like renewable energy, environmental science, and sustainable development. Environmental education equips students with the requisite knowledge and skills for these careers, fostering a passion for the environment that drives them toward professions that contribute to a sustainable future.

Improved Health and Well-Being

Engagement with nature has been linked to numerous health benefits, including reduced stress, enhanced mood, and improved cognitive function. Environmental education often incorporates outdoor activities, allowing students to reap these benefits. Additionally, learning about healthy eating and sustainable agriculture can promote better lifestyle choices.

Empowerment and Civic Engagement

Environmental education empowers students to take action on pressing environmental issues. By equipping them with knowledge and skills, it encourages active participation in their communities and advocacy for positive change. This civic engagement is vital for fostering collective efforts toward sustainability.

Incorporating environmental education into various aspects of learning is essential for developing a sustainable mindset among students. Through comprehensive curriculum integration, hands-on experiences, and sustainable school practices, we can prepare future generations to address environmental challenges effectively. By promoting awareness, critical thinking, and sustainable practices, we empower students to become engaged citizens committed to creating a more sustainable world.

Fostering a sustainable mindset through environmental education is essential for preparing students to address the environmental challenges of the future. As climate change, pollution, and biodiversity loss become increasingly pressing issues, it is crucial for educational institutions to equip students with the knowledge, skills, and values necessary to understand and tackle these challenges.

One of the foundational strategies for promoting a sustainable mindset is the integration of environmental education into various subjects. This approach ensures that students encounter environmental themes across the curriculum, allowing them to make connections between disciplines. For instance, science classes can explore ecosystems and renewable energy, while social studies can address the socio-economic implications of environmental degradation. Literature classes can analyze texts that reflect environmental themes, encouraging students to think critically about the narratives surrounding nature and sustainability. By embedding these topics into the curriculum, educators can help students develop a comprehensive understanding of environmental issues and their potential solutions.

Experiential learning is a powerful method for deepening students' engagement with environmental concepts. Hands-on activities such as field trips to nature reserves, community gardens, and sustainable farms allow students to connect with the environment in a meaningful way. For example, a class visit to a local wetland can provide firsthand experience of biodiversity and ecosystem dynamics. Nature walks can encourage observation and reflection on local flora and fauna, fostering a deeper appreciation for the natural world. Outdoor classrooms can serve as spaces for interactive learning, where students can participate in ecological monitoring, gardening, or conservation efforts. These experiences not only enhance knowledge but also cultivate a sense of responsibility toward the environment.

Schools can set powerful examples by implementing sustainable practices on their campuses. Initiatives such as recycling programs, energy conservation efforts, and the use of eco-friendly materials demonstrate the school's commitment to sustainability. Schools can create green spaces, including gardens and outdoor learning areas, where students can engage with nature and learn about sustainable agriculture and biodiversity. Moreover, schools can host workshops and events focused on sustainability, such as tree-planting days or clean-up drives. By fostering an environmentally friendly culture, schools encourage students to adopt sustainable habits that they can carry into their personal lives.

Technology plays a significant role in enhancing environmental education. Digital tools and platforms can facilitate interactive and engaging learning experiences. For example, virtual simulations can help students visualize the impacts of climate change on ecosystems, while online resources can provide current information on pressing environmental issues. Additionally, incorporating coding and robotics into environmental education can encourage students to design innovative solutions to sustainability challenges. By integrating technology into the learning process, educators can make environmental education more relevant and engaging for students.

Collaborating with environmental organizations, local communities, and government agencies can significantly enrich the environmental education experience. Schools can partner with these entities to provide students with expert insights, resources, and opportunities for community involvement. These partnerships can facilitate participation in environmental campaigns, clean-up initiatives, and conservation projects, allowing students to apply their learning in real-world contexts. For example, a partnership with a local conservation group might allow students to participate in habitat restoration efforts, reinforcing the importance of stewardship and active citizenship.

Project-based learning encourages students to engage with real-world environmental issues and develop practical solutions. Projects can range from designing a school recycling program to creating a plan for reducing the school's carbon footprint. PBL not only enhances students' understanding of environmental issues but also develops critical thinking, problem-solving, and collaboration skills. For instance, a project focused on reducing waste in the school cafeteria can involve students researching waste management strategies, conducting surveys, and presenting their findings to school administrators. This hands-on approach fosters a sense of ownership and accountability among students, motivating them to make a tangible difference.

Environmental education raises awareness about environmental issues and their global significance. Students learn about the interconnectedness of natural systems and the impact of human activities on the environment. This awareness serves as the foundation for cultivating a sustainable mindset and encourages responsible behavior.

Addressing environmental challenges requires critical thinking and problem-solving abilities. Environmental education encourages students to analyze complex problems, consider multiple perspectives, and develop innovative solutions. These skills are not only essential for environmental stewardship but also valuable in various life contexts.

By learning about sustainability, students are more likely to adopt eco-friendly practices in their daily lives. This can include reducing waste, conserving energy, using sustainable products, and supporting environmental initiatives. As students embrace these sustainable habits, they can influence their families and communities, amplifying the positive effects.

The increasing focus on sustainability is creating new career paths in fields such as renewable energy, environmental science, and sustainable development. Environmental education equips students with the necessary knowledge and skills for these careers while fostering a passion for the environment that drives them toward professions that contribute to a sustainable future.

Engaging with nature has been shown to provide numerous health benefits, including reduced stress, enhanced mood, and improved cognitive function. Environmental education often involves outdoor activities, allowing students to experience these benefits directly. Furthermore, learning about topics such as healthy eating and sustainable agriculture can promote healthier lifestyle choices.

Environmental education empowers students to take action on environmental issues. By equipping them with knowledge and skills, it encourages them to become active participants in their communities and advocates for positive change. This civic engagement is crucial for driving collective efforts toward sustainability.

At KR Mangalam School, one of the top IB schools in the NCR region, the implementation of a holistic approach to education serves as an exemplary model for fostering a sustainable mindset. The school integrates environmental education into its curriculum, offering students diverse opportunities to engage with environmental issues both inside and outside the classroom. Through hands-on learning experiences, sustainable practices, and community collaborations, KR Mangalam School cultivates environmentally responsible and informed citizens. By prioritizing sustainability in education, the school prepares its students to face future environmental challenges with knowledge, confidence, and commitment.

In conclusion, fostering a sustainable mindset through environmental education is crucial for empowering students to tackle future environmental challenges. By integrating environmental themes into the curriculum, providing hands-on learning experiences, and promoting sustainable practices within schools, educators can enhance students' understanding of environmental issues and encourage them to take action. With the support of innovative teaching methods and a commitment to sustainability, schools like KR Mangalam School are leading the way in shaping the next generation of environmentally conscious citizens.

Abstract

This paper provides a comprehensive examination of the role of digital solutions within the frameworks of the circular economy, focusing on their potential to enhance sustainability and resource efficiency across various sectors. As the world grapples with pressing environmental challenges—such as climate change, resource depletion, and waste management—the shift from a linear economy (take, make, dispose) to a circular economy (reduce, reuse, recycle) has become increasingly essential. Digital technologies play a critical role in this transition by facilitating innovative practices that can lead to a more sustainable and resilient economy.

The paper begins with an overview of the circular economy model, detailing its principles, objectives, and the significance of closing the loop in product lifecycles. This section highlights the differences between linear and circular approaches, illustrating the urgent need for systemic change in how resources are utilized and managed. The core of the paper delves into various digital technologies that underpin circular economy practices. Key technologies discussed include the Internet of Things (IoT), which enables real-time monitoring of resources and products, facilitating better inventory management, predictive maintenance, and efficient resource allocation, leading to reduced waste and improved operational efficiency. Blockchain technology provides transparency and traceability in supply chains, allowing businesses to verify the origin and lifecycle of materials, ensuring ethical sourcing and enhancing recycling processes while building consumer trust. Big data analytics plays a significant role by analyzing large datasets to gain insights into consumer behavior and resource usage patterns, crucial for designing products that meet sustainability criteria and for developing strategies to minimize waste. Additionally, artificial intelligence (AI) can optimize production processes and enhance decision-making by predicting demand, improving product design for longevity, and facilitating recycling processes through automated sorting and material recovery.

In summary, our study reinforces the notion that digital technologies are pivotal in enhancing resource efficiency and sustainability within the circular economy. By improving energy efficiency and reducing waste throughout the product lifecycle, these technologies not only contribute to environmental goals but also provide economic advantages. However, to fully realize the potential of digital solutions in CE frameworks, stakeholders must address the associated challenges, ensuring a collaborative and supportive environment for innovation and technology adoption. Ultimately, the integration of digital solutions into circular economy practices can drive meaningful change toward a more sustainable future.

Keywords: eco-friendly practices, innovation, environmental impact, smart technologies, economic opportunities

I. Introduction

The pressing challenges of the 21st century—ranging from climate change and resource scarcity to waste management—have underscored the urgent need for a fundamental transformation in how societies produce and consume goods. Traditional linear economic models, characterized by a "take, make, dispose" approach, are increasingly being recognized as unsustainable. In response, the concept of the circular economy has emerged as a viable alternative, advocating for practices that prioritize sustainability, resource efficiency, and waste reduction by promoting a closed-loop system where materials are reused, recycled, and regenerated.

Central to the successful implementation of circular economy principles is the integration of digital technologies. Innovations such as the Internet of Things (IoT), blockchain, big data analytics, and artificial intelligence (AI) are revolutionizing how businesses operate, providing new tools and methodologies to enhance sustainability throughout the supply chain and product lifecycle. These digital solutions not only optimize resource management and reduce environmental impact but also empower businesses to innovate and adapt to changing market demands.

This paper aims to explore the role of digital solutions within the frameworks of the circular economy. It will examine how these technologies facilitate more sustainable consumption and production practices, enhance transparency in supply chains, and support the transition toward a circular economic model. By showcasing successful case studies across various industries, the paper will illustrate the transformative potential of digital innovations in achieving circularity. Additionally, it will address the challenges and barriers to implementation, emphasizing the importance of policy support and collaboration among stakeholders.

In summary, the integration of digital solutions into circular economy frameworks represents a critical step toward achieving sustainable development and addressing the myriad environmental challenges facing our planet today. This exploration not only highlights the interconnectedness of technology and sustainability but also underscores the need for ongoing innovation and collaboration in the pursuit of a more resilient and sustainable future.

II. Methods

This paper employs three primary methods to examine the role of digital solutions in circular economy frameworks:

1. **Literature Review**: An extensive literature review was conducted to gather insights from existing research on the intersection of digital technologies and circular economy practices. Academic journals, industry reports, and relevant publications were analyzed to identify key themes, trends, and frameworks that highlight how digital solutions facilitate sustainable consumption and production.
2. **Case Study Analysis**: A selection of case studies from various industries was analyzed to showcase practical applications of digital technologies in promoting circular economy principles. Each case study examined the specific digital solutions implemented, the context in which they were applied, and the outcomes achieved, such as improved resource efficiency and reduced waste.
3. **Qualitative Interviews**: Qualitative interviews were conducted with industry experts and practitioners to gather firsthand insights into the implementation of digital solutions in circular economy practices. These interviews aimed to explore motivations for adopting digital technologies, challenges faced during implementation, and best practices that emerged from successful initiatives.

These methods collectively provide a comprehensive understanding of how digital solutions can enhance circular economy frameworks and contribute to sustainable development.

III. Results

After two rounds of coding, our study identified 13 digital functions from the existing literature that illustrate how digital technologies (DTs) can enhance circular economy (CE) performance, as shown in Table 4. This heatmap visually represents the most frequently discussed codes, with darker shades indicating stronger trends in the reviewed papers. We then classified the 13 digital functions into predefined categories.

From a technological standpoint, the Internet of Things (IoT) was frequently associated with functions like collecting and monitoring. This is because IoT connects wireless sensing devices, enabling effective data gathering and monitoring through internet connectivity. In contrast, big data analytics (BDA) showed an equal distribution of empirical and conceptual codes, while all other codes were weighted toward empirical evidence. Notably, in terms of implementation, artificial intelligence (AI) and general digital technologies exhibited nearly twice as many empirical codes compared to conceptual codes. The AI-related codes predominantly stemmed from papers published after 2020 and were primarily linked to generating insights through data analysis.

The most commonly discussed digital functions for enhancing circular economy practices were collection, monitoring, tracking and tracing, and optimization. Functions such as auto-planning, auto-control, and assessment were heavily grounded in empirical evidence, with auto-control displaying the highest concentration of empirical codes—16 compared to just three conceptual codes. Conversely, the functions of collect, monitor, and forecast had a similar number of empirical and conceptual codes.

Each digital function is discussed in detail below within the relevant categories. AI was predominantly applied in the data analysis category, leveraging its advanced data processing capabilities. BDA is effective in handling and analyzing vast and diverse volumes of data sourced from both the physical environment and human activities, especially at an accelerating pace (Gupta et al., 2019). Furthermore, AI facilitates a faster and more responsive learning process for data analysis based on extensive datasets (Kaplan & Haenlein, 2019; Kristoffersen et al., 2020). General digital technologies are linked with all digital functions due to their ability to integrate various technological capabilities. They showed a somewhat stronger correlation with two specific functions: sharing and auto-control, both of which necessitate the combined support of multiple digital technologies.

The differences between empirical and conceptual codes vary depending on the specific technology in question. For instance, IoT has an almost exclusive emphasis on empirical applications, reflecting its practical utility in real-world scenarios.

The analysis of the role of digital solutions in circular economy (CE) frameworks yielded several significant findings that illustrate the impact of various digital technologies on enhancing sustainability and resource efficiency. Through the literature review and coding process, 13 distinct digital functions were identified as critical in improving CE performance. These functions include collection, monitoring, tracking and tracing, optimization, auto-planning, auto-control, forecasting, data sharing, assessment, predictive maintenance, waste management, material recovery, and product lifecycle management.

The analysis revealed a notable distinction between empirical and conceptual codes associated with different digital functions. Functions such as auto-control, tracking and tracing, and optimization exhibited a significant concentration of empirical codes, indicating their strong grounding in real-world applications and effectiveness in enhancing CE practices. Conversely, functions like collection, monitoring, and forecasting showed a balance between empirical and conceptual codes, suggesting that while these functions are theoretically important, they are also increasingly supported by empirical evidence.

The results highlighted key insights into the technological aspects of digital solutions. IoT was consistently linked to data collection and monitoring functions, showcasing its critical role in enabling real-time tracking and improved decision-making. Artificial intelligence (AI) and big data analytics (BDA) were predominantly associated with data analysis functions, as their advanced capabilities allowed for handling vast datasets, leading to more informed insights and faster decision-making processes. General digital technologies displayed strong interlinkages with multiple functions, particularly in areas requiring integration across different systems, such as sharing and auto-control.

Several case studies were analyzed to illustrate the practical applications of these digital functions in various sectors. These case studies demonstrated how companies successfully implemented digital solutions to enhance their circular economy practices, achieving significant improvements in resource efficiency, waste reduction, and overall sustainability. The findings indicate that the integration of digital technologies within circular economy frameworks not only facilitates better resource management but also fosters innovation and collaboration among stakeholders, ultimately contributing to a more sustainable future.

IV. Discussion

The findings from our study illuminate the integral role that digital technologies (DTs) play in advancing the circular economy (CE) by enhancing energy and resource efficiency across the product lifecycle. The identification of reduction mechanisms as a central theme in the literature underscores the practicality and relevance of adopting digital solutions to achieve sustainable consumption and production.

Role of Digital Technologies

One of the most significant outcomes of this research is the emphasis on improving production and energy efficiency as a primary benefit of Industry 4.0. Enhanced process efficiency directly correlates with reduced waste in both materials and energy consumption. The digital functions identified—such as monitoring, optimization, and auto-control—are crucial in this regard. These functions allow for real-time adjustments and proactive management of resources, which are essential for minimizing waste generation.

The emphasis on logistics optimization further highlights how DTs can lead to sustainable practices. By collecting and sharing data regarding transportation logistics, companies can optimize routes and reduce fossil fuel consumption. This is particularly relevant in today's context, where supply chain efficiency is increasingly scrutinized in light of environmental impacts. The ability to leverage real-time data not only optimizes operations but also contributes to a significant reduction in the carbon footprint associated with transportation.

Short-Term vs. Long-Term Benefits

The study also distinguishes between short-term and long-term benefits of digital technologies in CE practices. In the short term, real-time monitoring facilitates quick and responsive equipment management, which is crucial for enhancing energy efficiency. Self-controlling robotics and automated systems can lead to immediate improvements in production processes by minimizing human errors, thus enhancing operational reliability.

In the medium to long term, the implementation of tracking and tracing technologies offers deeper insights into process efficiencies. This can result in more accurate analysis and planning, ultimately reducing waste from operational errors. The ability to analyze trends over time allows organizations to make informed decisions that lead to sustainable practices and resource conservation.

End-of-Life Efficiency

The end-of-life stage of products is another area where digital technologies show substantial promise. The integration of AI and control technologies into disassembly processes can enhance efficiency significantly. AI-driven insights enable better decision-making regarding disassembly levels and sorting waste materials, which are critical for effective recycling efforts. The capacity for automatic sorting not only increases recycling rates but also minimizes labor costs, illustrating a clear economic advantage alongside the environmental benefits.

Moreover, the ability of AI to facilitate connections between waste generators and collectors enhances waste recovery efficiency. This interconnectivity is essential in closing the loop of the circular economy, ensuring that materials are recovered and reused rather than discarded.

Challenges and Considerations

Despite the numerous benefits associated with integrating digital solutions into CE frameworks, challenges remain. The reliance on advanced technologies raises concerns about data privacy, security, and the need for robust infrastructure to support these digital solutions. Additionally, organizations must navigate the complexities of integrating new technologies into existing systems and processes, which can be resource-intensive and require substantial investment.

Furthermore, the varying levels of technological readiness across different industries and regions can create disparities in the adoption of these solutions. To address these challenges, it is crucial for stakeholders—including policymakers, businesses, and academic institutions—to foster an environment that supports innovation and collaboration. Creating regulations that encourage data sharing while ensuring privacy and security will be essential in driving the widespread adoption of digital technologies in circular economy practices.

In summary, our study reinforces the notion that digital technologies are pivotal in enhancing resource efficiency and sustainability within the circular economy. By improving energy efficiency and reducing waste throughout the product lifecycle, these technologies not only contribute to environmental goals but also provide economic advantages. However, to fully realize the potential of digital solutions in CE frameworks, stakeholders must address the associated challenges, ensuring a collaborative and supportive environment for innovation and technology adoption. Ultimately, the integration of digital solutions into circular economy practices can drive meaningful change toward a more sustainable future.

[3] Ingush State University
Econ-help@mail.ru

Abstract

This paper delves into the critical role that tax regulation plays in advancing the transition to a green economy by embedding sustainable development goals within fiscal policy frameworks. The research investigates various fiscal instruments, such as carbon taxes, environmental levies, tax incentives for renewable energy, and subsidies aimed at promoting eco-friendly technologies. These tools are examined in terms of their effectiveness in encouraging businesses and individuals to adopt sustainable practices, reduce carbon emissions, and decrease overall environmental degradation. The paper also highlights the challenges that arise when governments attempt to balance economic growth with the need to reduce environmental impact. It addresses the difficulties in aligning fiscal policies with both short-term economic objectives and long-term sustainability goals. Moreover, the study emphasizes the importance of international collaboration in ensuring that green tax regulations are coherent across borders and support global efforts to combat climate change. Through an analysis of successful case studies and emerging trends in green fiscal policy, the paper offers recommendations for improving tax systems to better facilitate the shift toward a low-carbon, resource-efficient economy. These include the need for more robust tax incentives for renewable energy investments, the gradual phasing out of environmentally harmful subsidies, and the implementation of tax schemes that can simultaneously stimulate green innovation and economic resilience.

Keywords: green economy, sustainable development, carbon tax, environmental subsidies, renewable energy incentives, eco-friendly practices

I. Introduction

The global transition to a green economy has emerged as one of the most pressing challenges of the 21st century, as nations seek to balance economic growth with environmental sustainability (fig.1). Climate change, resource depletion, and environmental degradation have underscored the urgent need for a shift toward more sustainable modes of production and consumption. Central to this transition is the role of fiscal policy, particularly tax regulation, which has the potential to influence economic behaviors, promote eco-friendly practices, and reduce the environmental impact of industries.

Tax policies designed to incentivize sustainable development can be powerful tools for driving the green economy. By incorporating environmental objectives into fiscal frameworks, governments can encourage businesses to reduce carbon emissions, invest in renewable energy, and adopt cleaner technologies. Instruments such as carbon taxes, tax breaks for renewable energy investments, and subsidies for green innovation not only promote environmental goals but also create opportunities for economic growth in emerging sectors.

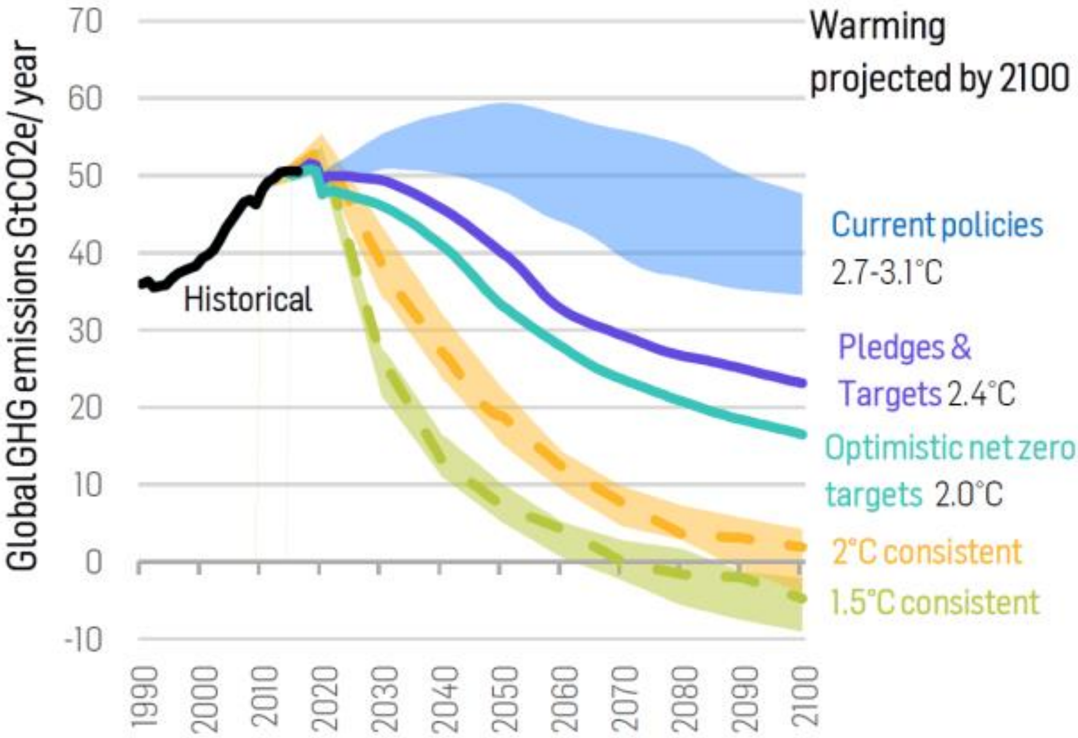

Figure 1: *Emissions and expected warming based on pledges and current policies*

The uncertainty surrounding future regulatory changes and the risks associated with climate change pose significant challenges for investors. These challenges can be broadly categorized into two main risk groups.

First, there are physical climate risks that directly affect the financial system. As climate change leads to more frequent and severe natural disasters, the realization of these physical risks can result in substantial financial losses. For instance, extreme weather events can damage assets, disrupt supply chains, and lead to increased insurance claims, impacting the financial sector directly.

Second, transition risks refer to potential financial losses or economic disruptions linked to the shift towards a low-carbon economy and the corresponding tightening of policies. These risks may affect the financial sector indirectly, manifesting through fluctuations in asset and collateral values or rising operational costs. Transition risks can arise from changes in consumer preferences, technological advancements, or stricter regulatory requirements aimed at reducing carbon emissions.

It's important to note that physical risks and transition risks can interact with each other. For example, failing to implement effective policies for transitioning to a low-carbon economy could exacerbate physical risks over time, as the effects of climate change intensify. Conversely, aggressive regulatory measures that accelerate the transition may incur short-term economic costs but could ultimately decrease the likelihood of experiencing severe physical risks in the future. This interplay underscores the complexity of climate-related risks and the need for investors to consider both types of risks in their decision-making processes.

However, implementing green tax regulations poses significant challenges. Governments must strike a delicate balance between fostering economic growth and addressing environmental concerns. In addition, tax systems need to be designed in a way that ensures fairness and does not disproportionately burden certain sectors or populations. The complexity of integrating sustainable development into fiscal policy also requires international coordination, as inconsistent policies across borders can undermine global efforts to mitigate climate change.

This paper explores the intersection of tax regulation and the green economy, examining how sustainable development can be integrated into fiscal policies to support a low-carbon, resource-efficient future. It analyzes the effectiveness of various green fiscal measures, the obstacles to their implementation, and the potential for international cooperation in achieving a sustainable economic transformation. By addressing these issues, the study aims to provide insights into how tax regulation can be leveraged to accelerate the transition to a greener economy.

II. Methods

This study utilizes three specific methods to analyze the integration of sustainable development into tax regulation and its role in transitioning to a green economy:

1. Comparative Policy Analysis:

The study compares the tax policies of three countries that have implemented significant green fiscal measures: Sweden, Germany, and South Korea. By analyzing the structure, implementation, and outcomes of their carbon tax systems, renewable energy tax incentives, and environmental subsidies, the study identifies effective strategies and challenges associated with these policies. This comparative approach helps to highlight best practices and lessons learned from diverse economic and regulatory environments.

2. Case Study of Carbon Tax in Sweden:

A detailed case study of Sweden's carbon tax policy was conducted to examine how a well-designed tax regulation can drive substantial reductions in greenhouse gas emissions. The study investigates the policy's design, including tax rates, coverage across sectors, and mechanisms for revenue recycling. The economic and environmental outcomes of the policy, such as its impact on emissions reduction and renewable energy adoption, are also evaluated using available data from government reports and environmental agencies.

3. Expert Interviews:

Structured interviews were conducted with tax policy experts, environmental economists, and government officials involved in the design and implementation of green tax regulations. The interviews focused on practical challenges in implementing green fiscal policies, the political and economic trade-offs, and future opportunities for integrating sustainability into national and international tax frameworks. These expert insights provide a deeper understanding of the real-world complexities of transitioning to a green economy through fiscal policy.

III. Results

In the era of transformative economics, the global shift toward green, low-carbon, and circular development is rapidly gaining momentum, establishing itself as a key trajectory for future economic growth. This paradigm shift not only reshapes environmental management strategies but also catalyzes the evolution of green tax systems. Green taxation, which targets polluters, aims to internalize external environmental costs, correct inefficiencies in market resource allocation, and enhance overall economic efficiency.

Despite the acknowledged importance of green taxation, theoretical research on its potential adverse effects on regional green development and innovation remains limited. Existing studies primarily concentrate on its macroeconomic impact and environmental benefits, leaving gaps in understanding the specific mechanisms through which green taxation influences regional innovation, particularly in terms of corporate resource allocation and the crowding out of limited financial and material assets.

This gap in theoretical research hampers a comprehensive evaluation of green taxation, affecting the efficiency and design of related policies. According to the Resource-Based View (RBV), the reallocation of resources toward green initiatives may reduce a firm’s ability to innovate and compete in non-green sectors. Furthermore, the innovation system perspective suggests that while green taxation can incentivize green technological advancements, it may divert resources from other innovation areas, thereby diminishing overall innovation capacity. The technological lock-in theory further posits that once certain technologies are adopted, economies of scale and learning effects make it difficult for systems to pivot away from established paths.

This study investigates the potentially negative effects of green taxation on regional green development and innovation. By analyzing how green taxation influences corporate behavior related to green innovation, the research introduces the novel idea that such taxes may inadvertently weaken a region's broader innovation capabilities. Through a unique heterogeneity analysis, the study examines the impact of green taxation on regions with varying innovation capacities, exploring how resource imbalances may lead to declines in overall innovation potential. This approach fills a critical theoretical void in the current literature and provides practical insights for policymakers aiming to refine green taxation to support high-quality green economic development.

Impact on Green Development and Green Innovation:

Green taxation, as a strategic policy instrument, plays a crucial role in advancing sustainable practices. By providing tax reductions on environmental equipment and eco-friendly technologies, green taxation incentivizes businesses to invest in and adopt clean and resource-efficient technologies. This approach helps lower resource consumption and environmental pollution, leading to significant improvements in regional green development. Moreover, green tax policies encourage companies to implement energy-saving and emission-reduction measures, which not only improve energy efficiency but also reduce emissions during the production process, ultimately enhancing productivity.

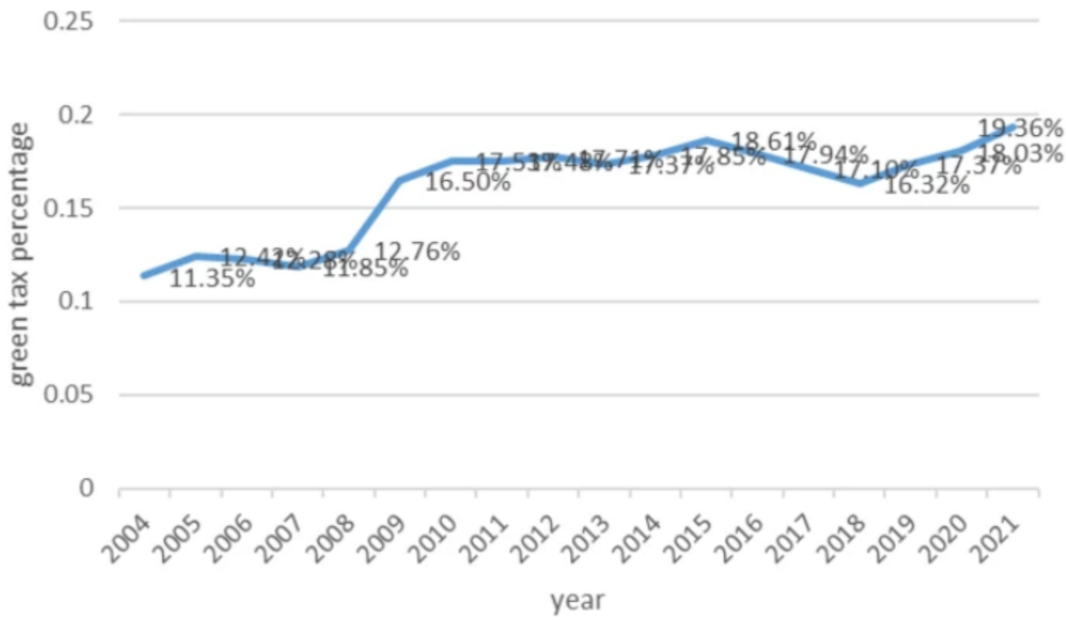

Figure 2: *National green tax intensity over time*

Broad green taxes, in contrast, take a more holistic approach by considering the synergistic development of ecological and economic systems. These taxes aim to regulate not only post-event outcomes but also provide preemptive guidance and control, as highlighted by the OECD (2010). Broad green taxes encompass a variety of fiscal measures, including environmental protection taxes, pollution fees, and specific environmental provisions found within various tax categories.

Due to difficulties in obtaining data related to tax incentives for environmental protection and energy conservation in value-added tax and corporate income tax, this study adopts a composite measure for broad green taxes. Specifically, broad green taxation is defined as the ratio of the total amount from environmental protection tax, domestic consumption tax, resource tax, urban maintenance and construction tax, farmland occupation tax, and vehicle and vessel tax to the total regional tax revenue.

This methodology enables a nuanced and comprehensive assessment of both narrow and broad green tax policies and their impact on regional green development and innovation capacity. The findings of this analysis are visually represented in Fig. 2, which illustrates a timeline of national green tax intensity, showcasing the evolution and implementation of these policies over time.

At the same time, imposing higher taxes on polluting activities pushes businesses to increase investments in environmental research and development (R&D). This shift drives innovation in green technologies and accelerates the transformation of traditional industries toward more sustainable practices. As a result, green taxation plays a key role in fostering the development and growth of green industries.

However, the positive effects of green taxation on innovation and development are not immediate. The adoption and implementation of new green technologies often take time, and there may be a delay in seeing the full impact of such innovations on regional green growth. Additionally, the introduction of green taxes can raise operational costs for businesses in the short term, which could slow down their ability to innovate and implement sustainable practices.

Given these dynamics, the following hypotheses are proposed:

- Hypothesis 1: Green taxation positively impacts regional green development by reducing resource consumption and pollution while improving energy efficiency.
- Hypothesis 2: Green taxation promotes green innovation by encouraging enterprises to invest in environmental R&D and adopt cleaner technologies.
- Hypothesis 3: The positive impact of green taxation on regional green development and innovation may exhibit a lagging effect due to the time required for technology adoption and the potential increase in operational costs.

IV. Discussion

The introduction of green tax policies, while increasing business costs, simultaneously incentivizes firms to invest in green technologies due to the tax benefits and reductions offered. This shift, however, may result in a reallocation of limited corporate resources, potentially reducing investment in research and development (R&D) and innovation in other critical areas. According to the Resource-Based View (RBV), a firm’s competitive advantage and innovation capacity stem from its unique resources and capabilities. Green taxation directs firms to focus their finite resources on green technologies in pursuit of tax incentives, which might undermine R&D efforts in non-green sectors, affecting their competitiveness and overall innovative potential.

Innovation system theory underscores that innovation is a collective process involving multiple stakeholders, such as enterprises, governments, and research institutions. Through interactions among these actors, new knowledge is generated and applied. Green taxation, by reshaping resource allocation and incentives, can enhance innovation in green technologies but may inadvertently divert resources from other areas of innovation (fig.3). This shift could dampen the region's overall innovation capacity, as resources become concentrated on green initiatives at the expense of broader technological progress.

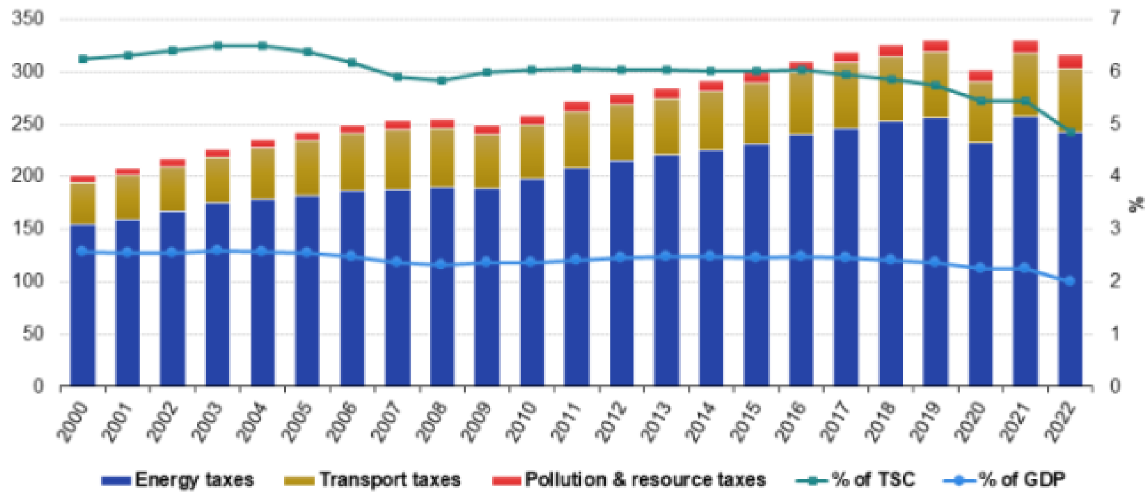

Figure 3: *Environmental tax revenue by type and total environmental taxes as share of TSC (total government revenue from taxes and social contributions) and GDP, EU, 2002-2022 (€ billion, %)*

Additionally, technological lock-in and path dependency theories suggest that once a specific technological trajectory is adopted, systems tend to become entrenched in that path due to factors like economies of scale, synergistic effects, and learning advantages. As a result, green taxation might lead businesses and regions to become overly reliant on established green technologies, limiting exploration of alternative or disruptive innovations. This dependence could hinder long-term innovation growth and adaptability to new technological paradigms.

In light of these dynamics, the following hypotheses are proposed:

- Hypothesis H3: Green taxation exerts an inhibitory influence on regional comprehensive innovation capacity, as it diverts resources from broader R&D efforts to green technology investments.

- Hypothesis H4: While advancing regional green development and reallocating corporate resources towards green technologies, green taxation impedes the enhancement of regional innovation capacity by limiting investment in non-green sectors and fostering technological lock-in.

Measurement of Green Taxation:

In this study, green taxation is categorized into two distinct types: narrow green taxes and broad green taxes.

1. Narrow Green Taxes: These taxes specifically target pollutant emissions and are designed to promote environmental protection and sustainable development. Narrow green taxes, such as environmental protection taxes, mark the shift from pollution fees to a formal taxation structure. Prior to the introduction of environmental protection taxes, pollution fees were used as a temporary solution.

2. Broad Green Taxes: These taxes encompass a more holistic approach, focusing on the integrated development of ecological and economic systems. Broad green taxes cover both post-event regulatory actions and proactive guidance for environmental management (OECD, 2010). This category includes a wide range of fiscal measures, such as environmental protection taxes, pollution fees, and specific environmental provisions within tax categories like value-added tax and corporate income tax.

Given the challenge of obtaining detailed data on tax incentives for environmental protection within broader tax categories, this study employs a composite measure for broad green taxation. Broad green taxation is defined as the proportion of total environmental protection tax, domestic consumption tax, resource tax, urban maintenance and construction tax, farmland occupation tax, and vehicle and vessel tax relative to total regional tax revenue. This composite measure allows for a comprehensive evaluation of both narrow and broad green tax policies' effects on regional green development and innovation capacity.

Most existing research primarily focuses on the economic effects of green taxation on enterprises, with comparatively less attention given to its implications for innovation capacity. The findings of this study align with prior research, indicating that green taxation can serve as a catalyst for green development and innovation. However, both narrow and broad green taxation have been shown to negatively impact the overall innovation capacity of enterprises. This result contrasts with some literature that suggests a positive influence on innovation, implying that green taxation may initially impose a burden on corporate innovation due to resource redistribution and resulting imbalances. The long-term effects of this taxation warrant further investigation.

Additionally, this research reveals significant regional disparities in the impact of green taxation on green development and innovation—an aspect that has not been sufficiently addressed in previous studies. Specifically, the study demonstrates a positive effect in Eastern regions, while the impact is either negligible or negative in Central and Western regions. This variation can be linked to differences in regional economic development, industrial structures, and innovation capacities, underscoring the necessity for region-specific green tax policies.

A key contribution of this study is the identification of a nonlinear relationship between green taxation and both green innovation and development. This insight challenges the linear assumptions present in some existing literature, suggesting that the effects of green taxation may vary with different tax levels. Future research should explore the optimal tax level that balances the promotion of green innovation against the potential negative impacts on corporate innovation capacity.

Ultimately, the study enhances traditional heterogeneity analysis by examining regions with varying innovation capabilities. The results emphasize the differing effects of green taxation across areas with different levels of corporate innovation. In regions with high corporate innovation capacity, narrow green taxation shows a delayed effect in fostering green development, potentially because enterprises need time to adjust their innovation strategies to new tax policies. Conversely, in regions with lower innovation capacities, narrow green taxation encourages a quicker adoption of green practices, suggesting that modest incentives may be sufficient to spur action among businesses in these areas.

This differentiation in impact highlights the importance of regional innovation capacities in policy-making. Identical policies may require tailored approaches across different regions. Notably, broad green taxation has not demonstrated significant positive effects on green development and innovation in either region type, indicating the need for a more nuanced approach in designing green taxation to effectively promote green innovation and sustainable development.

THE ROLE OF FORESTS IN THE CARBON CYCLE: MECHANISMS OF CARBON ABSORPTION AND STORAGE

Elita Yaumieva[1], Aishat Baysangurova[2], Islam Gumaev[3]

Abstract

Forests play a key role in the carbon cycle, acting as major carbon sinks and important carbon stores on Earth. This article examines how forest ecosystems perform photosynthesis, the process by which they capture carbon from the atmosphere and convert it into organic matter. Particular attention is paid to the various mechanisms of carbon assimilation, such as the transformation of carbon into biomass, roots and soil, as well as its long-term storage. One of the main factors influencing the efficiency of carbon absorption is the forest type. For example, tropical forests, due to their high biomass and species diversity, absorb significantly more carbon compared to temperate and boreal forests. The influence of climatic conditions, such as temperature and rainfall, on the process of photosynthesis and tree growth is also considered. Forest age also plays an important role: young forests accumulate carbon faster, while old forests can reach a state where carbon accumulation slows down. The article also highlights the importance of preserving and restoring forest ecosystems as a strategic approach to combating climate change. Increasing forest area and implementing sustainable forest management practices can significantly increase their capacity to absorb carbon, as well as improve other ecosystem services such as maintaining biodiversity and protecting soil from erosion. Importantly, forest destruction caused by logging and land tenure change releases significant amounts of carbon into the atmosphere, exacerbating the problem of climate change.

Keywords: forests, carbon cycle, carbon sequestration, carbon storage, climate change, ecosystem services, photosynthesis, sustainable forest management, forest restoration

I. Introduction

Despite the growing trend towards fragmentation of the global economy, the loss of influence of various international organizations and the weakening of previously concluded agreements, the idea of preventing catastrophic climate change, first enshrined in the UN Framework Convention on Climate Change (UNFCCC) in 1992, continues to be relevant and receives support from all countries of the world. Russia, although reducing its participation in various interstate initiatives in recent years, nevertheless emphasizes its commitment to decarbonization of the economy. The Low Carbon Development Strategy (LCDS) [1], adopted in October 2021, sets the goal of achieving carbon neutrality of the national economy by 2060. In accordance with this strategy, the transition to carbon neutrality is planned to begin only after 2030 (Fig. 1). An important role in this process is given not to measures in the energy sector, which might be expected, but to a more than twofold increase in carbon absorption by the country's forests in the area of land use, land-use change and forestry (LULUCF). This strategy, according to a number of forestry experts [2, 3], is based on rather unreliable foundations and is therefore considered risky.

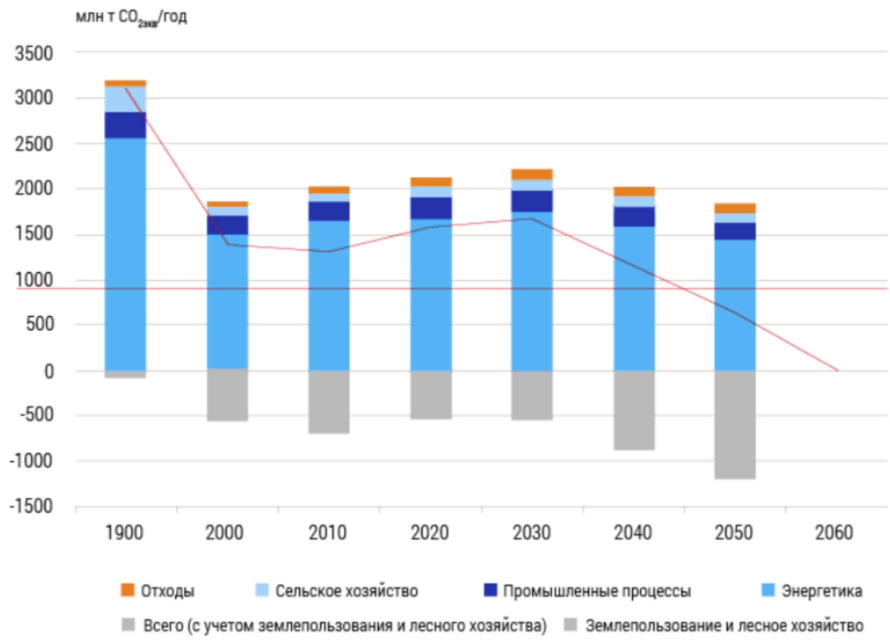

Figure 1: *Target scenario of the Low Carbon Development Strategy*

II. Methods

Low Carbon Development Strategy (LCDS) and its presentation at the UNFCCC Conference of the Parties in Glasgow in 2021 generated a great deal of interest and a number of publications devoted to various aspects of decarbonization of the Russian economy [4–11]. This work aims to assess the feasibility of achieving this goal, taking into account global historical experience, and to identify possible ways to solve this problem.

Over the past thirty years, two main periods have been distinguished in the dynamics of greenhouse gas (GHG) emissions in Russia: a sharp decline in the 1990s and a gradual increase in 2000–2020 (Fig. 1). The minimum net emission (taking into account the absorption of carbon dioxide by biota) was recorded in 2010, which is associated with an increase in the absorption capacity of forests due to a reduction in the volume of timber harvesting and the overgrowing of abandoned agricultural lands.

While the drop in emissions in 1990–2000 affected virtually all sectors of the national economy and affected emissions of all greenhouse gases (including carbon dioxide, methane, nitrous oxide, chlorofluorocarbons , and others), the subsequent partial recovery in emission volumes occurred primarily in the energy sector and, to a lesser extent, in industrial processes, where carbon dioxide emissions also increased (Fig. 1). A significant risk to Russia's long-term economic interests is the misconception that increasing the role of forests and properly accounting for this role can solve the practical tasks of the Paris Agreement and the Low Carbon Development Strategy (LCDS) to reduce greenhouse gas emissions without systematic actions to green the economy as a whole, especially in the energy sector. The temptation to rely on such a solution to the problem is great and is due to obvious geographic factors. According to the World Bank, about 20% of the world's forest cover is in Russia. These forests have the potential to become one of the key environmental donors in terms of greenhouse gas absorption and play a leading role in the formation of the carbon balance. Therefore, from the point of view of carbon regulation at the national level within the framework of the Paris Agreement and the goals outlined in the LULUCF [1], it is extremely important to correctly assess the net sink of the land-use change and forestry (LULUCF) sector in Russia and its dynamics in the coming decades. It should be emphasized that estimates of the current carbon balance in Russian forests and its dynamics in the coming decades vary significantly [2–3, 8-11]. Differences in estimates of even the current net flow, conducted by various institutions, can reach fourfold. There are diametrically opposed opinions on further changes in the net sink: from its dramatic reduction by more than five times [3] to a twofold increase by the middle of the century, which is directly reflected in the LULUCF concept [1]. For example, recent research by the World Resources Institute shows that between 2001 and 2019, net carbon sinks in Russia's forests averaged 1.79 billion tonnes of CO_2- eq per year, equivalent to 24% of the world's total forest sinks. These results are also consistent with Boston estimates. Consulting Group (BCG) [15], which record annual absorption by Russian forests in the range of 1.8 to 2.2 billion tons of CO_2- eq ., as well as data from Global Forest Watch , indicating similar removal values of 1.74 billion tonnes of CO_2- eq over the period 2001–2021.

From the point of view of Russia's official reporting under the United Nations Framework Convention on Climate Change (UNFCCC), according to the National Inventory Report of Anthropogenic Emissions by Sources and Removals by Sinks of GHGs [12], in 2021 the greenhouse gas balance in the land-use change and forestry (LULUCF) sector updated the minimum since 2000 and amounted to 484.8 million tons of CO_2-eq . per year, which is equivalent to a 13% decrease in net sink compared to previous estimates submitted to the UNFCCC. It is necessary to note not just an unprecedented decrease in absorption for lands classified as hayfields and pastures, for which the average absorption over a five-year period (2016–2020) was 44.5 million tons of CO_2- eq . per year, but a complete absence of runoff for this land category in 2021 and a total emission of 3.8 million tons of CO_2- eq . For forest lands, there is also a decrease in net runoff, but less significant on a category scale - by 3.8% compared to 2020, namely by 23.5 million tonnes of CO_2- eq , which may be associated with record forest fires in 2021 (Figure 2).

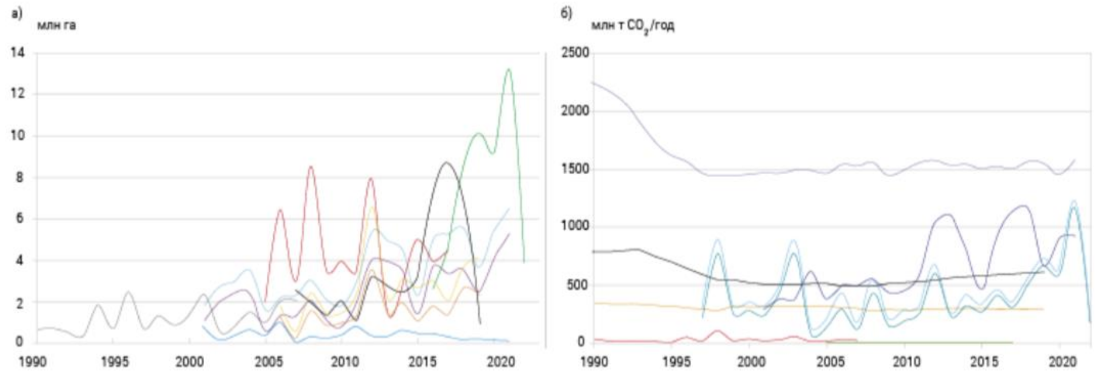

Figure 2: *Forest areas burned and forest loss from fires (a) and carbon dioxide emissions from forest loss compared to emissions from fuel combustion (b) in Russia*

The traditional methodology for assessing national anthropogenic greenhouse gas removals in the land-use change and forestry (LULUCF) sector is the guidelines for national greenhouse gas inventories developed by the Intergovernmental Panel on Climate Change (IPCC) [2] and their supplements [3]. The list of carbon pools and land-use categories remains classical and, without undergoing significant changes, is used by all researchers to assess the carbon budget.

Methods for estimating both removals and emissions of CO_2 equivalent are based on two main approaches. The first, the biomass gain and loss method, involves determining the annual change in carbon stock as the difference between annual carbon gains and losses in tonnes, and is a function of carbon changes and losses. The second approach, the stock difference method, is considered preferable due to its high accuracy and reliability, as it is characterized by the difference in carbon stocks in reservoirs at two specific points in time. However, regardless of the approach chosen, one of the main difficulties remains the identification of the age, stock, and species composition of forest areas, which are used as the main sources of data for the calculations.

In Russia, the official methodology approved by the Ministry of Natural Resources is the methodology of regional assessment of forest carbon budget (ROBUL), developed by the Institute of Global Climate and Ecology (IGCE) named after Academician Yu. A. Izrael and the Center for Forest Ecology and Productivity (CEPL) of the Russian Academy of Sciences (RAS) [5]. This methodology was verified within the framework of the UNFCCC and is intended to provide a unified approach to assessing the carbon budget in Russian forests.

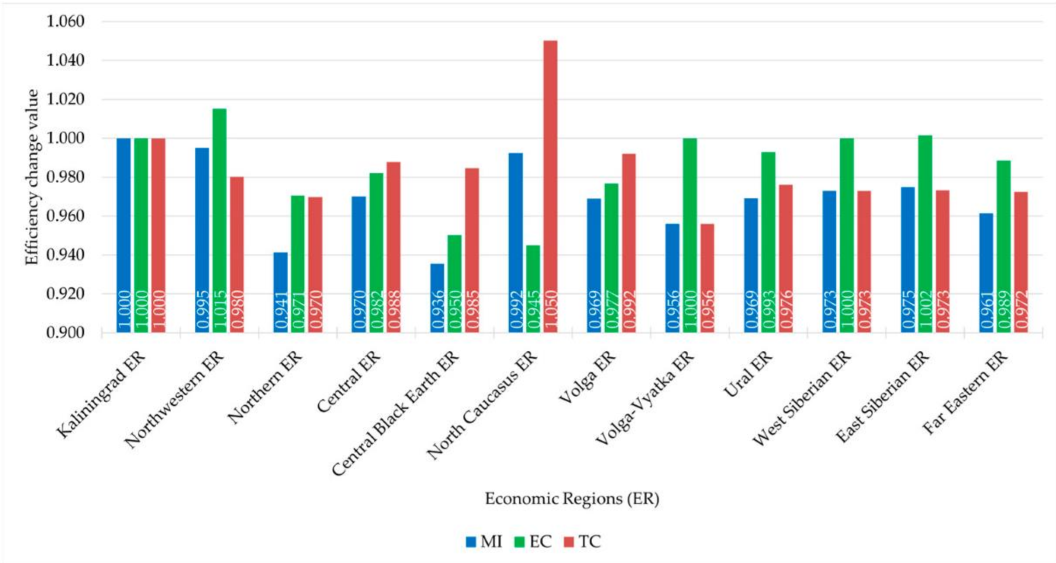

Figure 3: *Average total factor productivity and efficiency changes of forest carbon sinks among economic regions in Russia from 2009 to 2021.*

Further decomposition of the technical efficiency change values is presented in Fig. 3. As mentioned before, three regions, namely Kaliningrad, Volga-Vyatka, and West Siberian ERs, did not perform any efficiency improvements, therefore their PTE and SE values remained unchanged. Along with them, six DMUs (namely Central, Central Black Earth, North Caucasus, Ural, and Far Eastern ERs) kept their management regimes (PTEs) unmodified. During the study period, related improvements occurred in Northwestern ER (1.4%) and East Siberian ER (0.1%), while Northern and Volga ERs deteriorated by 3.5% and 2.3%, respectively. Therefore, these changes made a significant contribution to their performance. As stated before, deterioration in terms of scale efficiency is the main factor hindering the productivity of forest carbon sinks in Russia. In particular, the related value sufficiently decreased in the predominantly agricultural regions of Central Black Earth and North Caucasus ERs, accounting for 5% and 5.5%, respectively. Meanwhile, Central, Volga, Ural, and Far Eastern ERs decreased only by 1.8%, 0.1%, 0.7%, and 1.1%, respectively. Noteworthy, the scale efficiency increment in forest carbon sinks occurred in the Russian North, namely in Northwestern (0.2%) and Northern (0.5%) ERs. As stated in the report [7] by the Russian Federal Service for Hydrometeorology and Environmental Monitoring (Roshydromet), high warming rates occurred in these territories, presumably contributing to local forests absorbing more carbon.

III. Results

Our estimates show a large, long-term persistent sink of 3.56 ± 0.37 Pg C yr−1 in global forests since at least 1990, with a statistically insignificant change, based on Monte Carlo simulations and Cohen's d (Supplementary Fig. 1). Although stable overall, the contribution to this carbon sink of different forest biomes has fluctuated greatly over time. In the tropics there has been a shift from equal contributions of intact and regrowth tropical forests in the 1990s to 65% of the sink being in regrowth forests in the 2010s, as the intact sink declined and the regrowth sink increased (Table 1). Boreal and temperate forests contributed similar carbon sinks in the 1990s, but by the 2010s the boreal sink had decreased to less than half of the temperate sink (Table 1). Carbon stock densities (Mg C ha−1) in all forest biomes in all climate zones steadily increased (Extended Data Fig. 2c), indicating that forest ecosystems across the planet continuously sequestered carbon, implying that a universal growth factor, or several factors, was enhancing forest sinks on continental scales. A suite of multidisciplinary evidence indicates that the global carbon-sink persistence and carbon-density increases were in part the result of CO2 fertilization contributing to substantially increased photosynthesis17,18, as well as to longer growing seasons in temperate and boreal regions26. These factors may have outweighed the negative effects on forest carbon from global heating, changing rainfall patterns and changes in the frequency and severity of natural disturbances in the remaining forests.

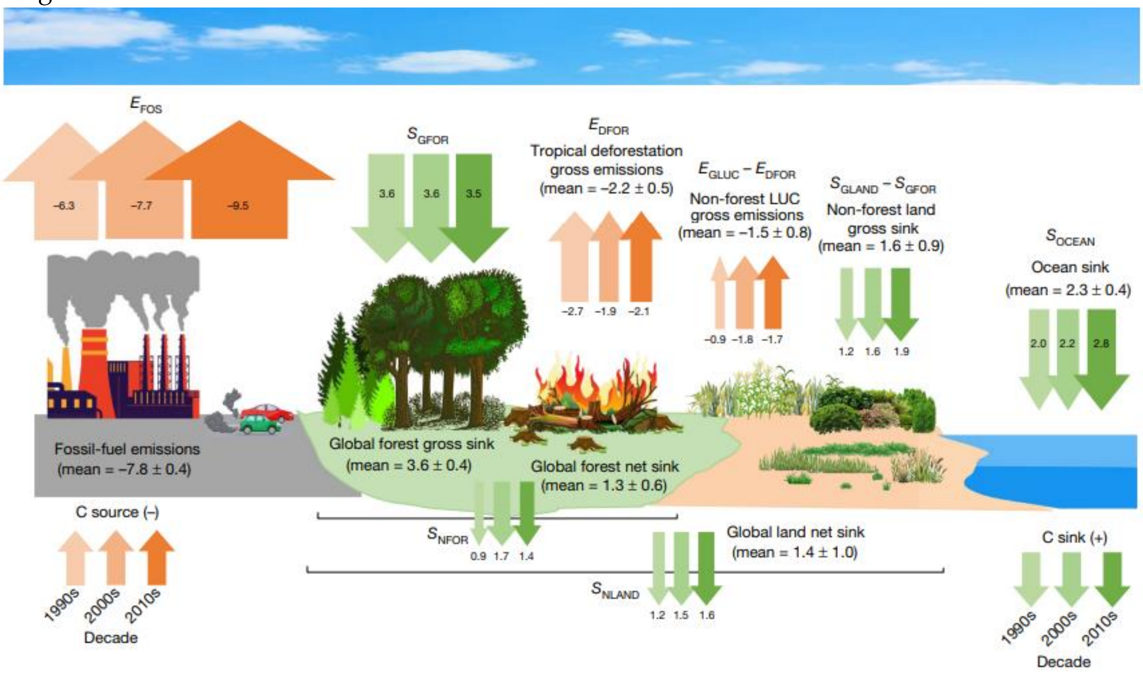

Figure 3: *Integration of inventory-based global forest carbon fluxes with the GCB*

The carbon pool of the world's forests is exposed to risks from deforestation, degradation, and disturbance caused or exacerbated by climate change. In intact tropical forests, the main threats are ongoing deforestation and degradation, which are the main drivers of reduced carbon sequestration (Extended Data, Figure 1). Increasing frequency and severity of droughts have also killed millions of trees, weakening the carbon pool in the Amazon. Given that the combined pool in intact and recovering forests remains stable, the net carbon sequestration for tropical forests as a whole is largely determined by the level of emissions from deforestation. Reducing deforestation and degradation is the only way to keep the carbon stored in forests from escaping into the atmosphere. Protecting tropical forests also helps to maintain their biodiversity and their capacity to sequester carbon into the future.

Boreal forests have been significantly impacted by climate change, including greater temperature increases and variations than other regions. Climate change has disrupted carbon cycling in vegetation and soils, and has increased the impacts of wildfires, pest outbreaks, and droughts. The high levels of carbon storage and sequestration in boreal forest necromass threaten to increase decomposition rates and wildfires during drought conditions. These impacts have made Canadian forests a carbon source, while forests in Asian Russia have lost 42% of their carbon sequestration capacity over three decades, particularly in the late 2010s. Future threats to boreal forest carbon dynamics also include northward shifts in bioclimatic zones, leading to permafrost thawing and megafires such as those that occurred in 2020–2022, as well as increased risks of major pest outbreaks and increased legal and illegal logging, which in turn releases methane and CO_2 .

Temperate forests include the most intensively managed forest ecosystems on Earth. Increased carbon sequestration in these forests is mainly due to past tree planting in China. Temperate forests regenerated on abandoned agricultural land or heavily logged forests in the first half of the 20th century are now approaching an age where their growth rates begin to decline, although growth trajectories and successional dynamics vary within the temperate forest biome. Climate change has increased the frequency and intensity of natural disturbances, which in turn has caused more severe bark beetle outbreaks after droughts in some European forests. In addition, increased deforestation in the temperate zone over the past three decades (+17%) has reduced carbon stocks.

IV. Discussion

To assess the possibilities of achieving carbon neutrality, a comparative analysis of the processes taking place in the economy, especially in the energy sector, in a number of countries was conducted. Both the leaders of decarbonization (the European Union, Japan, the United States and Canada) and the largest developing economies that are just beginning their path to the declared carbon neutrality (China, India, Turkey) are included.

In the energy sector, for the leading countries representing industrially developed economies, there is a transition to stabilization of specific (per capita) energy consumption with its moderate reduction. While in developing economies, including Russia, this indicator continues to grow.

When analyzing the carbon intensity of energy consumption, no significant division is observed. In most countries (EU, USA, Japan, China, Turkey) the trend towards decreasing specific emissions in the energy sector has been maintained over the past 50 years (with the exception of a three-year period in Japan, when there was a mass closure of nuclear power plants after the Fukushima accident in 2011). In Canada, this indicator stabilized back in 1985 at an unprecedentedly low level due to the widespread use of hydro and nuclear energy. In Russia, this indicator has stagnated since 2008, remaining slightly below the world average, while India's energy sector has demonstrated surprising constancy over the entire 50-year period due to the predominance of coal in the national energy balance.

The events of the last year have radically changed all previously existing forecasts of economic development, both for Russia and for many other countries. In this regard, for our study, which sets the task of risky extrapolation of the intensity of policy to curb greenhouse gas emissions for several decades ahead, the method of historical extrapolation was chosen instead of the traditional approach based on detailed assumptions about economic development. We are confident that historical extrapolation can yield useful results, which is confirmed by our experience in creating long-term forecasts for the development of global energy. For example, forecasts compiled in 1990 showed a coincidence with actual data on energy consumption in the world within 2% over a horizon of more than 30 years. However, taking into account the unusually high dependence of the final result on political decisions, we decided to consider two extreme scenarios of Russia's movement towards climate neutrality: an optimistic one and a real one, which takes into account, among other things, current turbulent events. The UN median scenario was chosen as the demographic scenario in both options, which assumes a gradual decrease in the country's population to 128 million by 2060.

The optimistic scenario is based on the assumption that ideas about the fight to preserve the climate will gain much greater influence in Russian society, comparable to that observed in developed countries over the past three decades. In this case, Russia will be able to count on decarbonization rates that correspond to the best world standards (see Table 2). In general, the parameters of the optimistic decarbonization scenario are as follows:

- The rate of reduction of specific (per capita) anthropogenic greenhouse gas emissions is 1% per year, which corresponds to the average value for developed countries in the period from 1990 to 2020.

- Forest management indicators follow the Strategy-2030 (2021) and assume full restoration of forests after all clear-cutting; the dynamics of carbon absorption by forests corresponds to high national estimates, which, it should be noted, significantly diverge from international recommendations.

- Additional carbon fixation by forests is taken into account, taking into account changes in climatic factors (temperature and precipitation), as well as the fertilization effect resulting from an increase in the concentration of carbon dioxide in the atmosphere.

- A 50% reduction in the area of forest fires is being implemented (in accordance with the Decree of the President of the Russian Federation) by 2030, with this indicator being maintained in the future.

The real decarbonization scenario takes into account the difficulties associated with the radical restructuring of all sectors of the economy - from energy to forestry - and is characterized by the following parameters:

- The rate of reduction of specific (per capita) anthropogenic greenhouse gas emissions corresponds to the moderate indicators achieved in Japan and Canada in the period from 1990 to 2020, and amounts to 0.5% per year, which is significantly better than current Russian indicators.

- Forest management indicators follow current international recommendations and are based on the results of official forest inventories and the Forest Strategy 2030, taking into account the real prospects for the development of the forest sector and the dynamics of carbon absorption by forest biota , according to which the net carbon sink shows a slight increase. In this scenario, ageing forests lose their bioproductivity , but technically and economically feasible forest climate projects are implemented in forestry , while the fight against forest fires achieves limited success.

Acknowledgments

The work was carried out within the framework of the state assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 075-03-2021-074/4).

Abstract

This paper focuses on global climate change and the balance of global temperatures. It has been established that CO_2 emissions and solar activity exert the greatest influence on changes in average temperatures.
The study explores the relationship between average temperature changes, the rate of solar energy input, CO_2 concentration, and cyclical periods. It was found that CO_2 emissions can be significantly reduced. The findings indicate that even with reductions and minimization of CO_2 emissions, such as on the European continent, the average temperature increase observed over the past 48–50 years will not decrease, and a return to the temperature levels of 100 years ago is not feasible. However, it is possible to project the stabilization of this increase at around 1.5°C.
Furthermore, this research highlights the critical link between CO_2 emissions, solar activity, and the broader natural and technological risks associated with climate change. These risks include extreme weather events, natural disasters, and impacts on industrial processes, underscoring the importance of innovative methodologies and practices for risk mitigation.

Keywords: climate change, CO_2 emissions, solar activity, temperature balance, sunspot activity, climate change, climate-related risks, and statistical model

I. Introduction

Climate change has a profound impact on people, the economy, and the environment. Extreme heat was recorded in 2023, leading to droughts and wildfires. In Europe, sea surface temperatures increased further, reaching record highs. Simultaneously, glaciers began to melt. The year 2023 was the warmest on record in Western and Southwestern European countries. The levels of carbon, nitrogen oxides, methane, and chlorofluorocarbons, which contribute to the greenhouse effect, are rapidly increasing due to emissions from industrial facilities and transportation. Consequently, the frequency of storms, blizzards, and floods has risen. According to the International Meteorological Organization (European Union Climate Change Program), the rate of warming in Europe has more than doubled compared to the global average since 1980. In 2023, the average temperature in Europe increased by 2.13°C. [1,2]. Climate change is one of the most significant challenges faced by scientists and engineers. A pressing scientific issue is whether the global rise in average temperatures could ever return to previous levels, what challenges and risks exist along this path, and what efforts will be required to achieve it. In other words, is it possible to achieve global climate equilibrium (temperature equilibrium)?

In light of the ongoing shifts in global energy strategies, particularly the transition from traditional fossil fuels to more sustainable chemical processes, it becomes increasingly important to consider the broader implications of these changes on climate dynamics. The evolution from "crude oil to chem" and emerging technologies like "carbon to chem" highlight how industrial innovations are responding to environmental pressures. These advancements underscore the necessity of integrating such forward-looking approaches into climate risk assessments, particularly when considering the potential impacts on CO_2 emissions and their role in global temperature regulation [3].The objective of this research is to investigate the emergence of global climate equilibrium. Atmospheric pollutants include greenhouse gases (GHGs) that block thermal radiation from the Earth while allowing heat from the Sun to reach the Earth's surface. Industrial greenhouse gases (IGHGs) refer to gases released into the atmosphere as a result of fuel combustion and other economic activities. The formation of IGHGs involves the following gases: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), perfluorocarbons (CF_4, C_2F_6), halogenated hydrocarbons, sulfur hexafluoride (SF_6), and ammonia (NH_3). Additionally, indirect greenhouse gases, which are also pollutants, include nitrogen oxides (NOx) and other volatile organic compounds (VOCs).

The list of harmful substances polluting the atmosphere includes: carbon compounds (oxides); sulfur compounds (hydrogen sulfide, sulfur dioxide, and sulfur trioxide); nitrogen compounds (ammonia, nitrogen oxides, etc.); halogens (their chlorine, fluorine, bromine compounds, etc.); hydrocarbons (benzene, toluene, xylene); alcohols (methanol, ethanol, etc.); ethers; and aerosols of various origins—dust, smoke, and fog.These substances pollute the atmosphere both directly and through oxidation and conversion into other harmful compounds.The primary sources of atmospheric pollution are the metallurgical, cement, chemical, and petrochemical industries, thermal power plants, residential and industrial boilers, and transportation. Among these gases, carbon dioxide (CO_2 equivalent) was specifically mentioned in the study. Using this gas as an example, the study examines all gases contributing to the formation of the greenhouse effect [4-7].

It is well established that climate change is occurring and average temperatures are rising, as shown in Table 1. The primary factors influencing average temperature are the concentration of CO2 in the atmosphere (greenhouse effect) and solar activity. Other anomalous conditions may also arise during this time. Given these considerations, scientific research in this area is ongoing. Over the past 100 years, average temperature increases have been studied across different continents worldwide. Factors affecting the rise in average temperature have been identified, and statistical indicators have been used to analyze the annual average temperature increases across the continents of Europe, North and South America, Asia, Africa, and Oceania.

The factors most significantly influencing the rise in average global temperatures are primarily linked to human activities. These factors include:

1. Fossil fuel combustion:

- The burning of fossil fuels, such as coal, oil, and natural gas, releases large amounts of carbon dioxide (CO_2) and other greenhouse gases into the atmosphere. These gases trap solar heat, leading to an increase in atmospheric temperatures.

2. Deforestation:

- Deforestation leads to the release of carbon into the atmosphere. Trees absorb carbon dioxide through photosynthesis, and a reduction in this process increases carbon levels in the atmosphere.

3. Industrial processes:

- Industrial activities, including metal production, cement manufacturing, and other processes, are significant sources of greenhouse gases.

4. Agricultural activities:

- Agricultural practices, particularly the raising of livestock and rice cultivation, are major sources of methane (CH_4) emissions. Methane is a very potent greenhouse gas, more effective than carbon dioxide.

5. Waste management:

- Methane and other greenhouse gases are released into the atmosphere due to improper waste handling and landfill operations.

6. Transportation:

- Vehicles such as cars, trucks, airplanes, and ships burn fossil fuels and emit greenhouse gases into the atmosphere.

7. Energy use:

- The production and use of electricity result in the emission of large quantities of greenhouse gases, especially when energy is generated from fossil fuels.

These factors are the primary contributors to the rise in average global temperatures. To combat climate change, it is essential to implement measures to manage and reduce these factors.

Heat (solar radiation) reaching Earth from the sun can vary depending on several factors. These changes can be short-term or long-term and are mainly associated with the following factors:

1. Solar activity:

- Solar activity changes in 11-year cycles. During these periods, the number of sunspots and the intensity of solar radiation fluctuate. When there are more sunspots, solar radiation slightly increases.

2. Earth's orbital parameters:

- These changes, known as Milankovitch cycles, are related to the eccentricity of Earth's orbit, axial tilt, and precession (the wobble of Earth's axis). These variations affect the amount of solar radiation reaching Earth over millennia and can lead to glacial periods.

3. Dust and aerosols in the atmosphere:

- Volcanic eruptions or large-scale wildfires release significant amounts of dust and aerosols into the atmosphere. These particles can block sunlight from reaching Earth's surface, causing a global cooling effect. For example, the eruption of Mount Pinatubo in 1991 led to a temporary decrease in global temperatures for several years.

4. Human activities:

- Aerosol emissions into the atmosphere from human activities (e.g., industrial processes and fuel combustion) can reflect solar radiation, but this effect is short-lived and does not fully offset the global warming effect caused by greenhouse gases.

5. The role of clouds:

- Clouds can both reflect and absorb solar radiation, altering the amount of solar energy that reaches Earth's surface. This cloud effect depends on the type, height, and density of the clouds.

6. Changes in Earth's albedo:

- The albedo of Earth's surface, or its ability to reflect sunlight, also affects how solar radiation is perceived. For example, snow and ice have a high albedo and reflect sunlight. As ice melts, darker surfaces (water and land) are exposed, absorbing more solar radiation and increasing temperatures.

The factors mentioned above determine the amount of heat that reaches Earth from the sun and its impact on the planet. Human activities, particularly the emission of greenhouse gases, disrupt Earth's energy balance and lead to global warming. While changes in solar radiation can cause short-term climate variations, the current trend of global warming is largely the result of human activity.

The statistical mathematical model was constructed based on statistical indicators using the example of the European continent. Climate change and its causes were studied through certain simplifications using these established statistical models. The average temperature increase from 1900 to 2023 was analyzed based on statistical data. A multifactorial experimental design matrix was developed using these indicators [8, 9]. The coded level values and the parameter variation intervals affecting the increase in average temperature, as determined by the coefficients, are described in Table 1.

Table 1: *Coded Levels and Parameter Variation Ranges Affecting the Increase in Average Temperature Across Factors*

Factor Names	Coded Levels			Variation Interval
	-1	0	+1	
X_1, CO_2 Concentration, ppm	1.4	2.3	3.2	0.9
X_2, Solar Activity, m/s	200	292	384	92
X_3, Duration, years	50	100	150	50

The multifactorial design matrix is presented in Table 2.

Table 2: *Multifactorial Design Matrix*

№	CO2 Concentration, ppm	Solar Activity, m/s	Duration, years	Output Parameter (Average Temperature),°C
1	1,4	200	50	0.1
2	1,4	200	50	0.2
3	1,4	200	50	0.3
4	1,4	292	100	0.4
5	1,4	292	100	0.5
6	1,4	292	100	0.6
7	1,4	384	150	0.7
8	1,4	384	150	0.8
9	1,4	384	150	0.9
10	2.3	200	100	1
11	2.3	200	100	1.1
12	2.3	200	100	1.2
13	2.3	292	150	1.3
14	2.3	292	150	1.4
15	2.3	292	150	1.5
16	2.3	384	50	1.6
17	2.3	384	50	1.7
18	2.3	384	50	1.82
19	4,6	200	150	1.84
20	4,6	200	150	1.86
21	4,6	200	150	1.88
22	4,6	292	50	1.9
23	4,6	292	50	1.95
24	4,6	292	50	1.98
25	4,6	384	100	2
26	4,6	384	100	2.1
27	4,6	384	100	2.15

Table 2 presents the results of the average annual temperature calculations depending on various factors. As a result, the following regression equation was obtained using the formula (2):

$$Y = b_0 + \sum_{i=1}^{n} b_i x_i + \sum_{\substack{i.j=1 \\ i \neq j}}^{n} b_{ij} x_i x_j + \sum_{i=1}^{n} b_{ii} x_i^2 \quad (1)$$

Here, x_i – represents the factors in the climate change process; n - is the number of factor, *bi, bij, bii* - the coefficients in the regression equation represent linear, interaction, and quadratic effects, respectively. In this study, the number of factors is 3. The regression coefficients are determined using the following well-known formula:

$$b_i = \frac{\partial f}{\partial x_i};\ b_{ij} = \frac{\partial^2 f}{\partial x_i \partial x_j};\ b_{ii} = \frac{\partial^2 f}{2\partial {x_i}^2} \quad (2)$$

$$Y_{temp} = 1.2881 - 0,7881C_{CO_{2(1,4)}} + 0.01141C_{CO_{2(2,3)}} + 0.6741C_{CO_{2(4,6)}} - 0.2348G_{a(200)} - 0.0070G_{a(292)} + 0.2419G_{a(384)} - 0.0048P_{50} - 0.0604P_{100} + 0.0652P_{150} \quad (3)$$

Here, $C_{CO_2} - CO_2$ concentration, G_a - galactic solar activity, P – time (cycle period)

$$Y_{temp} = 17.333 - 0.305x_3 - 0.96x_1^2 - 0.757x_2^2 - 0.486x_3^2 \quad (4)$$

$$Y_{temp} = 13.4259 - 0.3204C_{co_{2(1,4)}} - 0.0370C_{co_{2(2,3)}} + 0.3574C_{co_{2(3,2)}} - 0.1859G_{a(200)} + 0.0263G_{a(292)} + 0.1596G_{a(384)} - 0.0470P_{10} + 0.0763P_{60} - 0.0293P_{110} \quad (5)$$

$$Y_{temp} = 15,4000 - 0,7444C_{co_{2(1,4)}} - 0.1444C_{co_{2(2,3)}} + 0.8889C_{co_{2(3,2)}} - 0.1644G_{a(200)} + 0.0089G_{a(292)} + 0.1556G_{a(384)} + 0.1800P_{0} - 0.0133P_{50} - 0.1667P_{100} \quad (6)$$

Equations (3) and (4) represent linear and nonlinear regression models of the change in average temperature over 100 years on the European continent. Equations (5) and (6) are regression models of the average temperature on the European continent as it stands now and 100 years ago [9].

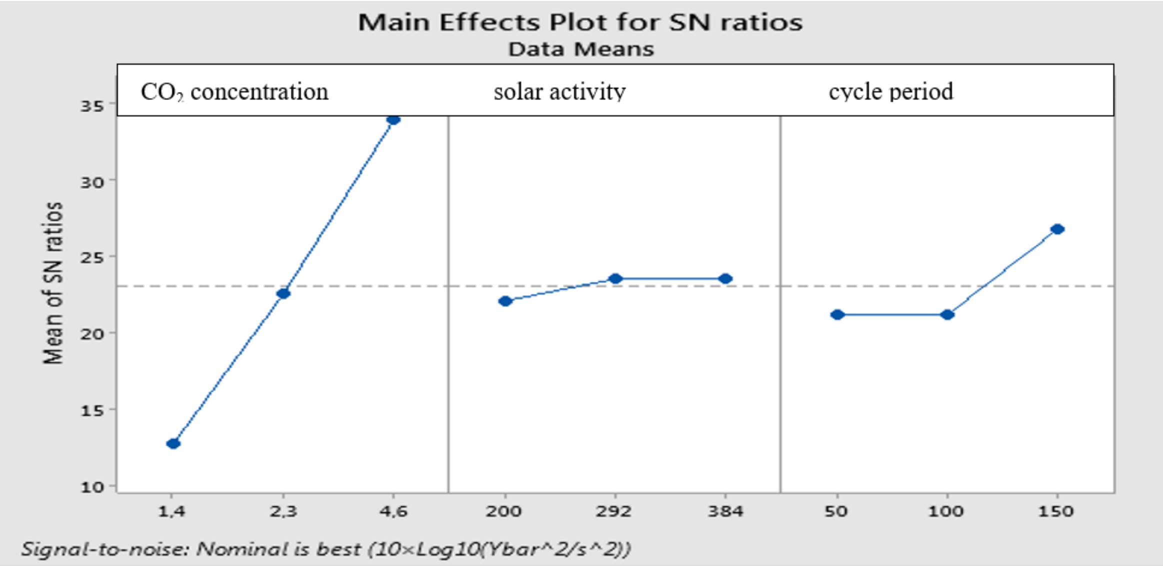

Figure 1: *Relationship between the increase in ambient temperature and CO_2 concentration, solar energy input rate (solar activity), and cycle period*

Processes in the environment, including continental temperatures, change according to nonlinear patterns [10, 11]. It is known from synergetic that nonlinear systems can be characterized by minimal energy dissipation [8]. Most natural processes are studied as nonlinear processes. Chaotic temperature fluctuations require the use of random functions. The method of E. Lorenz can be applied for the analysis of random functions [12, 13]. During this time, unstable harmonic oscillations (peaks) are separated, and the effects of other oscillations are ignored for simplicity.

$$\frac{dx}{d\tau} = k \cdot (y - x) \tag{7}$$

$$\frac{dy}{d\tau} = -x \cdot z + r \cdot x - y \tag{8}$$

$$\frac{dz}{d\tau} = x \cdot y - b \cdot z \tag{9}$$

Here, r = R, R - Rayleigh number, k - Prandtl number, b - constants

Preliminary calculations indicated that linear regression models, in comparison to nonlinear regression models, demonstrate certain minor inaccuracies. These inaccuracies are partially mitigated through the application of nonlinear regression. The relationships between atmospheric temperature, CO_2 concentration, and solar activity across different continents were analyzed. Earth's ecological systems are inherently complex, interconnected, and self-regulating. Addressing the challenges posed by these systems necessitates consideration of their intrinsic natural laws, suggesting that the study of complex ecological systems is fundamentally reliant on experimental calculations.

Research Results and Analysis

The results of the computational experiment examining the relationship between changes in ambient temperature, CO_2 emissions, and the period (time) of solar energy input, as the output parameter, are presented in Figure 1. The impact of all three factors on the outcome, as well as their interaction effects, was analyzed using the statistical software packages "Minitab" and "Origin" based on the obtained statistical data. An increase in CO_2 concentration led to a rise in ambient temperature. The temperature increased as solar activity intensified and then remained constant. Over a 50-year period, the temperature changed little when the CO_2 concentration remained constant. In the following 50 years, the temperature increased. Figure 2 shows a normal probability plot. Figure 3 presents a contour plot of temperature dependence on the rate of solar energy input and the cycle period. The figure shows that temperature significantly varies depending on solar activity and the time of year. Figure 4 illustrates the relationship between temperature and CO_2 concentration over time. In this case, CO_2 concentration and the cycle period greatly influence the temperature. Figure 5 depicts the relationship between temperature, CO_2 concentration, and solar activity. The figure shows that as CO_2 concentration and solar energy increase, the temperature change also increases significantly. During the study, CO_2 concentration was identified as the most harmful gas released into the environment. However, other gas emissions also have consequences. Figure 6 shows bubble charts of temperature changes. The images indicate that CO_2 concentration and solar activity have the most significant impact on temperature change [14, 15]. Here, synergistic processes become more pronounced.

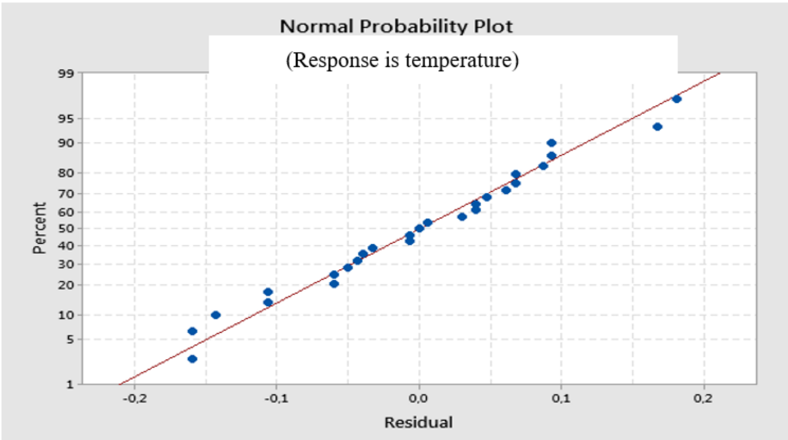

Figure 2: *Normal Probability Plot*

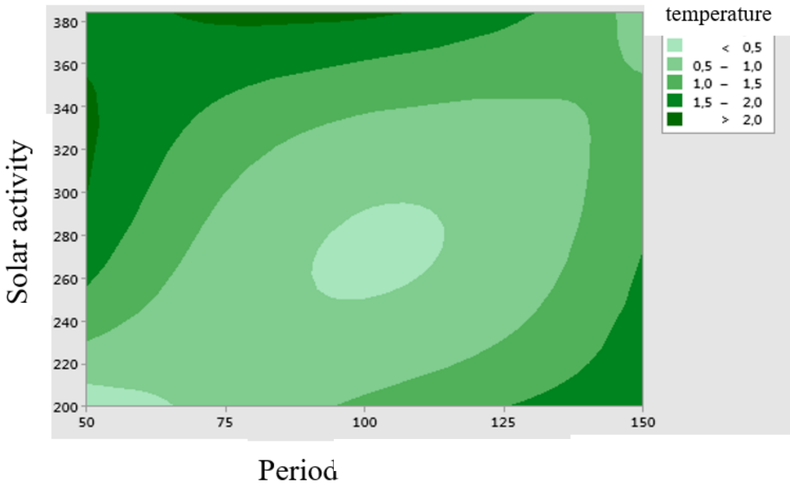

Figure 3: *Temperature Dependence on Solar Energy and Cycle Period*

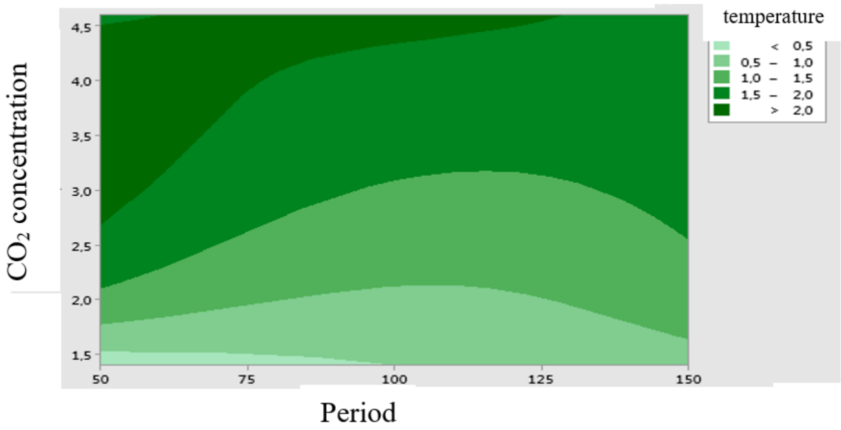

Figure 4: *Temperature Dependence on CO_2 Concentration and Period*

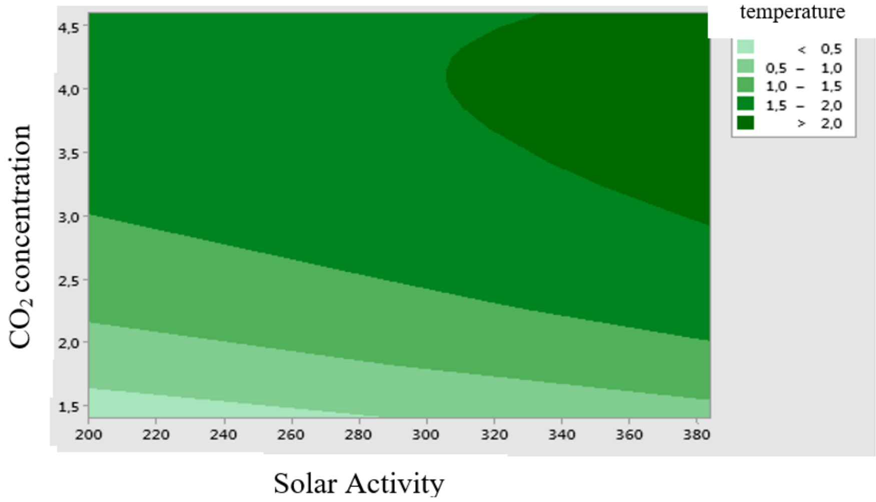

Figure 5: *Temperature Dependence on CO_2 Concentration and Solar Activity*

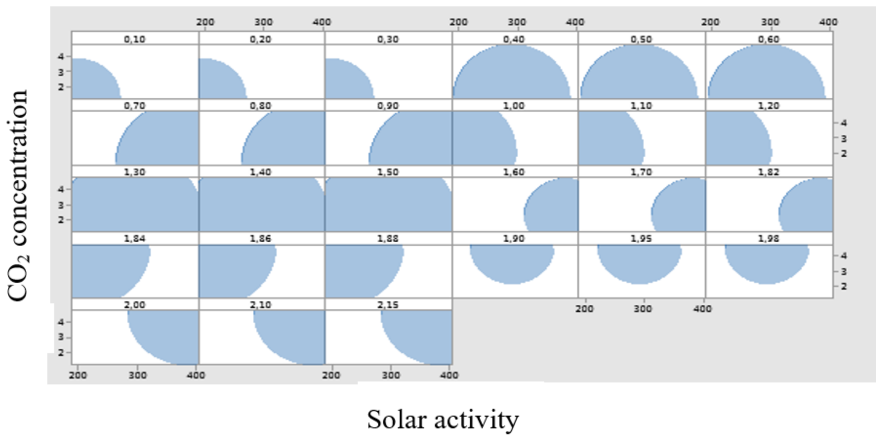

Figure 6: *Bubble Chart of Temperature Changes Depending on CO_2 Concentration and Solar Activity*

Environmental protection from harmful and hazardous industrial and transportation emissions is one of humanity's global challenges. Currently, scientists and engineers face the critical issue of preventing the pollution of the biosphere by CO_2 and other substances. Under these circumstances, it is necessary to develop a methodology for calculating harmful gases, including CO_2, emitted into the environment. The Department of Chemical Technology, Processing, and Ecology at Azerbaijan Technical University has developed a new methodology (using Python software) for calculating the quantity of harmful gases released into the atmosphere. Figure 7 shows the relationship between surface area temperature and solar activity and period. The figure reveals that the temperature variation is complex and has a specific volume depending on the cycle period and solar activity. Figure 8 illustrates the relationship between temperature variation area and CO_2 concentration and cycle period. The figure shows that the surface area does not have a complex structure but rather a convex surface. Figure 9 also shows the relationship between surface temperature variation, solar activity, and CO_2 concentration. In this case, the surface is convex and does not have a specific volume. Figures 7-9 demonstrate that temperature variation is highly dependent on the mentioned factors. However, as shown in Figure 7, the temperature variation surface has a specific volume depending on the cycle period and solar activity. This indicates that the relationship is complex and nonlinear.

Results

CO_2 emissions and solar activity exert the greatest influence on global temperature changes. While humans cannot interfere with the Sun's activity, substantial reductions in CO_2, methane, and other IGHG emissions are possible. Other effects also depend on these two factors. Climate change is an extremely complex process, and there is a degree of randomness involved. The increase in CO_2 emissions is directly linked to human activities, including industrialization, wars, and other factors.

From the obtained graphs and calculations, it is evident that by reducing and minimizing CO_2 emissions, it is possible to forecast a likelihood of temperature reduction over the past 48-50 years and a return to the baseline temperature observed 100 years ago. However, this outcome underscores the broader principle that the more damage humanity causes to nature, the more severe the environmental consequences become.

Over the past 100 years, the Earth's average temperature has risen significantly. This increase is primarily attributed to the emissions of greenhouse gases (CO_2, CH_4, and others) resulting from human activities. Climate change has led to numerous severe consequences, including global warming, desertification, glacier melting, sea level rise, the destruction of small islands, and an increase in extreme weather events. The risk of progressive degradation of the global ecological system continues to grow.

Restoring the Earth's average temperature to its previous state is quite challenging and depends on several factors:

1. Reduction of greenhouse gas emissions: First and foremost, it is essential to significantly reduce the concentration of greenhouse gases in the atmosphere. This requires a rapid decrease in global carbon emissions and the implementation of technologies and policies aimed at removing greater amounts of carbon from the atmosphere.

2. Technological Innovations: Carbon capture and storage (CCS) technologies, methods for removing carbon from the atmosphere, and the widespread adoption of alternative energy sources are crucial.

3. Protection and Restoration of Natural Ecosystems: Natural methods, such as forest conservation, reforestation, and enhancing the carbon capture capacity of soil and oceans, also play a critical role.

4. Global Policy and Cooperation: Combating climate change requires global cooperation. Under international agreements like the United Nations Framework Convention on Climate Change (UNFCCC), the Paris Agreement, the Katowice Climate Package, and the Glasgow Climate Pact, it is crucial for countries to work together, adhere to their targets, and take significant steps in this direction.

Given these factors, the implementation of long-term strategies and systematic efforts is essential to attempt the restoration of global average temperatures to their historical norms. However, climatologists caution that some impacts may already be irreversible. At best, global warming might be limited and eventually halted, but achieving a full return to previous temperature levels will be an arduous, protracted, and costly endeavor.

Abstract

This article focuses on the development and implementation of a system of climate change statistical indicators in the Kyrgyz Republic. It discusses the methodological approaches and practical results of the first experience of creating a systematic set of climate change statistics and integrating them into national decision-making processes for climate adaptation in the Kyrgyz Republic.

Keywords: statistics, climate change indicators, climate change adaptation, climate risks

I. Introduction

Climate change is one of the defining challenges of this decade, with both direct and indirect impacts on key services and infrastructure that affect human well-being and the economy including healthcare, water supply and sanitation, construction, and electricity. Climate change poses an immediate physical risk to the very existence of a facility or region. For example, the destruction of a production site due to an extreme weather event increases the likelihood of a default by the operating company. Climate change also presents a significant financial risk. Climate adaptation measures, as well as global responses to climate threats (such as reducing greenhouse gas emissions and adaptation programs), can have far-reaching consequences for the structure and functioning of global and national economies and financial system [1].

Climate risk encompasses a range of hazards, from extreme weather events to long-term shifts in weather patterns. According to a report by the WMO, the number of natural disasters has increased by five times since 1970, while economic losses have risen even more – by seven times [2].

The situation is especially tense in Central Asia, where warming is occurring faster than the global average, and its rate has almost doubled compared to the period from 1961 to 1990. Record-high temperatures and dry conditions in the Eastern Himalayas and most of the Tien Shan region have accelerated the mass loss of many regional glaciers, which will soon limit access to drinking and irrigation water, create problems in the hydropower sector, and affect agriculture. As the frequency of intense rainfall increases, mudslides and floods will become more common, while more frequent heatwaves will contribute to droughts and cause issues in the healthcare sector.

By 2050, Central Asia may see the emergence of 5 million climate migrants[1]. These climate-related risks exist alongside other challenges, such as misinformation, geopolitical competition, and inflation, and are key risks in 2024 and beyond[2]. It's also important to note that as the frequency and severity of natural disasters (e.g., floods, mudslides) increase, the costs of damage compensation continue to rise[3].

For these reasons, most countries (198 as of early 2022) have not only declared their willingness to adapt to climate change but also recognized the importance of achieving carbon neutrality. However, this progress has been slow and disproportionate to the growing climate risks. For instance, only 4.5% of countries have already achieved carbon neutrality, 10.6% have declared or committed to reaching carbon neutrality goals, 8.6% have enacted laws to achieve these goals, 29.3% have developed policies for achieving carbon neutrality, while the remaining 47% of countries are still discussing relevant documents [3].

The main reason for this situation is that climate risks are just one part of systemic risks. According to the UN Department of Economic and Social Affairs, if the transition to a zero-emissions economy is hastened without systemic changes (including in the field of information provision), the risks to financial stability could intensify [1].

These systemic consequences are essential to consider, as climate change is not an isolated issue – it has a substantial impact on all economic activities and efforts to ensure the well-being and quality of life for the population. The increasing climate risks require systemic changes across all areas of economic activity and the incorporation of climate concerns into national policies.

There is an urgent need for a new paradigm that combines traditional hydrometeorological research and data with climate adaptation studies, services, and assessments, reflected in national statistics. Given the importance of formalized government statistical data, the UN Department of Statistics even suggests that climate can be defined as the statistics of weather over a randomly determined period [1]. The value of reliable government statistical data becomes even more critical as the volume of fake news in the information space grows.

This article presents the methodological approaches and practical results of the first experience in developing a systematic set of reliable statistical data and integrating it into national climate adaptation decision-making processes in the Kyrgyz Republic[4].

II. Methodology

Modern climate management relies on accurate and accessible statistical and departmental data. The volume of climate data is growing exponentially due to the rapid expansion of both observation capabilities and computational power, driven by an improved understanding of climate processes, increased forecast accuracy, and advances in modeling.

Remote sensing data of the Earth's surface is also becoming more accessible for assessing long-term changes, complementing traditional climate observations and statistics (see Figure 1). Similar trends are observed in climate statistics, which have significantly expanded in recent years. Global sets of climate data and indicators, the UNECE set of climate change statistical indicators, the UN System of Environmental-Economic Accounting (SEEA) indicators, and international climate information databases are actively used.

[4] The research was carried out within the framework of the UNDP project "Promoting the process of developing a National Adaptation Plan (NAP) for medium-term and long-term planning and implementation of adaptation measures to climate change in the Kyrgyz Republic"

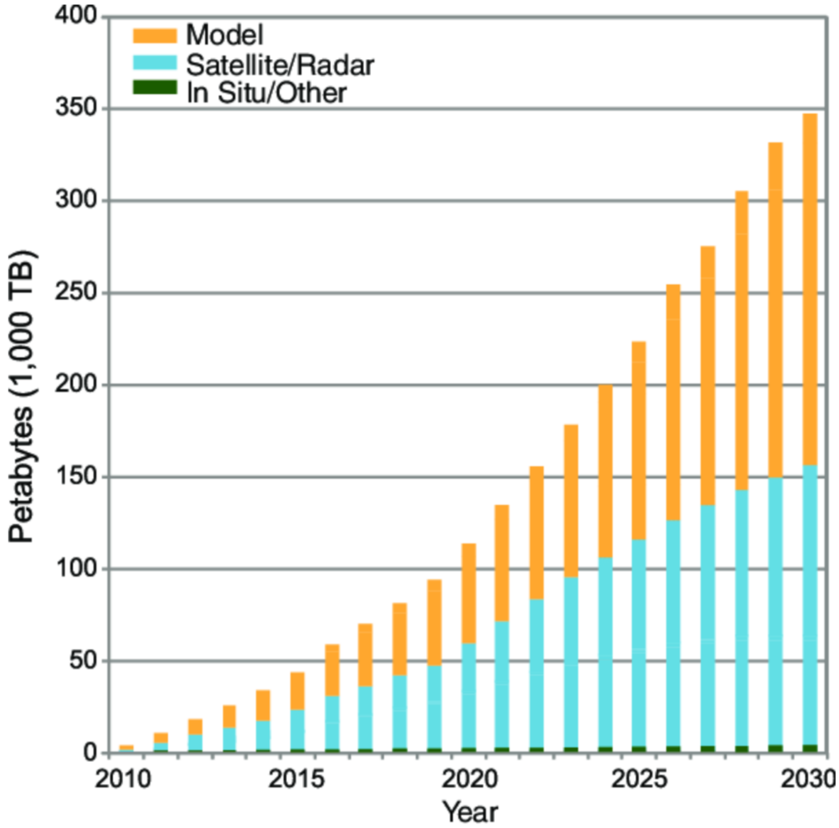

Figure 1: *Projected increase in global climate data for climate models, remote sensing data, and in situ instrumental/proxy data.*

Source: [4].

Understanding this, Infrastructure Panel (WIP) of the World Climate Research Programme (WCRP) and the Working Group on Climate Modeling (WGCM) were established 10 years ago. Their recommendations for global data infrastructure are based on several principles, starting with the need to separate requirements, implementation, and operations. Other important principles include considering the diverse needs of the data community (the data ecosystem), the importance of origin, the need for automation, and the commitment to measuring costs and benefits. WIP recommendations focus on requirements that take into account the diversity of the participating communities (model developers, analysts, software developers, and end-users). These requirements include the need for scientific reproducibility and accountability, as well as the need to register and track data usage. One key element is to focus on data sets rather than systems, aiming to make infrastructure less prone to systemic failures.

Despite this, climate data today are still full of gaps, hindering informed decision-making for managing climate risks. The rapid growth of global climate data also presents challenges in terms of physical archiving and sharing, as well as ease of access and search, especially for non-climate specialists.

A need for a new climate data paradigm is emerging in response to the constantly increasing volume of data, which should: (1) ensure free access to high-quality and reliable measurements for broad scientific research; (2) improve usefulness and clarity for a wide interdisciplinary audience; and (3) integrate climate risks into national and regional governance systems. Moreover, the channels through which climate shocks can be transmitted and amplified through the financial system are being actively studied [5].

In this new climate data paradigm, we believe that the focus should be on compressing information and converting it into indicators that are understandable to policymakers, government specialists, businesses, and the general public. Furthermore, these indicators should ideally have the status of official statistics, as today's global information network is overwhelmed with false information (up to 60%), much of which is generated by bots (up to 40%) [6]. In addition to traditional statistics, "diagnostics," which is used to assess the nature of climate changes over various time scales, is also useful [7].

As a methodological platform for implementing climate statistics in public administration and risk management, it is advisable to adopt the standardized and internationally recognized System of Environmental-Economic Accounting and Ecosystem Accounting (SEEA-EA) [8], which is actively being implemented in national statistical systems worldwide. With its network and hierarchical structure, SEEA can serve as the core of a territorial climate change information system. It includes data on greenhouse gas emissions, the turnover of low-carbon technologies in the national economy, the carbon footprint of national products, the size and condition of various ecosystems and their vulnerabilities, the mitigation and adaptation functions of ecosystems, the impact of ecosystems on the national greenhouse gas balance, and more. Additionally, the Global Set of Climate Change Statistics and Indicators is largely (14% of indicators) composed of SEEA-EA-generated data, and the UNECE set of climate change statistical indicators is almost entirely (more than 60%) made up of SEEA-EA indicators. The SEEA-EA is also being developed in relation to the Classification of the Functions of Government[5]. Furthermore, harmonized climate measurements with the SEEA-EA have been developed in recent years under the G20 Data Gaps Initiative (DGI-3). This is expected to provide policymakers with an expanded toolkit for developing economic and financial policies to address climate change issues in conjunction with financial innovations and inclusive growth. Therefore, the UN SEEA-EA Standard [9-11] can set the basic requirements for the development and implementation of climate statistics in public administration and risk management to better represent opportunities for sustainable investment, innovation, and insurance in an unstable and changing external environment.

III. Results

The interdisciplinary research on the formation and strengthening of climate-related information support was conducted as part of the development of the National Adaptation Plan (NAP) for medium- and long-term planning and implementation of climate change adaptation measures in the Kyrgyz Republic, on assignment from the UNDP office in the Kyrgyz Republic. This research included methodological developments and practical steps to establish a broad system of climate services in the country and to build the capacity of two governmental bodies: the National Statistical Committee and the Hydrometeorological Service of the Kyrgyz Republic, both of which are authorized to produce and disseminate climate information with official state status. The findings of the research, as presented in this article, initiated the establishment of climate change statistics in the Kyrgyz Republic. The key events and outcomes of the Project can be considered as milestones in the development of national climate change statistics (see Figure 2).

[5] The Classification of Functions of Government (COFOG), developed by the OECD, categorizes government expenditure data from the System of National Accounts by the purpose for which the funds are used.

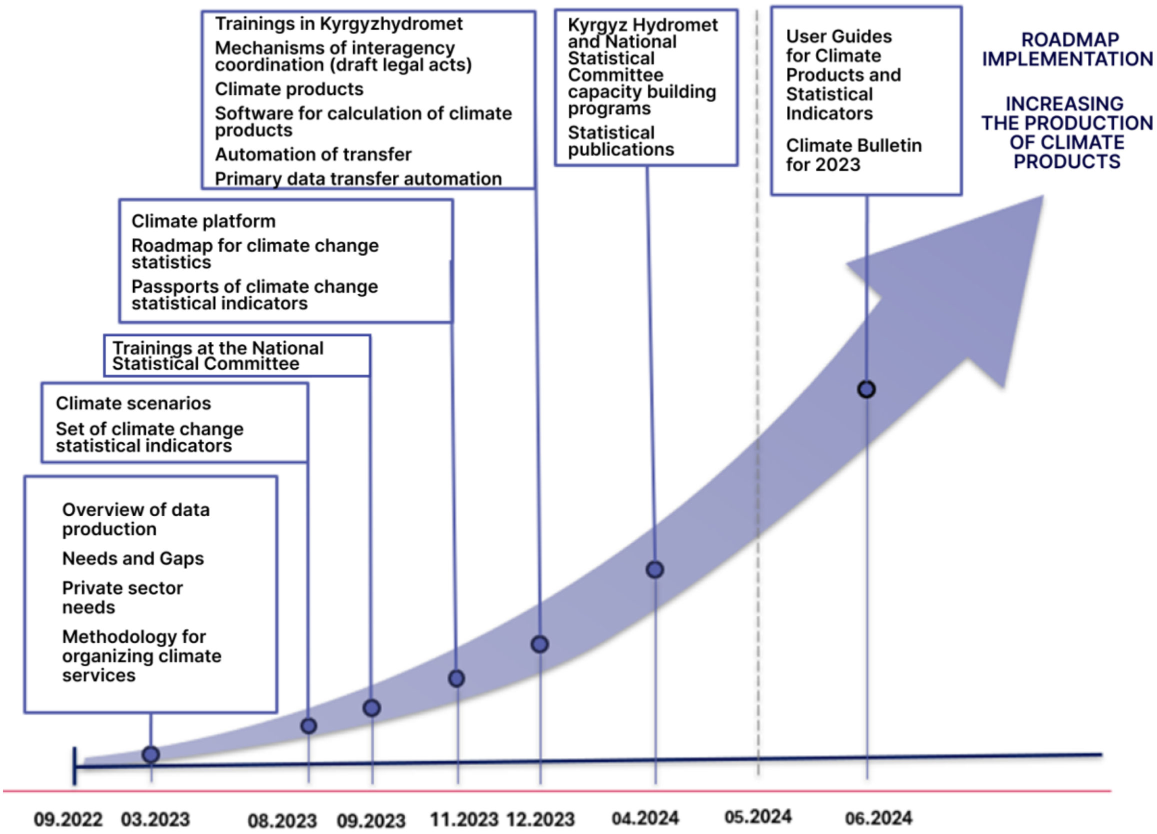

Figure 2: *The Process and Outcomes of the Project in the Establishment of New Climate Change Statistics in the Kyrgyz Republic*

Firstly, a significant characteristic of the Project was the development and implementation of a methodological approach aimed at effective planning that focuses on achieving specific outcomes[6] in improving the system of climate change statistical monitoring. This approach aims to increase the resilience of a wide range of stakeholders to climate change risks.

The systematic nature of the developed approach is defined by the complexity of climate change issues. The negative impacts and the risks they create affect the social, economic, environmental, and institutional aspects of sustainable development for regions and economic entities. An integrated "top-down" and "bottom-up" approach was implemented. Numerous meetings, trainings, and joint discussions identified the need to avoid the trap of system-bound analysis that relies solely on local knowledge, while also incorporating local institutional conditions, generational wisdom, and informal, socio-culturally driven factors and phenomena.

The research and decision-making were based on two planning principles: (1) an incremental approach, which is step-by-step progress, where decisions are made gradually as participants in discussions gather new information, and (2) a protective approach, prioritizing the interests of vulnerable and socially disadvantaged populations. Through mutual adaptation among stakeholders, actions were implemented progressively, considering all economic, environmental, social, political, cultural, and other conditions.

This methodological choice explains the significant number of interactive meetings involving the National Statistical Committee of the Kyrgyz Republic and the Hydrometeorological Service of the Kyrgyz Republic, with broad participation from government experts, members of the interagency working group on climate change indicators, and representatives from the real sector of the economy. These interdisciplinary discussions not only educated participants on the basics and specifics of climate statistics but also helped create indicators using the Global Set of Climate Change Statistics and other international recommendations. Over 500 people participated in 24

[6] The term "effective planning" currently refers to specific activities that lead to change [12].

training sessions, with more than 60% being women. The importance of women's traditionally strong role in Kyrgyz society and the need to formalize this role in public interactions were emphasized. Protecting the rights of rural widows to access water in conditions of water scarcity was also highlighted.

This approach enabled the gradual and multifaceted development of the set of climate change statistical indicators, their consideration by agencies and the private sector, and the formal development of each indicator and their metadata passports. As a result, by 2025, a significant portion of climate statistics will be published regularly. An important element of effective medium- and long-term planning was the creation of a Roadmap for the development of climate change statistics in the Kyrgyz Republic, which is essential for the successful introduction of new indicators into official statistics.

Secondly, a mechanism has been initiated in the Kyrgyz Republic for implementing climate change indicators within the institutional framework to enhance the resilience of climate-vulnerable sectors of the economy and a wide range of stakeholders to both current and future climate risks.

The availability of quality measurements for research and planning activities has improved, and the range of available hydrometeorological indicators has expanded. A new section in the official statistics of the Kyrgyz Republic has been developed – the "Climate Change Statistics" section, which includes 95 indicators grouped by specialized topics (drivers, impacts, vulnerability, mitigation, adaptation) and economic sectors (agriculture and irrigation, health, disaster risk management, biodiversity conservation and forestry, water management, urban areas, waste, industrial processes and product use, energy). This reflects various aspects of the climate agenda – hydrometeorological, environmental, socio-economic, demographic, and institutional. This is a foundational and pioneering step for many countries, not only in the development of official statistics but also in the national system of climate monitoring and services. Additionally, the project developed specialized climate indices and products. Before the project, only three hydrometeorological indicators were included in official statistics; now, there are 14.

As part of this project, research on current climate change and projections for the end of the century was conducted using two selected greenhouse gas emission scenarios, SSP5-8.5 and SSP2-4.5. Homogenized monthly temperature and precipitation data from 22 meteorological stations in Kyrgyzstan for the period 1980-2021 were used. Eleven climate products and methodologies for their calculation were developed to improve the quality of hydrometeorological data, and these were included in the national climate change statistical indicators by the National Statistical Committee of the Kyrgyz Republic. The basis for development was the WMO climate indices, which assess the impact of current climate and its changes on various socio-economic conditions in Kyrgyzstan. Climate products were calculated for the period 1980-2022 based on data from 13 meteorological stations in different climatic regions of Kyrgyzstan.

The development and first releases of the statistical publication "Climate Change Indicators in the Kyrgyz Republic" and the climate bulletin "Current State and Climate Change in the Kyrgyz Republic for 2023" will undoubtedly raise awareness among a wide range of stakeholders, with further editions planned on a regular basis. Additionally, two user manuals have been developed for the first time: a Climate Products User Manual and a Climate Change Statistical Indicators User Manual.

The priority focus is on expanding the understanding of climate vulnerability in the economic sectors of the Kyrgyz Republic. This ensures that a broad audience can comprehend the information and make relevant and rational decisions. During training presentations and open discussions, participants reflected on which physical climate threats hinder the development of vulnerable sectors and challenge public health and emergency systems. They were guided by an expanded understanding of the involved actors, considering the needs of government authorities, private sector representatives, and households. As a result, a set of statistical indicators was developed that covers a wide range of climate-related issues and phenomena, reducing climate vulnerability.

For example, despite data production challenges, the indicator "water reserves in glaciers" was adopted. It was recognized that as glaciers are predicted to melt, water scarcity issues will intensify, both for the Kyrgyz Republic and neighboring Central Asian countries. A gender-inclusive indicator was adopted: "The proportion of the population without access to centralized life-support systems (water supply, heating, cooling), including persons with disabilities and households that have lost a male breadwinner."

It is also significant that as a result of the project, the skills of the National Statistical Committee and the Hydrometeorological Service of the Kyrgyz Republic in constructive interaction with users of climate information have been enhanced, including their ability to listen to real needs and willingness to develop in response to those needs.

To ensure the integration of climate risks into the management system of the Kyrgyz Republic, a set of measures on institutional, organizational, technical, and operational support was implemented. Institutionally, the following were prepared: (1) Proposals to amend regulatory and legal acts of the Kyrgyz Republic in the field of hydrometeorology and official statistics in terms of climate information production and provision; (2) Draft regulatory and legal acts to establish interagency coordination mechanisms; (3) A roadmap for improving climate change statistics in the Kyrgyz Republic; (4) Institutional mechanisms for interagency cooperation to develop a climate change statistical database in the Kyrgyz Republic and maximize the use of available statistical and departmental information resources.

Organizationally, the following were developed: (1) Proposals for changes to the structure of the Hydrometeorological Service's departments related to climate data and index production and provision; (2) Proposals for changes to the structure of the National Statistical Committee's departments related to climate data and index production and provision; (3) Long-term capacity-building programs for the National Statistical Committee and the Hydrometeorological Service of the Kyrgyz Republic, which were approved by the heads of these agencies.

Technically, the following were proposed: (1) Software and databases for calculating climate products (indices) for the Hydrometeorological Service of the Kyrgyz Republic; (2) Software for calculating climate products; (3) Databases for climate information production.

To institutionalize operational processes[7], the following were developed: (1) Recommendations for climate product production and climate change statistical indicator data production; (2) Guidelines for interagency coordination in producing official climate change statistics; (3) Materials for creating and maintaining a platform for interaction with the private sector.

Thirdly, a significant step was taken in developing a broad climate service system in the Kyrgyz Republic to increase the resilience of a wide range of stakeholders to climate risks and uncertainties.

For the first time in Central Asia, methodological recommendations were made for the development of a national climate service system, covering providers, mainly the National Statistical Committee and the Hydrometeorological Service of the Kyrgyz Republic, and a wide range of consumers (see Figure 3). Climate service is defined as the provision of climate information for making the best decisions by individuals and organizations. The focus was on the chain of climate information production and provision, viewed as the subject of climate service and integrating climate data[8] and climate products[9].

[7] In this case, an operational process is a regularly repeated sequence of activities that transforms primary data into climate indices and climate data that are made available to stakeholders.
[8] Climate data are historical and real-time climate observations and direct model outputs covering historical and future periods. All climate data should be accompanied by information on how these observational data and model outputs were derived ("metadata")
[9] Climate products are summarized climate data. Products combine climate data with climate knowledge to enhance their value for adaptive management. Its use in the management process allows the climate factor to be adequately valued, thereby ensuring, as far as possible, that adaptive capacity is enhanced through climate informed decision-making [13].

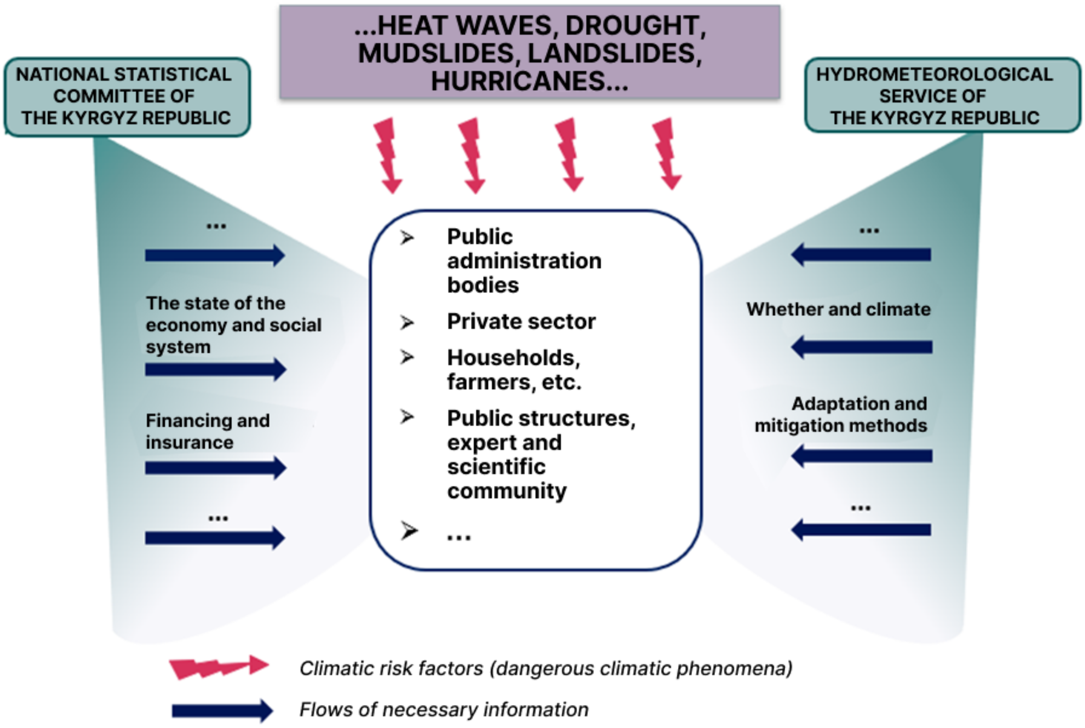

Figure 3: *Climate Service – A Necessary Factor for the Successful Implementation of the Climate Agenda of the Kyrgyz Republic*

A well-established and responsive climate service system creates the foundation for effective actions to reduce climate risks, adapt to climate change, and mitigate negative climate impacts. It is a broad yet targeted system addressing the problems and needs of a wide range of stakeholders. This includes diverse but crucial information – about weather and climate, past and future events, long-term trends, threats, and opportunities. This information is essential for making practical decisions regarding sector management, avoiding business losses, preventing threats to health and human life, and protecting material objects and infrastructure.

A significant focus during the project was on motivating and educating users about the relevance of climate information for various stakeholders – including specialists from territorial management bodies, sectors of the economy, representatives of large businesses and small producers, households, banks, credit organizations, insurance companies, public, and non-commercial entities. Each of these stakeholders has its own goals and perspectives on climate risks, but they all share a need for reliable and timely climate data.

All project activities were aimed at enhancing the capacity for producing and providing climate information by key climate service providers – the state agencies in meteorology and statistics. Their role as providers of reliable data is increasingly important in a world characterized by rising misinformation. The work of these agencies covers every link in the information production chain, including data collection, regular data processing, storage, provision, and the development and implementation of new climate indicators, all of which are legally and methodologically substantiated and supported by qualified personnel. Each stage of the process undergoes verification.

IV. Discussion

The climate agenda of the Kyrgyz Republic must be harmonized with global sustainable development goals (SDGs) and the overall systemic Concept of National Security of the country[10]. Defining and quantifying "climate change risk," with relevant measurement indicators, is central to analyzing development processes, as it is fundamental for assessing the socio-economic consequences of climate change. This, in turn, is crucial for planning effective, impactful, and fair climate adaptation and mitigation strategies. Extensive literature discusses the challenges, methods, results, and development of this fruitful research area, which has been evolving for nearly 40 years [14-18].

Today, the importance of creating effective climate statistics in every country is widely recognized. For example, in the Kyrgyz Republic, climate statistics have already been identified as a crucial and timely response to contemporary climate challenges. This significance is justified by the following premises:

- It is essential to improve the quality and availability of climate data, as the more we know about the climate crisis, the better we can identify and manage climate risks. Climate data will help analyze risks affecting the economy, monetary policy, price stability, and the financial system more effectively.
- The role of official government data needs to be strengthened; for instance, for the widespread adoption of climate insurance, which, according to UNDP, will become as significant as investments and innovations in the coming years.
- Transparency in climate-related issues must be ensured, and the quality of economic evaluation of targeted projects should be improved when transitioning to a green economy (cost-benefit analysis).

The special significance of the implemented project and its results lies in the initiation of a new trend in the development of statistics and meteorological support. The development of the indicator system and roadmap, and their integration into a unified statistical observation system in the Kyrgyz Republic, turned out to be a complex interdisciplinary and research-intensive task, as climate change impacts social, economic, environmental, and institutional aspects. Moreover, climate impacts are intertwined with increasing anthropogenic pressures on water, food, energy, biodiversity resources, inequality, and poverty.

The particular characteristic of the present time is that new concepts, terms, and institutions related to climate change and its impacts on various aspects of public life are becoming part of community and state life, expert discourse, official rhetoric, and decision-making systems. These are relatively new phenomena, yet climate challenges increasingly demand action, creating a need for new measurements and indicators. In this context, the project implemented comprehensive measures for institutional, organizational, technical, and operational support of new management actions within the climate agenda, ensuring that new "rules of the game" complement existing norms, rules, and practices without contradicting them. Thus, the following were ensured at each stage:

- Alignment with the needs of climate-vulnerable sectors and other stakeholders in the Kyrgyz Republic;
- Adherence to international recommendations and best practices;
- Consistency with existing local institutional and organizational conditions, including the ability to produce climate information and enable users to understand how to use it effectively.

Internationally, the project has localized the UN Global Statistical Indicators to the Kyrgyz

[10] Concept of National Security of the Kyrgyz Republic (Decree of the President of the Kyrgyz Republic of December 20, 2021 № 570).

Republic, adapting them to local needs and conditions for reducing climate risks and uncertainties. Each indicator has been developed with a metadata passport. Another significant result is the set of climate products developed with the help of international consultants on our project. Importantly, these climate products are included in the statistical set for the first time. This grants them high national status – at the level of official statistics, with regular production and publication of data, which undoubtedly indicates the systematic approach of the Kyrgyz Republic to assessing climate risks and threats, as well as to monitoring and transparency in climate actions. This represents an important innovative step in improving climate service formats.

V. Conclusions

The study of potential directions for the development and mechanisms of implementing climate change statistics in the Kyrgyz Republic, as an informational basis for reducing climate risks, led to several conclusions important both theoretically and practically.

Theoretically, with the increasing climate burden, defining and quantifying "climate change risk," as well as developing corresponding measurement indicators, is essential for analyzing the development processes of the Kyrgyz Republic. The reason is that without measuring risk reflection, planning climate risk reduction measures and conducting environmental and socio-economic assessments of climate change consequences are impossible.

The development of an adapted system of climate statistics indicators for the Kyrgyz Republic is the foundation for planning effective, impactful, and fair climate strategies (adaptation and mitigation). This indicator system should meet the basic requirements of the *new paradigm* of climate data in the context of growing volumes at global and national levels. The new system of climate change statistical indicators should: ensure free access to high-quality and reliable measurements for scientific research, enhance the utility and comprehensibility of climate information and data for a broad interdisciplinary audience, and integrate climate risks into country and regional management systems, covering a range of dangers from extreme weather events to long-term climate changes.

Since climate impacts affect systemic aspects of sustainable development, methodological approaches should combine "top-down" and "bottom-up" approaches, as well as incremental and protectionist approaches to planning.

Practically, new realities in the climate agenda in the Kyrgyz Republic, as in many other countries, involve increased demands and a transition to a new qualitative level for national statistical and meteorological services. These services are required to expand and strengthen their skills to provide adequate responses to new needs for reliable climate data, update their systematic scientific and calculation bases for producing climate data, and ensure regular publication. Enhancing the significance of these services on international platforms, such as the UN, WMO, and Eurostat, is also crucial. Such transformations will undoubtedly contribute to strengthening and substantively developing the Kyrgyz Republic's image as an active player in the international climate agenda.

Acknowledgments

We express our gratitude to the UNDP Kyrgyz Republic office managers for their skilled and knowledgeable leadership, to representatives from ministries and agencies, the private sector, and the expert and scientific community for their interest and active participation. Our special thanks go to the management and leading specialists of the National Statistical Committee of the Kyrgyz Republic and the Kyrgyz Hydrometeorological Service for their constructive cooperation, friendly attitude, and patience.

Abstract

The environmental challenges posed by conventional energy production necessitate a shift towards sustainable alternatives. This study explores the potential of solar power, particularly focusing on Solar Power Tower (SPT) systems utilizing the supercritical carbon dioxide (sCO_2) Brayton cycle, as a viable solution to reduce carbon emission in Azerbaijan. Through data collection and analysis, the study evaluates the efficiency and feasibility of SPT systems. Results indicate that the sCO_2 Brayton cycle offers a net cycle efficiency of 50.8%, surpassing traditional power generation methods. The Direct Normal Irradiance (DNI) analysis identifies the Nakhchivan Autonomous Republic as an optimal location for deploying SPT technology due to its high DNI levels. This transition to advanced solar technologies promises to meet rising energy demands, reduce carbon emissions, and mitigate environmental degradation, aligning with global efforts to address climate change and secure a sustainable future.

Keywords: solar energy, concentrated solar power, solar power tower, supercritical CO_2, photovoltaic, power cycles, sustainable energy

I. Introduction

Most current types of energy production and utilization cause environmental issues at local, regional, and global scales, reducing the quality of life and endangering human health. Fossil-fueled power plants produce large amounts of environmentally harmful emissions of gases such as carbon dioxide (CO_2). In 2023, the total CO_2 emissions from energy-related activities increased by 1.1% compared to the previous year. This rise pushed total CO_2 emissions to a record high of 37.4 billion tones [1]. Furthermore, worldwide energy demand is expected to rise approximately 1.5–3 times by 2050 [2]. By 2025, it is projected that the CO_2 intensity of global power generation will attain a level of 417 grams of CO_2 emitted per kilowatt-hour (g CO_2/kWh) [3]. This record-high level of emissions highlights the need for action to reduce carbon emissions, as these high levels significantly worsen global climate change. Thus, there is a pressing need to use renewable energy resources, such as solar, wind, hydropower, and biomass, instead of fossil fuels for energy generation. 26.49% of the world's electricity production comes from renewable energy sources [4], but for Azerbaijan, this figure is 20.3% [5].

The most developed form of renewable energy in Azerbaijan is hydropower, but in 2022, severe droughts recorded in several countries led to a decrease in confidence in hydropower [6]. On the other hand, solar energy has the highest economic potential among renewable energy sources. On average, each square meter of Earth receives roughly 342 watts of solar energy in a year [7]. This amounts to an enormous total energy input of 44 quadrillion (4.4×10^{16}) watts [7]. In Azerbaijan, the economic potential of solar energy sources is 23,000 MW [5], exceeding the economic potential of other renewable sources. Therefore, it is essential to develop solar energy, considering its vast potential globally and in Azerbaijan.

Solar energy stands out as an affordable renewable energy source with significant potential to generate clean and environmentally friendly energy. Solar radiation can be transformed into either heat or electricity through diverse solar conversion technologies. Solar energy conversion technologies can be classified into solar photovoltaic (PV) and concentrated solar power (CSP) systems. Solar photovoltaic systems directly transform solar radiation into electricity, whereas concentrated solar power systems convert solar radiation into heat energy. Solar power plants installed in Azerbaijan are all based on PV technology. However, CSP offers several advantages over PV systems. Thus, this study will focus on the potential installation of CSP technology in Azerbaijan.

Concentrated Solar Power (CSP) is a technology capable of large-scale electricity generation, providing reliable energy and the ability to deliver power on demand through thermal energy storage. CSP plants offer advantages such as high efficiency and the capability to accumulate heat, enabling operation nearly around the clock. Accumulating heat in CSP technology helps generate electricity when desired and stabilizes and controls power generation. CSP plants produce 33.3% more electrical energy compared to PV plants. [8]. Many positive aspects of CSP-type power plants make the installation and operation of this technology more appropriate. There are four distinct types of concentrated solar power systems: parabolic dish, parabolic trough, solar power tower, and Linear Fresnel reflector. They differ in how the sun's rays are concentrated in the receiver.

Solar Power Tower (SPT) technology is a promising option due to its wide temperature range, comparable cost per kilowatt, and longer storage durations [9]. SPT power plants work with the Rankine cycle. Rankin is pretty advanced, so there's little room for improvement. The simple Rankine cycle can achieve an efficiency of up to 29.6% [10], and specific studies indicate that this can potentially be improved to as much as 41% [11]. On the other hand, when supercritical carbon dioxide (SCO_2) is used as the working fluid in the Brayton cycle, the work efficiency appears to exceed 50% [12]. Supercritical CO_2 Brayton cycles can increase power plant capacity and efficiency, which will play a role in improving SPT technology [9].

In this paper, we investigate the potential of SPT power plants in reducing CO_2 emissions in Azerbaijan. We analyze the sCO_2 Brayton recompression cycle, develop a numerical model of an SPT plant, and propose a suitable region for its installation in the country. The results highlight the environmental benefits and feasibility of using SPT technology in Azerbaijan's shift towards renewable energy.

II. sCO_2 Brayton Recompression Cycle

Our study examines the sCO_2 (supercritical carbon dioxide) Brayton recompression cycle [13]. The recompression cycle reduces inefficiencies in the internal heat recovery process by using two recuperators and adding a secondary compressor. The cycle starts by compressing sCO_2 from low to high pressure with a compressor. As the sCO_2 is compressed, its temperature increases significantly due to its high heat capacity. Under these conditions, the sCO_2 enters the heat exchanger from the compressor, where it receives heat from an external source. In the heat exchanger, thermal energy from the Solar Power Tower heats the sCO_2, further increasing its temperature and pressure. The high-temperature, high-pressure sCO_2 then expands through a turbine, converting thermal energy into mechanical work. This turbine drives a generator to produce electrical power. After expansion, the sCO_2 enters the heat exchanger at a lower temperature and pressure to release the absorbed heat, reducing its temperature and preparing it for the next cycle. At reduced pressure and temperature, the sCO_2 is recompressed by the compressor to initiate the subsequent cycle.

Fig. 1 demonstrates a schematic representation of this cycle, which serves as the foundational framework for modeling an SPT power plant.

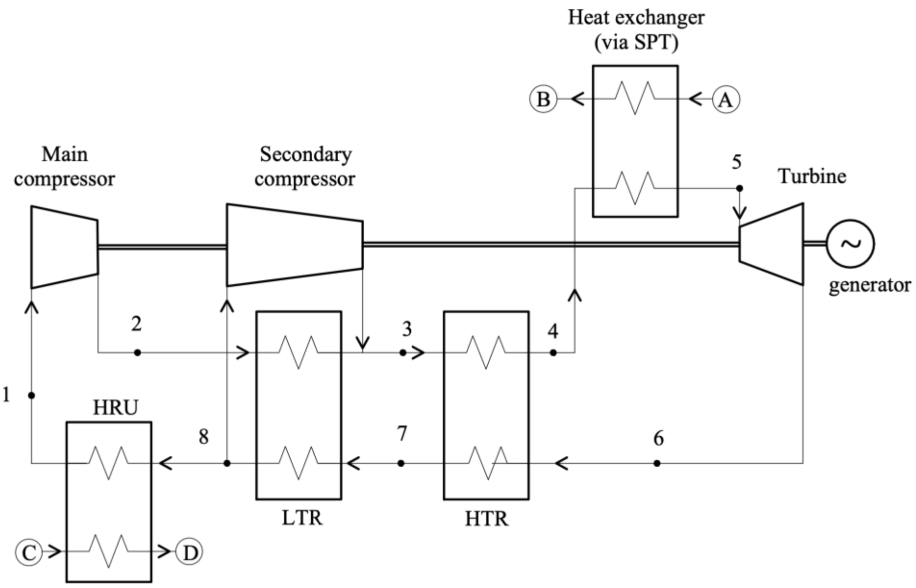

Figure 1: *Schematic of the sCO_2 Brayton recompression cycle [13]*

III. Methods

The numerical model of the sCO_2 cycle for the SPT power plant was constructed using Mathcad software. The numerical model uses primary assumptions outlined in Table 1.

Table 1: *Main assumptions for the sCO_2 cycle*

Parameter	Value	Parameter	Value
Heliostat field, F_H, m^2	67	Maximum cycle temperature, t_0, °C	650
Heliostat reflectance, R_H	0,82	Maximum cycle pressure, P_{max}, MPa	25
Maximum irradiance of the heliostat mirror E_H, W/m^2.	610	Minimum cycle pressure, P_{min}, MPa	10,5
Maximum receiver irradiance, E_i, MW/m^2	1,94	Relative internal turbine efficiency, η	0,84
Receiver absorption coefficient, A_{absorp}	0,95	Receiver emissivity ε_{em}	0,94

Direct Normal Irradiance (DNI) rates were analyzed to determine the optimal area for SPT implementation in Azerbaijan. This analysis was facilitated by utilizing geographic data provided by Solargis [14].

Additionally, we employed a comparative analysis approach to examine CO_2 emissions and technical parameters of the six most powerful non-renewable power plants in Azerbaijan: Shimal, Janub, Sumgayit, Gobu, Sangachal, and Azerbaijan. The parameters selected for this analysis are Capacity (MW), Cycle type, Cycle efficiency, and CO_2 emissions per kWh. Technical parameters were obtained through direct correspondence with the relevant power plant. This analysis was employed to evaluate the reduction in CO_2 emissions by replacing non-renewable power plants with SPT systems.

IV. Result and Discussion

I. Performance of power cycle

Our study began with an examination of the operational mechanisms of the sCO_2 Brayton recompression cycle. We based our calculations on the assumptions outlined in Table 1. We demonstrate the T-s diagram of the sCO_2 Brayton recompression cycle based on our results in Figure 2.

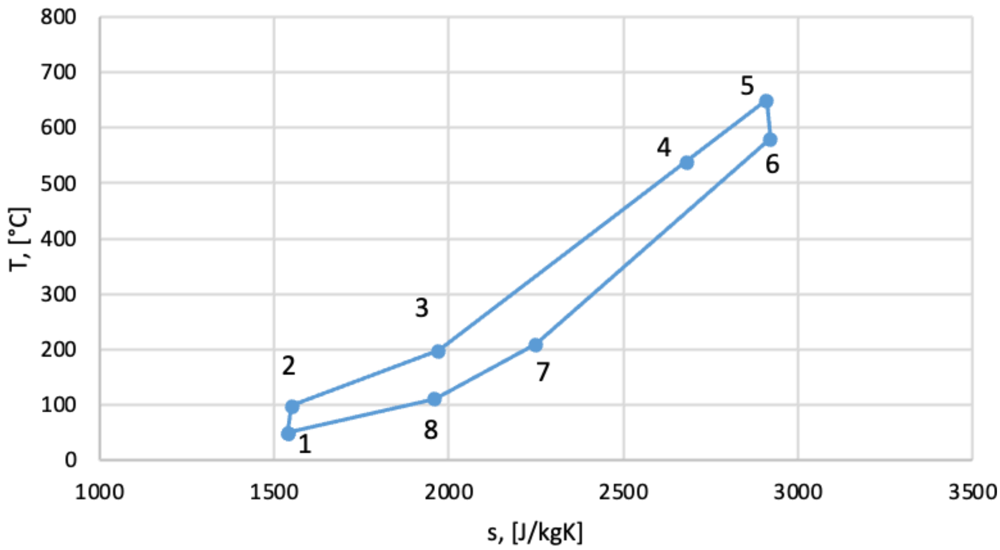

Figure 2: *T-s diagram of sCO_2 Brayton recompression cycle*

Additionally, we documented the outcomes of our calculations in Table 2. This table includes key performance metrics and design specifications such as sCO_2 mass flow, number of heliostats, heat exchanger characteristics, and operational parameters. These results provide a comprehensive overview of the system's performance under the specified conditions, demonstrating the feasibility and efficiency of using sCO_2 in SPT technology. The data in Table 2 are critical for validating the model and comparing the projected performance against conventional power generation systems. The efficiency of the cycle was determined to be 50.8%, indicating that the sCO_2 Brayton cycle is more appropriate for use in SPT plants than the Rankine cycle.

Table 2: *Main results for the sCO_2 cycle*

Parameter	Value	Parameter	Value
CO_2 mass flow at turbine inlet, D_0, kg/s	364	Turbine electric power, **MW**	72.8
Net heat input, Q_{ty} *KW*	107714	Main and secondary compressor electric power, **MW**	10/8
Receiver area, **m²**	57.5	Number of heliostats	3512
Capacity of Solar power tower, N_e, MW	54,8	Net Cycle efficiency, %	50.8

II. Identifying promising regions for Solar Power Tower deployment

Direct Normal Irradiance (DNI) is critical in analyzing a suitable area in Azerbaijan for an SPT. CSP systems, including SPT, concentrate sunlight on a small area to generate high temperatures. This concentration process is effective only with direct sunlight, making DNI an essential parameter for assessing the potential efficiency and viability of the system. High DNI values indicate a greater availability of direct sunlight, which is necessary for optimizing the performance of CSP technologies. The analysis of DNI levels in Azerbaijan, conducted using data from the Solargis [14], reveals several regions with significant potential for the deployment of SPTs. Upon analyzing the DNI maps, the Nakhchivan Autonomous Republic in Azerbaijan emerges as a particularly suitable location for the installation of an SPT power plant. The high DNI levels in this region indicate optimal conditions for the efficient operation of CSP systems, making it a promising site for harnessing solar energy effectively.

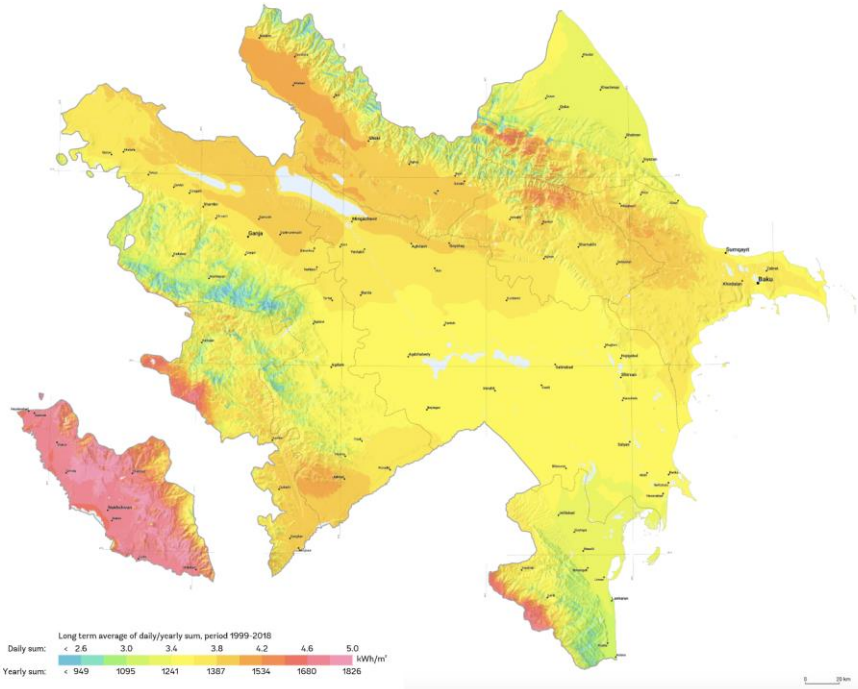

Figure 3: *Direct Normal Irradiation map of Azerbaijan [14]*

III. Potential for emissions reduction through Solar Power Tower

As previously discussed, energy production is a major contributor to environmental pollution. Therefore, it is essential to evaluate the carbon dioxide (CO_2) emissions produced by the operational non-renewable power plants in Azerbaijan. Table 3 provides the technical parameters of operational non-renewable power plants in Azerbaijan, including capacity, cycle type, cycle efficiency, and CO_2 emissions per kWh of electricity generated. The data highlights significant disparities in both capacity and efficiency among the power plants, with capacities ranging from 2400 MW for Azerbaijan TPP to 300 MW for the Sangachal Power Plant. Furthermore, variations in CO_2 emissions per kWh range from 0.414 kg for Shimal Power Plant to 0.538 kg for Azerbaijan TPP, underscoring the importance of technological efficiency in mitigating environmental impact in the energy sector.

Table 3: *Technical parameters of non-renewable power plants in Azerbaijan*

Name of the power plants	Capacity (MW)	Cycle	Efficiency of cycle (%)	CO_2 emitted per kWh (kg)
Azerbaijan TPP	2400	Rankine	37	0.538
Shimal Power Plant	800	Combined	55	0.414
Janub Power Plant	780	Combined	51	0.446

Sumgayit Power Plant	525	Combined	52	0.438
Gobu Power Plant	380	Otto	48	0.464
Sangachal Power Plant	300	Diesel	46	0.495

The data in Table 3 highlights that the Shimal Power Plant, with the highest efficiency, emits 0.414 kg of carbon per kWh of energy production. Replacing this plant with a SPT power plant would reduce CO_2 emissions by 331,200 kilograms per hour.

V. Conclusion

In conclusion, the urgent need to address environmental challenges stemming from conventional energy sources necessitates a transition towards sustainable alternatives. The exploration of solar energy, particularly through advanced technologies like the sCO_2 Brayton cycle, presents a promising pathway toward achieving this transition. By leveraging the efficiency and lower emissions offered by such innovative approaches, Azerbaijan can not only meet rising energy demands but also prevent environmental damage.

The comprehensive analysis conducted in this study underscores the viability and potential of solar power towers (SPT) utilizing the sCO_2 Brayton cycle in Azerbaijan's energy landscape. Through data collection, modeling, and analysis, we have demonstrated the feasibility of integrating advanced technologies into the energy infrastructure, thus opening avenues for a more sustainable future. With a net cycle efficiency of 50.8%, these systems offer a substantial improvement over traditional power generation methods.

Furthermore, the examination of Direct Normal Irradiance (DNI) levels in Azerbaijan reveals promising locations for the deployment of solar power towers, with the Nakhchivan Autonomous Republic emerging as particularly suitable. These regions boast high DNI levels, indicating optimal conditions for harnessing solar energy efficiently and effectively.

By adopting Solar Power Tower technologies with supercritical CO_2 cycles, Azerbaijan and other countries can fulfill their energy requirements while substantially contributing to global efforts to address climate change and safeguard the planet for future generations.

Abstract

This study delves into the economic foundations of sustainable urban development, focusing on the active role of human participation in the transition toward eco-friendly cities. It investigates how sustainable cities balance economic growth, environmental conservation, and social equity, all while adapting to the challenges posed by rapid urbanization, climate change, and resource depletion. The research underscores the role of sustainable economic practices such as renewable energy integration, green infrastructure, and waste reduction in fostering urban resilience. A central theme of the book is the significance of human involvement in driving sustainability efforts. It explores how citizen engagement, policy-making, and community-driven initiatives shape eco-friendly urban landscapes. The book also highlights the economic benefits of public participation in decision-making processes, showing how informed communities can support green innovations and enhance city-wide efforts to reduce environmental impact. By exploring case studies and best practices from cities worldwide, the book demonstrates how human-driven policies and economic strategies can contribute to the development of cities that are environmentally sound, socially inclusive, and economically sustainable. This work serves as a guide for policymakers, urban planners, and citizens aiming to create more livable, sustainable urban spaces.

Keywords: Sustainable urban development, eco-friendly cities, human participation, green infrastructure, circular economy, renewable energy

I. Introduction

As urban populations continue to grow, cities around the world face unprecedented challenges, including environmental degradation, resource scarcity, and social inequality. The concept of sustainable urban development emerges as a critical framework to address these challenges, emphasizing the need for an integrated approach that harmonizes economic growth, environmental protection, and social inclusivity. This paradigm shift requires not only innovative economic strategies but also active human participation in creating eco-friendly urban environments.

Human involvement is crucial in the transition toward sustainable cities, as it fosters a sense of ownership and accountability among community members. Citizens play a vital role in shaping urban policies, influencing consumption patterns, and advocating for environmentally friendly practices. By engaging individuals and communities in decision-making processes, cities can harness local knowledge and foster a culture of sustainability that resonates with residents.

This study aims to explore the economics of sustainable urban development, highlighting the interplay between human participation and the creation of eco-friendly cities. It will examine successful case studies that illustrate how collaborative efforts can lead to innovative solutions, ultimately promoting urban resilience and a higher quality of life. The focus will also be on practical strategies and policies that can facilitate citizen engagement and foster sustainable economic growth in urban settings.

As we navigate the complexities of modern urbanization, understanding the economic implications of sustainable development and the critical role of human participation will be essential in building cities that are not only environmentally sustainable but also socially just and economically viable. Through this exploration, we aim to provide valuable insights for policymakers, urban planners, and community stakeholders striving to create sustainable urban futures.

II. Methods

This study employs three specific methods to investigate the economics of sustainable urban development and the role of human participation in creating eco-friendly cities:

1. Surveys: A structured survey will be administered to residents of selected urban areas. The survey will include quantitative questions designed to assess participants' awareness of sustainable practices, their attitudes toward eco-friendly initiatives, and their level of engagement in local decision-making processes. A sample size of approximately 500 participants will be targeted to ensure a representative cross-section of the urban population. Data from the surveys will be analyzed statistically to identify correlations between citizen participation and perceptions of sustainable urban development.

2. Case Studies: Detailed case studies will be conducted on three cities known for their innovative approaches to sustainable urban development—such as Copenhagen, Singapore, and Vancouver. Each case study will examine the specific policies implemented, the role of community involvement, and the measurable outcomes in terms of environmental sustainability and economic growth. Data will be collected through document analysis, interviews with local stakeholders, and site visits to assess the practical implications of these initiatives.

3. Focus Groups: Focus group discussions will be organized with diverse community members, including local residents, business owners, and representatives from environmental organizations. These discussions will aim to gather qualitative insights into community attitudes toward sustainable urban development, barriers to participation, and suggestions for improvement. Each focus group will consist of 8-10 participants, and sessions will be recorded and transcribed for thematic analysis, allowing for a deeper understanding of collective perspectives and shared experiences related to eco-friendly city initiatives.

III. Results

As the world confronts the growing challenges posed by climate change and environmental degradation, the construction industry has emerged as a key contributor to achieving a sustainable future. Eco-friendly building practices have become essential in this effort, providing innovative solutions that not only meet the immediate demands of urbanization but also protect the planet's long-term health. A core principle of eco-friendly building is the utilization of renewable energy sources. Since buildings are significant energy consumers and reliance on fossil fuels greatly contributes to carbon emissions, integrating technologies such as solar panels, wind turbines, and other renewable energy solutions allows structures to generate clean energy, thereby reducing their dependence on non-renewable resources and minimizing their ecological footprint.

The selection of construction materials is crucial to a building's environmental sustainability. Eco-friendly building practices prioritize the use of green materials, which are defined by their low environmental impact throughout their entire life cycle. This includes materials with recycled content, those sourced from sustainable forests, and products that exhibit a low carbon footprint. Such materials promote a more sustainable construction sector by conserving natural resources and decreasing the emissions associated with conventional materials.

Energy efficiency is central to eco-friendly building practices. Advanced technologies, such as smart building systems, energy-efficient HVAC (heating, ventilation, and air conditioning) systems, and superior insulation methods, optimize energy use within buildings. By implementing these technologies, buildings can significantly lower their energy consumption, which in turn reduces greenhouse gas emissions and reliance on non-renewable energy sources.

Eco-friendly building practices play a vital role in mitigating the carbon footprint linked to the construction and operation of buildings. The use of renewable energy sources and energy-efficient technologies contributes directly to the decrease of greenhouse gas emissions. Additionally, incorporating carbon sequestration strategies, such as green roofs and carbon-absorbing building materials, further helps offset the carbon impact of construction activities. Traditional construction methods typically involve the extraction and consumption of large quantities of natural resources. In contrast, eco-friendly building practices emphasize resource conservation. By utilizing recycled or reclaimed materials, minimizing waste through efficient construction techniques, and selecting materials with lower environmental impacts, these practices help preserve ecosystems and biodiversity. The resilience of the built environment in addressing climate change is a vital aspect of modern construction practices. Eco-friendly building methods enhance the overall resilience of structures by integrating features like climate-responsive design, resistance to natural disasters, and the adaptive reuse of existing buildings. This strategy ensures that buildings can endure the challenges posed by a changing climate, thereby contributing to the longevity and sustainability of the built environment.

In conclusion, eco-friendly building practices signify a transformative shift in the construction industry, moving beyond traditional norms to adopt a sustainable and environmentally conscious approach. The use of renewable energy sources, the integration of green building materials, and the implementation of energy-efficient technologies together redefine how buildings are designed, constructed, and operated. By reducing carbon footprints, conserving natural resources, and bolstering the overall resilience of the built environment, these practices stand as beacons of hope for a more sustainable and ecologically responsible future.

IV. Discussion

The transformative potential of Sustainable Urban Design goes beyond merely environmental aspects; it deeply influences community dynamics and significantly enhances the quality of life for urban residents. This examination delves into the multifaceted impact of Sustainable Urban Design on communities, highlighting its holistic approach to promoting community well-being, fostering a sense of belonging, improving residents' quality of life, and advancing social equity.

Sustainable Urban Design embraces a comprehensive perspective that prioritizes the overall well-being of communities. Recognizing the interplay between social, economic, and environmental factors, this approach shapes the urban experience by addressing the diverse needs and aspirations of community members. The goal is to create inclusive, resilient, and vibrant urban spaces that enhance the collective welfare of residents.

At its core, Sustainable Urban Design is committed to inclusive design principles that guarantee public spaces are accessible and usable for all. This commitment extends beyond mere regulatory compliance; it involves actively engaging with the varied needs of different demographic groups, including people with disabilities, seniors, and children. By incorporating universal design concepts, urban spaces become welcoming and inclusive, fostering a sense of belonging for all.

Moreover, Sustainable Urban Design emphasizes social cohesion and connectivity. The arrangement of urban spaces, the design of public gathering areas, and the creation of pedestrian-friendly environments encourage social interactions and community engagement. Integrating green spaces, parks, and communal areas acts as a catalyst for social cohesion, offering residents opportunities to connect, share experiences, and build a collective identity within their neighborhoods.

The design of sustainable urban environments significantly affects residents' health and well-being. Access to green spaces, walkable neighborhoods, and recreational facilities contributes to physical and mental wellness. Incorporating nature into the urban landscape improves air quality, reduces stress levels, and promotes overall health. Sustainable Urban Design advocates for designs that prioritize public health, acknowledging the link between a healthy environment and individual well-being.

Sustainable Urban Design also aims to enhance living conditions by optimizing resource use and creating comfortable, energy-efficient homes. Energy-efficient buildings that maximize natural light and ventilation not only minimize environmental impact but also provide healthier living spaces. Additionally, mixed-use developments ensure that essential services, educational institutions, and recreational amenities are conveniently located, improving residents' overall quality of life (fig.1).

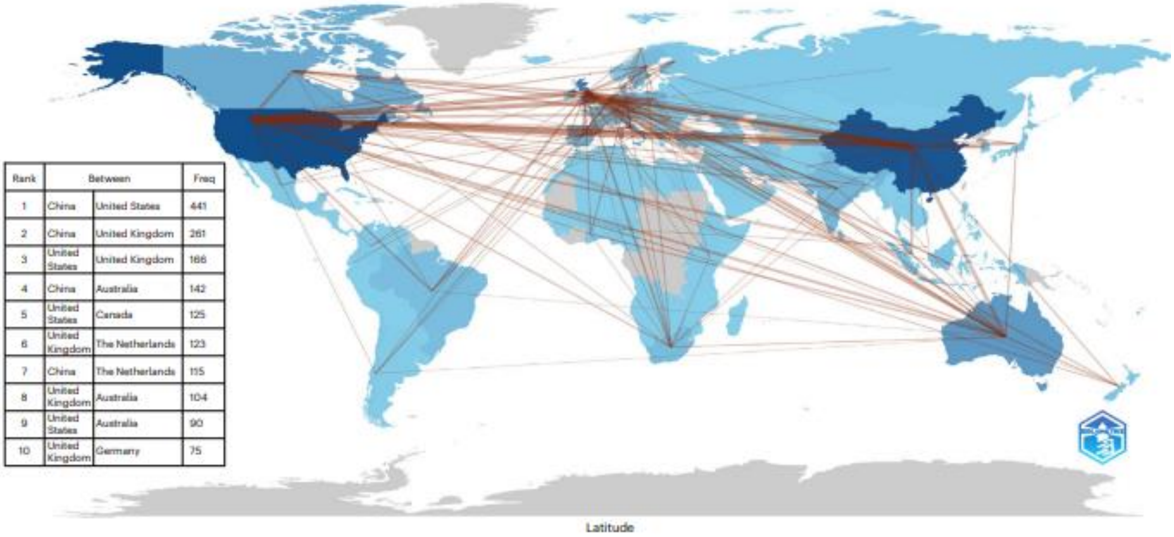

Figure 1: *10 collaborating countries in SDG11 research*

China followed by the United States and the United Kingdom dominates SDG11 research collaborations. There are significant connections among European, North American and Asian institutions, while Africa is less connected with Asia and Latin America and the Caribbean. Freq, frequently.

Equity is a key focus of Sustainable Urban Design, addressing issues of accessibility and affordability. Public infrastructure, including transportation systems and public spaces, is designed with the needs of all residents in mind, especially those with limited mobility or financial resources. Public transportation systems, cycling lanes, and pedestrian-friendly pathways enhance accessibility, ensuring urban amenities are reachable for everyone, regardless of socio-economic status.

Furthermore, Sustainable Urban Design actively tackles socio-economic disparities by promoting inclusive housing policies and equitable development strategies. This includes providing affordable housing, creating mixed-income neighborhoods, and implementing initiatives to prevent gentrification. By encouraging socio-economic diversity within urban areas, Sustainable Urban Design contributes to building resilient communities better equipped to face economic fluctuations and social transformations.

In conclusion, the community impact of Sustainable Urban Design extends beyond physical structures and environmental concerns associated with urban planning. By adopting a holistic approach to community well-being, fostering a sense of belonging, improving residents' quality of life, and promoting social equity, Sustainable Urban Design emerges as a powerful catalyst for positive social change. As cities evolve, the principles of sustainable urban design provide a roadmap for creating urban environments that prioritize the needs of diverse communities, ultimately leading to more livable, inclusive, and equitable urban spaces.

A significant trend of urbanization is unfolding worldwide, with nearly 55% of the global population currently living in urban areas. Projections indicate that this trend will continue, potentially doubling the urban population by 2050. Cities are also responsible for approximately 75% of carbon emissions, 70% of energy consumption, and 80% of global GDP, positioning them at the forefront of the fight for sustainable development and climate action. Effective urban management has the potential to promote sustainable development, leading to increased productivity and innovation. Data clearly illustrates the connections between planned urbanization and human development; however, the prevalence of informal settlements presents a major obstacle to the positive correlation between urban growth and improvements in income, health, and education conditions (see Figure 2).

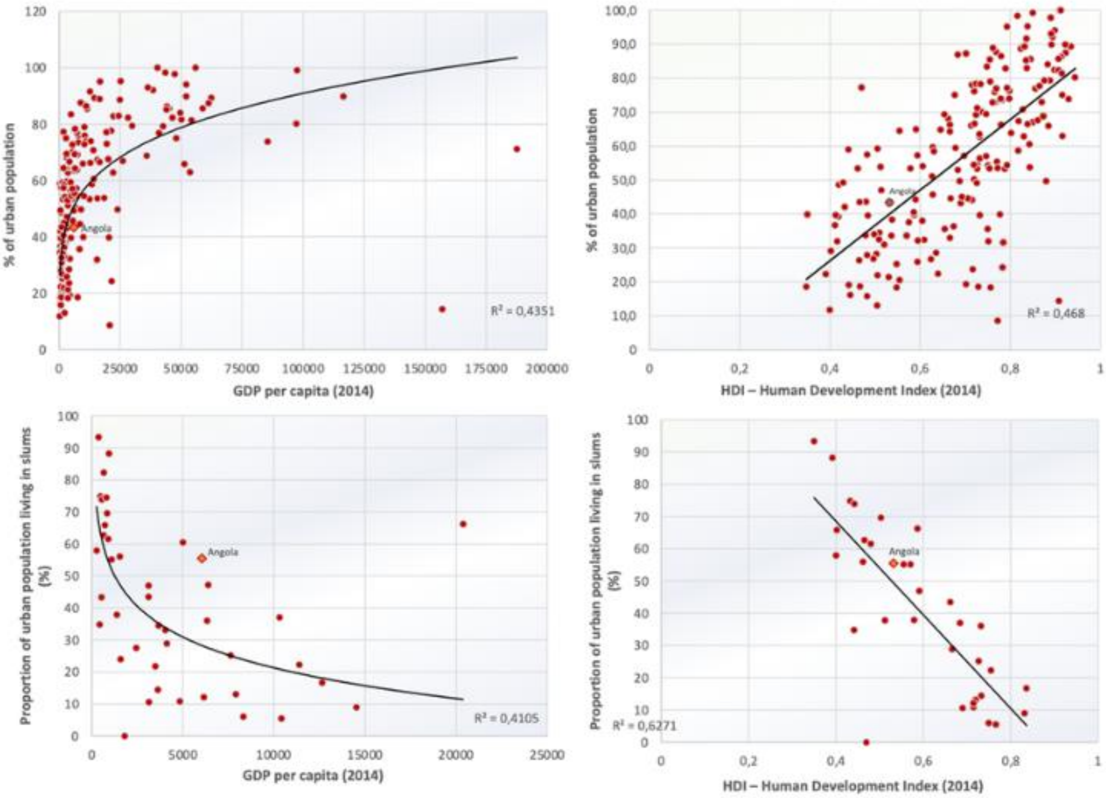

Figure 2: *Correlation between HDI and GDP per capita growth with unplanned urbanization*

There is a broad consensus within the development community regarding the significance of cities and urbanization in achieving sustainable development, as highlighted in recent global agendas. One of the 17 Sustainable Development Goals (SDGs) of the 2030 Agenda is entirely focused on urban issues: SDG 11, which addresses sustainable cities and communities. This goal comprises 10 targets aimed at ensuring that cities and human settlements are inclusive, safe, resilient, and sustainable. However, urban issues extend beyond these specific targets and can be found across all 16 other SDGs, as shown in Figure 03. In addition to these interconnections, urbanization serves as a catalyst for achieving the SDGs, with cities functioning as engines of economic growth, innovation, and socio-economic opportunities.

Building local capacity for urban planning is essential to ensure that urbanization effectively contributes to sustainability. This need is highlighted in the 2030 Agenda under the SDG 11.3 target, which aims to enhance inclusive and sustainable urbanization and capacities for participatory, integrated, and sustainable human settlement planning and management in all countries by 2030. In response to this challenge, UN-Habitat launched a toolbox methodology called "Our City Plans" at the 2020 World Urban Forum. This initiative is designed to support cities in implementing the New Urban Agenda and localizing the SDGs at the community level in a participatory and incremental manner.

Figure 3: *The interconnectivity between SDG 11 targets and other SDGs targets*

The theories and concepts discussed above have shaped and influenced various urban agendas over the past two decades (see Fig.2). Among these, the sustainable city stands out as the most prominent and frequently referenced urban agenda. This concept, rooted in sustainable development (SD) and sustainable city development (SCD), first emerged with the 1994 Aalborg Charter and has been significantly influenced by the UN Agenda 21 and the 2002 Melbourne Principles on Sustainable Cities, which were sponsored by the United Nations Environment Programme (UNEP) and ICLEI.

Different scholars provide varying interpretations of what constitutes a sustainable city. Some view it as a framework for enhanced ecological and resource protection, while others see it as a means to ensure economic growth through greener technologies, balancing ecological stability and social equity—a perspective often referred to as “greener urban growth.” Additionally, some emphasize the importance of addressing all three pillars of sustainability.

Mori and Yamashita provide a comprehensive yet straightforward definition: a sustainable city maximizes socio-economic net benefits while considering environmental constraints and the limits of economic and social inequality. Similarly, Roseland defines a sustainable community, whether urban or rural, as dynamic and engaged in activities that sustain the environment, empower citizens, and ensure that the needs of both current and future generations are met. Scholars also highlight essential characteristics of sustainable urban form: inclusivity and accessibility, health and thoughtful planning, adequate density, energy efficiency, resilience to climate and other risks, economic competitiveness, affordability, protected ecosystems, eco-friendly transportation infrastructure, and robust regional linkages.

In addition to the sustainable city agenda, at least five other prominent urban agendas have been identified in the literature: Ecocity, low-carbon city, resilient city, knowledge city, and smart city. The concepts of green city and livable city are also present but are often regarded as subcategories of ecocity and sustainable city, respectively. Contrary to common assumptions among policymakers, these various agendas do not all share the same theoretical foundations, and their terminologies should not be used interchangeably.

The ecocity and green city concepts, rooted in long-standing principles of deep ecology and the humanities, gained traction in the late 20th century and were primarily operationalized within a broader eco-urbanism movement. Approaches such as eco-districts, zero-carbon cities, and low-impact urban developments align with this spirit of collective sustainability.

On the other hand, smart and digital city agendas focus on utilizing digital technology and infrastructure to enhance well-being, along with a greater emphasis on governance. However, in practice, the smart city agenda often lacks a holistic approach to sustainability, with initiatives that may not adequately address social equity or ecologically responsible resource management. Bibliometric and webometric analyses further reveal a lack of widely accepted definitions or coherent understandings of the smart city agenda, potentially leading to tensions and disconnections in research, policy, and practice.

Abstract

This article explores the challenges of assessing local business activity through the lens of sustainability and innovation in success metrics. Current economic realities and environmental challenges have required the adaptation of traditional assessment methods to adequately reflect all aspects of business impact. The study begins with a critical look at outdated assessment approaches that neglect the long-term perspective and focus on immediate economic results. The paper emphasizes that such methods often ignore a wide range of factors, from the social environment to the environment. The author presents a new model of metrics that balance economic progress with environmental and social responsibility. These metrics place a particular emphasis on combining data on business impact on society and the ecosystem, allowing for a more accurate and comprehensive assessment. To implement the proposed model, attention is paid to the need to create information systems capable of collecting, analyzing, and interpreting data according to the new criteria. This will play a key role in providing regional political and economic leaders with the tools to make informed decisions. The article also illustrates how some regions are already successfully applying these metrics, demonstrating significant progress in their approaches to assessing entrepreneurial activity. These examples confirm the potential for achieving sustainability and well-being through the thoughtful application of these approaches. It concludes by highlighting that the shift to assessing entrepreneurial activity with a sustainable development perspective is not only important for the current state of regions, but also contributes to ensuring a better future.

Keywords: entrepreneurial activity, sustainable development, regional level

I. Introduction

There are over 5.7 million small businesses operating in Russia. These organizations form a critically important share of the country's economic structure, defined by the employment of 10 to 100 people and an annual income of no more than 800 million rubles. A comparison with the number of large (13.6 thousand) and medium (17.9 thousand) enterprises emphasizes their special role: the number of small firms reaches 213.8 thousand.

Over the past decade, the Russian small business segment has undergone a profound transformation and has emerged as a leading element of the economic system.

The prosperity and further development of such enterprises are closely linked to a number of conditions - from the economic to the technological situation both in the regions and in the country as a whole. In light of the above, the task of developing and implementing assessment strategies that will help small businesses meet the criteria for sustainable development is becoming more urgent. These approaches have broad potential: they not only ensure the stability of companies, but also provide tools for monitoring the impact of business processes on the environment and the social environment.

The concept of sustainable development emerged from the awareness of the environmental damage caused by industrialization. A striking echo of this was the London Smog Disaster of 1952, which killed over 12,000 people. This event had a significant impact on the growth of environmental awareness. Then, in 1972, the Club of Rome put forward The Limits to Growth, which outlined twelve prospects for global economic development and emphasized the rational use of resources and demographic regulation. The term "sustainable development" gained wide recognition after the publication of the UN report Our Common Future in 1987, which defined it as development that does not compromise the ability of future generations to meet their own needs. This document, prepared by a commission headed by Gro Harlem Brundtland, became a milestone in the promotion of global sustainability.

In modern Russia, the key importance of sustainability is relevant for small businesses, for which modernization and sustainable growth are becoming a matter of primary attention. The European Union, where about 25 million small and medium-sized enterprises operate, creating more than half of the bloc's GDP and providing jobs for almost 100 million people, can be considered a model for Russia. European SMEs are active in solving global problems, including climate change, rational use of resources and maintaining social sustainability.

Assessing the performance of small businesses based on sustainable development criteria helps not only to adapt to the changing market environment in Russia, but also to make a significant contribution to solving global problems, while strengthening the competitiveness of these enterprises.

II. Methods

This study aims to create a proven assessment approach that will enable small businesses to integrate sustainability principles into their strategies and operations. The analysis examined best practices and tools used in this area, including authoritative methodologies such as Acra, Common Sense, and the National Rating Agency, which specializes in ESG principles. In addition, an extensive review of academic literature and online sources was conducted to identify the most significant elements of sustainability.

Previous research shows that adhering to sustainable practices can increase financial returns by 80%, highlighting the critical importance of such strategic business reorientation. In the Russian context, voluntary adoption of ESG standards beyond statutory requirements is observed, highlighting the market's readiness for deeper integration of sustainable practices.

III. Results

In September 2024 A survey of 4.4 thousand organizations not related to small businesses was conducted. Its results showed that **entrepreneurial activity index** , characterizing the general state of entrepreneurial behavior of organizations, compared to August 2024:

- in extractive industries increased by 0.5 percentage points to 6.2%;
- in the manufacturing sector decreased by 0.1 percentage points to 6.8%.

In September 2023 In 2015, the index of business confidence in the extractive sector of the economy was 2.1%; in the manufacturing sector of the economy – 4.4%.

Entrepreneurial activity index (seasonally adjusted), %

Dynamics of the entrepreneurial activity index , %

	since 2017				
	minimum value		average value	maximum value	
	date	meaning		date	meaning
Mining	May 2020	-13.0	0.3	June 2018	7.8
Manufacturing industries	February 2017	-10.0	-1.0	June 2024	7.0

	2023				2024								
	Sept.	Oct.	Nov.	Dec.	Jan.	Febr.	March	April	May	June	July	Aug.	Sept.
Mining	2.1	1.7	1.7	2.7	5.2	5.1	6.0	4.0	5.1	7.0	6.7	5.7	6.2
Manufacturing industries	4.4	4.5	6.4	5.1	5.8	5.4	6.1	6.8	6.6	7.0	6.9	6.9	6,8

An example of assessing entrepreneurial activity in the extractive and manufacturing industries demonstrates the importance of monitoring the entrepreneurial confidence index. In particular, significant fluctuations have been observed in these sectors since 2017. For example, the minimum value of the index in the extractive industry was recorded in May 2020 (-13%), which can be explained by the global economic consequences of the pandemic. The maximum was reached in June 2018 (7.8%), indicating economic recovery in the post-crisis period.

In manufacturing, the minimum index value (-10%) was observed in February 2017, which was associated with internal economic problems, and the maximum (7.0%) was recorded in June 2024. Such changes show how sensitive this sector is to external and internal factors.

To better understand the current state of regional economies and identify trends, it is necessary to take into account seasonal and structural fluctuations, as well as external factors such as international sanctions, commodity price fluctuations and changes in global trade.

Developing relevant metrics for sustainable development

Based on traditional methods of assessing entrepreneurial activity, it is necessary to supplement them with indicators reflecting sustainability. Such metrics should be adapted to the specifics of specific industries and regions. The following approaches are proposed for this purpose:

1. **Integrated sustainability indices** :
Introduction of indices that integrate economic, environmental and social indicators, allowing to assess not only current production activity but also long-term prospects.
2. **Environmental Performance Indices** :
Develop metrics that measure the impact of production activities on the environment, including emissions, resource use, and waste management.
3. **Social indicators** :
Assessing the impact of companies' activities on social conditions in the region, including job creation, wage levels, participation in social projects and human capital development.

The study and assessment of existing models demonstrates their value as tools for assessing ESG parameters in the activities of enterprises, with a special emphasis on the comprehensive approach proposed by the Acra methodology. Approaches based on the analysis of the processes of individual companies and their compliance with the set ESG goals are actively considered in the scientific community as some of the most promising for achieving results. The study by Shestakov A.B. and Gusev S.A. presents a comparative characteristic of various methods, most of which are based on economic models, while expert approaches presented by such authors as Shesterikov N.V. also find recognition. It is noted that more than two dozen methods for assessing the sustainability of enterprises are described in the scientific literature. Each of them has its own unique characteristics and requires a separate assessment in terms of practical applicability. The key features, advantages and possible disadvantages of these approaches are presented in the table for a clear comparison and ease of subsequent analysis.

The small size and flexibility of management in small businesses contribute to their quick response to market trends and ease of testing innovations. This makes a small enterprise an attractive choice for many citizens wishing to engage in entrepreneurial activity. However, in Russia, the practice of highly targeted use of the potential of small firms in terms of their impact on the sustainability and prosperity of both individual regions and the country as a whole has not yet been established.

Small businesses play a crucial role in stimulating the local economy, improving the social environment and addressing political issues. However, businesses in the Far East face serious economic challenges, including high costs, remoteness from economically developed centres, difficult climatic conditions and increased transport costs. This has traditionally made the region dependent on government subsidies, and the reduction of government support only worsens the situation, reducing the competitiveness of local businesses. Ultimately, this leads to the economic isolation of the Far East from the rest of the country.

The situation is critical in the small business sector, where many companies are in the crisis stage of their life cycle. The problems are exacerbated by their dependence on external financing, limited access to capital and ineffective state support. The high cost of capital and problems with securing ownership often lead to the insolvency of small enterprises, which highlights the need for reforms in this sector to improve their viability and support sustainable development.

To overcome the crisis of small business, a new course is aimed at improving state support and improving financial management within companies. In order for small business prosperity to become a reality, state aid measures must be carefully adjusted, and financial strategies must be fine-tuned to improve the overall efficiency of enterprises.

Managers of small businesses face the need to master strategic management skills, including the ability to deeply analyze both the internal and external business environment, find opportunities for development and sustainable progress. Small business should be considered an important component of the country's economic system, requiring development in harmony with national goals. Strategic management of small business has its own nuances and complexities, which is why there is a need to develop theoretical and methodological tools aimed at maintaining and strengthening the stability of this segment. This also involves the selection and adaptation of scientific and practical resources designed to ensure the successful functioning of small businesses.

In modern scientific literature, the issue of forming strategic directions for small business development has been touched upon relatively recently and is inspired by the experience of states with established market economies. The lack of a well-developed structure for supporting small business development at the regional level in modern Russia often leads to inconsistency in development strategies, undermining the potential for sustainable interaction with the country's economy as a whole.

IV. Discussion

In this regard, there is an urgent need for research aimed at establishing mechanisms for sustainable development in small businesses. This is understood as the ability to maintain positive, both qualitative and quantitative, changes in business activity, maintaining viability even under the influence of external changes (state of dynamic homeostasis), which in turn contributes to the economic growth of the Russian Federation, using available resources as efficiently as possible.

Structuring the sustainable development of small business involves the creation of a regulatory framework, the formation of conditions for activating entrepreneurial activity among the population, and the implementation of priority tasks to stimulate small and medium-sized businesses.

business, as well as the development of methods for assessing the current state and development prospects of enterprises in this sector. Sustainable development can be achieved through competent management and targeted forward movement of the system.

Important economic and social indicators for achieving sustainability in the sphere of small business are highlighted, including: formation of an optimal number of small business structures sufficient to create a critical mass; promotion of economic growth and encouragement of business initiatives; effective and efficient action aimed at fulfilling the set tasks and the most productive use of resources; improvement of the standard of living of both participants in the "small business" system and broader sections of the population.

Transformations in small business and strategic planning of its support pose multiple challenges due to its unique role in the economy. The lack of a comprehensive approach to supporting this sphere undermines the opportunities for sustainable economic development of regions. Therefore, it is important to improve and integrate theoretical and practical experience to create an effective model of sustainable development of small business in a specific area.

Given the importance of small businesses in creating jobs, maintaining competitiveness, and stimulating innovation, it is important to formulate a strategy that is oriented toward adapting to economic changes and challenges. This will allow resources to be used more consciously and ensure the long-term sustainability of small businesses, contributing to the overall economic well-being of regions.

Promoting sustainable development of small businesses requires a clear development of concepts and mechanisms for their implementation in practice, emphasizing the need for active actions to implement the established principles of sustainability. The key aspect here is the transition from a borrowing-oriented to a profitability model that brings positive effects to the whole society. This entails comprehensive state assistance, covering financial, property, insurance and credit support, as well as improving the information and legal framework. The need to improve legislation requires the development and implementation of such key bills as on small entrepreneurship, on investments and on insurance of small businesses, as well as on lending to small businesses.

$$\text{Sustainable development of small businesses} = \int_{t_0}^{t_1} (\alpha C(t) + \beta A(t) + \gamma S(t) + \delta L(t))\, dt$$

Where:

- $C(t)$ $A(t)$, $S(t)$, $L(t)$ are functions of time representing the dynamics of concepts, active actions, government support and legislative initiatives.
- α, β, γ, δ – weighting coefficients reflecting the importance of each factor for sustainable development.
- $\int_{t0}^{t1}$ −the integral over time from the initial moment t_0 to the final moment t_1, showing the accumulated effect of all factors on sustainable development over a given period of time.

This formula reflects the influence of various factors (concepts, actions, support, legislation) on the sustainable development of small businesses, taking into account their evolution over time. The integral emphasizes that business sustainability is a process that develops over time, and not a one-time phenomenon.

1.1. Resource efficiency index **(I_{res}):**

where P_{output} is the output of products (revenue, profit), P_{input} is the cost of resources.

$$I_{res} = \frac{P_{output}}{P_{input}}$$

1.2. Economic growth index (I_{growth}):

$$I_{growth} = \frac{B_t}{B_{t-1}} \times 100\%$$

This formula can be adapted and used to develop a method for assessing entrepreneurial activity at the regional level, taking into account the principles of sustainable development.

Each of the factors in the formula C(t),A(t),S(t),L(t) can be adapted to assess the specifics of regional entrepreneurial activity:

- C(t)— concepts and strategies of regional development. Each region may have its own characteristics that affect the sustainable development of small businesses (for example, access to natural resources, technological infrastructure, transport accessibility).
- A(t)— active actions of entrepreneurs in the region. This may include innovative projects, the number of new startups, and the dynamics of small business development.
- S(t)— regional support. This factor includes support measures provided by the regional government: subsidies, grants, tax breaks, and infrastructure projects.
- L(t)— regional legislative initiatives. Here, one can take into account the peculiarities of regional legislation aimed at developing entrepreneurial activity.

The recognition of the importance of small business as a driver of economic change has led to the desire to deepen the substantive-analytical understanding of its functioning and internal processes. Such analysis aims to activate entrepreneurial resources for the implementation of large-scale economic reforms. Strategically oriented management of small business should be aimed at strengthening the macroeconomic situation in the country and stimulating economic development in each region. Entrepreneurship existing at the local level significantly affects the socio-economic progress of the regions, their stable development is the cornerstone for the dynamic economic growth of the country.

Promoting sustainable development of small businesses requires a clear development of concepts and mechanisms for their implementation in practice, emphasizing the need for active actions to implement the established principles of sustainability. The key aspect here is the transition from a borrowing-oriented to a profitability model that brings positive effects to the whole society. This entails comprehensive state assistance, covering financial, property, insurance and credit support, as well as improving the information and legal framework. The need to improve legislation requires the development and implementation of such key bills as on small entrepreneurship, on investments and on insurance of small businesses, as well as on lending to small businesses.

In the context of reforming the Russian economy, new forms and methods of support are being sought, which increases the importance of government bodies at all levels and determines their role in the country's economic strategy. Assistance to small businesses consists of creating favorable conditions for the independence of citizens and providing support from the state, which will become the basis for sustainable economic growth. The tactics and strategy for developing entrepreneurship include developing government programs, providing investment financing, creating methodologies for assessing and supporting investment projects, and improving the tax system. Not only the success of individual entrepreneurs, but also the economic well-being of the country as a whole depends on these steps.

Modern small business management will call for innovative methods and the creation of a fundamentally new set of tools. Such tools, based on accurate diagnostics and differences in the operating conditions of small businesses in different regions, should allow for a separate assessment and improvement of the quality of financial management. An important element here will be specific indicators that will track and analyze business activity, profitability and solvency at the enterprise, as well as the possibility of comprehensive rating of enterprises taking into account their development and attractiveness for investment.

Within the framework of the strategy for sustainable growth of small business, special attention is paid to the economic liberalism of citizens, implying their active integration into the entrepreneurial sphere and strict assistance from government agencies. This is the path to consistent strengthening of the country's economic potential. The strategy involves the mobilization and adaptation of entrepreneurial abilities, the adoption of a balanced system of government support measures, the interaction of small and medium-sized businesses, as well as the expansion of foreign economic relations and the strengthening of the positions of small companies both locally and nationally.

The concept is based on a number of key principles:

- Initiative and creative activity of people in the business sphere, transforming material assets into profitable investments, instead of simple rent. This approach is aimed at creating social value and welfare.

- Develop a comprehensive strategy that involves small businesses interacting with the environment and directing limited resources where they can bring the greatest benefit to the regional economy.

- Application of reliable government incentive programs that are comprehensive in nature and take into account the unique features, economic conditions and potential changes in the development of business entities, regions and the country as a whole.

To implement this strategy for sustainable development of small businesses, it is essential to have effective tools to achieve the goals:

1. Develop a comprehensive government assistance program covering legal, financial and material assistance, which will include measures on registration, taxation, lending and protection.

2. Allocation of significant budgetary funds, their direction and monitoring of the effectiveness of investments for the benefit of small businesses, with subsequent assessment of the impact of these investments on the quality of life in the region.

3. Development and application of scientific methods for determining investment objects based on indicators of success and efficiency of working capital use.

4. Improving the legal and informational framework for providing access to economic resources, taking into account the need to focus them on priority tasks and strategic directions.

5. Using specialized approaches to planning and economic analysis, adapted to the unique conditions and characteristics of small business organization.

Abstract

This article delves into the intricate relationship between sustainable development and economic growth, highlighting the necessity of harmonizing environmental, social, and economic considerations to foster long-term prosperity. The study explores how sustainability-focused policies, such as promoting renewable energy, reducing carbon emissions, and enhancing social inclusion, can positively influence economic growth by increasing resource efficiency and driving innovation. It also addresses the complex trade-offs between immediate economic gains and the long-term benefits of sustainability, emphasizing the importance of aligning short-term policy goals with long-term environmental and social objectives. Through an analysis of key sustainability practices, including the adoption of green technologies, responsible resource management, and policies aimed at reducing inequality, the article demonstrates how sustainable development can mitigate the adverse effects of climate change, promote social justice, and create more resilient economies. The article draws on international case studies from countries leading in sustainable practices, providing insights into how governments, businesses, and communities can effectively balance economic development with environmental conservation and social well-being. Moreover, the paper highlights the growing role of global cooperation in sustainable development, underscoring how cross-border environmental impacts, financial markets, and technological innovation contribute to shaping the future of sustainable economic growth. The research argues that sustainable development is not only essential for safeguarding natural ecosystems and addressing social inequities but also crucial for ensuring long-term economic stability and competitiveness in a rapidly changing global landscape. By integrating sustainability principles into economic frameworks, nations can promote inclusive growth that benefits all segments of society while preserving the planet for future generations.

Keywords: climate change mitigation, social justice, inequality reduction, sustainable innovation, long-term economic stability, global cooperation, environmental conservation

I. Introduction

In recent decades, the concept of sustainable development has emerged as a critical framework for balancing economic growth with environmental protection and social inclusion. As global challenges such as climate change, resource depletion, and growing inequalities intensify, the traditional models of economic development that prioritize short-term gains over long-term sustainability are increasingly being questioned. Sustainable development, which integrates environmental, social, and economic dimensions, offers a more holistic approach to growth, ensuring that current needs are met without compromising the ability of future generations to meet theirs.

Economic growth has long been viewed as a primary driver of societal progress, leading to improved living standards, technological advancements, and job creation. However, unchecked growth can have severe environmental and social costs, including pollution, biodiversity loss, and widening wealth disparities. These consequences undermine the long-term stability of economies and exacerbate social tensions. Therefore, aligning economic growth strategies with sustainable development principles is essential to building resilient economies that can withstand future shocks while promoting social well-being and environmental stewardship.

This paper examines the impact of sustainable development on economic growth, exploring how policies that address environmental sustainability, social equity, and responsible resource management can foster long-term economic prosperity. The study also analyzes the potential trade-offs and synergies between economic growth and sustainability, offering insights into how nations can achieve balanced development. Through international examples, the research highlights best practices and innovative approaches that demonstrate the feasibility of achieving economic growth without sacrificing ecological health or social fairness. By fostering a green economy, promoting renewable energy, and encouraging inclusive social policies, sustainable development can serve as a pathway to a more stable, equitable, and prosperous global future.

II. Methods

This study employs a combination of qualitative and quantitative research methods to explore the impact of sustainable development on economic growth, focusing on the interplay between environmental, social, and economic factors. The methodological approach is designed to provide a comprehensive understanding of how sustainable policies influence economic outcomes and to identify best practices for balancing growth with sustainability.

1. Literature Review

A thorough review of existing academic literature, policy reports, and case studies is conducted to establish a foundation for understanding the theoretical and practical links between sustainable development and economic growth. The literature review covers various aspects, including environmental economics, green technologies, social inclusion, and sustainable policy frameworks. This provides context for the analysis and highlights the key challenges and opportunities associated with sustainable growth.

2. Comparative Case Studies

The study analyzes several international case studies from countries with leading practices in sustainable development, such as the European Union, the United States, and emerging economies like China and Malaysia. By comparing these cases, the research identifies the different approaches countries take to integrate sustainability into their economic growth strategies. The selection of case studies is based on the diversity of their policy frameworks, economic structures, and environmental challenges.

3.Quantitative Data Analysis

To assess the economic impact of sustainable development, statistical data on key economic indicators such as GDP growth, employment rates, and investment flows are analyzed in conjunction with sustainability metrics like carbon emissions, renewable energy adoption rates, and social equity measures. Data is sourced from reliable international databases, including the World Bank, OECD, and the United Nations. This quantitative analysis helps to identify correlations between sustainable development policies and long-term economic performance.

4. Policy Analysis

The study also conducts an in-depth analysis of sustainability-oriented policies, such as tax incentives for green technologies, environmental regulations, and social welfare programs. The focus is on understanding how these policies are designed and implemented to promote economic growth while minimizing environmental degradation and social inequality. Specific policies like carbon pricing, green bonds, and renewable energy subsidies are examined to evaluate their effectiveness in driving sustainable economic outcomes.

5. Expert Interviews

Interviews with experts in the fields of environmental economics, sustainable finance, and public policy are conducted to gain qualitative insights into the practical challenges and opportunities of implementing sustainable development strategies. These interviews provide valuable perspectives on the real-world impacts of sustainability initiatives on economic growth, as well as the barriers to their success.

6. Sustainability Index Analysis

Lastly, the study utilizes global sustainability indexes, such as the Sustainable Development Goals (SDGs) index and the Environmental Performance Index (EPI), to measure the progress of countries in achieving sustainable development. These indexes are cross-referenced with economic growth data to determine the effectiveness of various sustainability efforts in driving economic development.

By employing a mixed-methods approach, the study provides a robust analysis of the relationship between sustainable development and economic growth, offering both theoretical insights and practical recommendations for policymakers.

III. Results

Sustainable development has become a central concept in addressing the growing global challenges of environmental degradation, social inequality, and economic instability. The most widely accepted definition comes from the Brundtland Report, which describes sustainable development as growth that meets the needs of the present without compromising the ability of future generations to meet their own needs (Brundtland Report, 1987). This concept embodies the balance between satisfying current societal expectations and protecting the long-term viability of our environment, economy, and social structures. Magis (2010) further emphasizes that sustainable development promotes individual well-being, fosters social cohesion and inclusion, and creates equal opportunities for all people, both now and in the future.

1. Sustainable Development and Food Security

In the context of agriculture and food production, sustainable development involves ensuring food security through the consistent and resilient production of food. Food security, a key pillar of sustainable agriculture, requires continuous monitoring and the implementation of policies aimed at protecting vulnerable farmers, pastoralists, and landless individuals. Agricultural reforms and incentives can help improve the production and distribution of food while safeguarding the interests of those most affected by food insecurity. These policies focus on creating systems that can withstand shocks such as climate change or economic disruptions, ensuring the global food supply remains robust.

2. Species and Ecosystems

From an environmental perspective, species and ecosystems represent essential natural resources that must be preserved for ongoing development. Sustainable development emphasizes the protection of biodiversity, including both living organisms (such as plants, animals, and microorganisms) and the non-living components of ecosystems that they rely on. The degradation of natural habitats and loss of biodiversity pose significant risks to agricultural productivity and ecosystem services, which are critical for human survival. Sustainable management of these resources ensures that development does not come at the cost of irreversible environmental damage, allowing future generations to benefit from the same resources.

3. Energy and Power

Energy is a fundamental component of development, particularly in agriculture, where it is necessary for powering machinery, irrigation, and transportation. The challenge lies in ensuring that energy sources are sustainable, reliable, and environmentally friendly. Today's energy demands are met through a variety of means, but the reliance on non-renewable resources such as fossil fuels has significant environmental consequences, including greenhouse gas emissions and pollution. Sustainable development encourages the transition to renewable energy sources that can support long-term agricultural productivity without harming the environment. Energy security is critical for maintaining the growth and resilience of agricultural systems, particularly in regions that are heavily dependent on energy for production.

These three elements—food security, species and ecosystems, and energy—are interrelated and form a nexus often referred to as the "water-energy-food nexus" (Borowski, 2020; Purwanto et al., 2021). This nexus highlights the complex interactions between these systems and emphasizes the need for integrated approaches to managing them. As shown in various studies, achieving sustainability in one area, such as increasing food production, can have negative consequences for others, such as depleting water resources or reducing biodiversity (Kasem & Thapa, 2012). Therefore, a holistic approach is necessary to ensure that agricultural practices contribute to overall sustainable development.

4. Agricultural Reforms and Productivity

In recent years, detailed research in both micro and macroeconomics has provided insights into how agrarian policies can promote sustainable growth. These studies reveal that while significant achievements have been made in boosting food production, much of this progress has come at the cost of environmental degradation and the depletion of natural resources. Intensive agricultural practices, such as monocropping and overuse of chemical inputs, have damaged ecosystems to the extent that some resources may be irretrievable for future agricultural use. A shift from destructive economic practices toward sustainable development is essential for ensuring long-term agricultural productivity.

Improving agricultural productivity is particularly crucial for addressing food insecurity in regions like Africa, where the agricultural sector plays a pivotal role in the economy and livelihood of millions (Pretty, Morison & Hine, 2003). Africa's agricultural productivity, though on the rise, still lags behind the global average. Initiatives to enhance private and public investments in agriculture, coupled with sustainable development policies, can help boost productivity, reduce food insecurity, and improve the resilience of agricultural systems in Africa.

IV. Discussion

Energy is fundamental to sustaining life and serves as the driving force behind economic development, industrial growth, and societal well-being. In today's world, various energy sources—such as fossil fuels, renewable energy, and even human and animal power—are critical for generating and transmitting the electricity necessary for daily life. As economies expand and energy demand grows, ensuring the availability of reliable, safe, and environmentally friendly energy sources for all is a significant challenge.

One of the most pressing issues of the 21st century is the gap between growing energy demands and the limited supply of conventional energy sources, which are predominantly nonrenewable. These sources, including oil, natural gas, coal, and nuclear power, are finite and environmentally detrimental. However, there is a growing shift towards renewable energy, such as solar, wind, hydropower, biomass, and geothermal energy, which offer nearly unlimited potential and are more sustainable (Shao, 2020). The transition to renewable energy is crucial for maintaining ecosystem balance while meeting the needs of an ever-growing population.

Economic development, urbanization, and increased industrial activity have driven energy consumption to unprecedented levels, especially in developed nations, leading to a global imbalance in energy resource distribution. Despite improvements in energy efficiency, total energy consumption continues to rise. This growing demand exacerbates environmental challenges, particularly in developing countries, where inadequate management of renewable energy systems and infrastructure poses significant social and environmental risks.

For example, the use of wood for cooking in rural areas can result in severe health issues, such as respiratory and eye diseases, due to smoke and harmful emissions. Similarly, emissions from the combustion of agricultural residues and exhaust from machinery contribute to air pollution. Poorly managed renewable energy systems, including the burning of biofuels and improper disposal of organic waste, can also lead to water and soil contamination, negatively impacting both human health and the environment.

These challenges illustrate that while renewable energy offers a path to sustainability, its production and implementation must be carefully managed to avoid unintended consequences. Agriculture, as a major consumer of energy, plays a crucial role in this transition. By adopting sustainable practices and integrating renewable energy systems, the agricultural sector can help mitigate the environmental impacts of energy consumption and contribute to global sustainability goals.

A clean environment is essential for ensuring human health and well-being, yet the relationship between environmental factors and the health of humans and other species is complex and multifaceted. The preservation and sustainable management of natural resources is a critical development issue, as adverse changes in the environment can surpass the adaptive capacities of organisms, reducing the survival chances of many species, including humans. One of the most pressing challenges is understanding the key factors driving species extinction and ecosystem degradation, particularly how government policies on natural resources contribute to these trends.

Climate change exacerbates this problem, leading to increased public expenses as governments compensate for damages from environmental disasters, such as those affecting private households and state infrastructure. Given these escalating costs, there is a growing need for governments to adopt new approaches and create innovative models for sustainable management. However, the intricate relationship between fundamental and applied sciences in sustainable development complicates this task. State institutions, even in developed countries, must play a more proactive role in research and development efforts aimed at sustainability.

The human body has adaptive mechanisms that can often cope with harmful environmental factors, but when these stressors become chronic or severe, the body's capacity to adapt is overwhelmed, leading to both physical and mental health issues. This highlights the urgency for governments to reassess their policies in sectors such as agriculture and forestry. They must ensure that both the environment and the population are protected from harmful impacts while contributing to national development goals.

A major challenge for most governments is the limited availability of resources dedicated to environmental conservation. The critical question is not only how to secure more resources but how to use existing ones most efficiently to achieve conservation priorities. Governments must balance immediate needs with long-term sustainability, ensuring that their actions promote health, protect ecosystems, and foster development for future generations.

Abstract

The objective of this article is to identify and substantiate new approaches to the management of national parks (NP) under the current conditions of increasing risks. The study demonstrates that in order to preserve ecological capacity and valuable natural heritage, the primary trend in management is shifting towards risk management, particularly concerning climate change and increasing recreational pressures, which adversely affect ecosystem viability. The research conducted in 2023 focused on the territory of the "Curonian Spit" National Park and the adjacent coastal areas of the Curonian Lagoon on the southeastern coast of the Baltic Sea.

The study reveals that in a risk-prone external environment, national park management should be oriented towards ensuring strong sustainability through the use of a Sustainable Ecosystem Design (SED-NP) mechanism. This approach offers a systematic vision, flexible and pragmatic solutions, and methods that help to coordinate disparate efforts in sustainable tourism and biodiversity conservation with the aim of preserving the integrity of ecosystems and their capacity to generate ecosystem services in the face of external threats. The application of SED-NP approaches allows for the integration of data on ecosystem services, depletion/degradation and replenishment/restoration of ecosystems, benefits (income and advantages), and other characteristics into the NP management system.

The research justifies the conclusion that the studied territory – a narrow strip of land washed by the waters of the Baltic Sea and the freshwater Curonian Lagoon – is, due to historical circumstances, a product of the local population's climate and natural risk-reflection. The local population ensured their survival and well-being through continuous and deliberate protective actions to reinforce the spit and preserve the Curonian Lagoon, which sustained them. The analysis of the territory's condition identified two primary groups of risks to ecosystem viability and biodiversity: climate-related risks and recreational pressures, which require focused attention. The spatial localization of areas within the "Curonian Spit" National Park most susceptible to climate risks and recreational degradation was determined. A set of measures was developed to mitigate recreational degradation and climate risks. An ecological, social, and economic assessment of the effectiveness of measures to reduce risks to the ecosystem viability of the Curonian Spit was conducted in monetary terms. A mechanism for the ecological, social, and economic justification of decisions regarding *the development of the territory from the perspective of strong sustainability and reducing risks to ecosystem viability and loss of ecosystem services was developed and tested.*

New approaches to managing national parks under the current conditions of increasing risks were developed, which are implemented through a system of restrictions and regulations. The application of a decision-making justification mechanism for NP development, in accordance with the principle of strong sustainability, ensures qualitative control of tourist flows in time and space, the creation of zones for various types of tourism use, and the planning of necessary infrastructure adapted to individual needs, including those beyond the boundaries of specially protected natural areas.

Keywords: sustainability, national park, management, climate risks, tourism, natural capital, ecosystem services, recreational degradation

I. Introduction

In today's world, profound changes in ecosystems are happening in no time, accompanied by a decline in the ecosystem services provided to humans. According to the "Millennium Ecosystem Assessment" (2005), more than 60% of ecosystem services are currently degrading or transforming. The main factors exacerbating the crisis of protected natural areas (PNA) worldwide include: (1) increasing climate risks and their negative impact on biodiversity; (2) growing demand for nature-based recreation in increasingly urbanized societies; and (3) the destruction of relatively untouched natural habitats, transforming into other forms of land use as population grows, wealth increases, and more natural resources are used.

One of the primary contemporary challenges in the development of PNA is to achieve a sustainable balance between tourism development and the necessity of preserving valuable natural and cultural heritage under conditions of increasing climate and anthropogenic risks. According to the World Charter for Sustainable Tourism (UN, 1995), management of all resources in such a way that economic, social and aesthetic needs can be fulfilled while maintaining cultural integrity, essential ecological processes, biological diversity and life support systems[1]. In Russia, the sustainable development of PNA and the creation of conditions for ecotourism in national parks are considered a key priority for achieving the national goal of "Ecological Well-being" (Clause 5) at the highest state level[2]. In the current context of high risks and uncertainties, national parks[3] represent the most effective form of territorial management aimed at preserving the social and economic significance of the ecosystem services provided by nature.

Many national parks have been established worldwide for the protection of nature. As of the end of 2022, Russia had 67 national parks of federal significance, alongside reserves, with a total area of 31.4 million hectares. However, as Fortin and Gagnon (1999) correctly pointed out, these parks were often created without adequate analysis of the consequences for neighboring communities [1]. Giving unique territories the status of a national park, in addition to strengthening nature conservation, leads to unexpected consequences. Protected scenic landscapes have become magnets attracting not only visitors but also numerous investors. This increases the risk of losing the integrity of natural ecosystems and biodiversity due to recreational degradation

[1] Adopted by the World Tourism Organization (UNWTO), the World Travel and Tourism Council (WTTC) and the Earth Council in 1995.

[2] Decree of the President of the Russian Federation of 07.05.2024 No. 309 "On the national development goals of the Russian Federation for the period up to 2030 and for the perspective up to 2036".

[3] According to the 2013 Guidelines of the International Union for Conservation of Nature, "national parks" refer to "large areas of natural or near-natural areas designed to protect large-scale ecological processes and associated ecosystem species and characteristics.

[2], and heightens the vulnerability of ecosystems to destructive climate impacts.

Our studies in the "Curonian Spit" NP and the adjacent coastal areas of the Curonian Lagoon in the Kaliningrad region on the Baltic Sea have shown that addressing this complex set of problems requires the application of risk-oriented management approaches when justifying decisions on the development of the NP territory and its buffer zone, as well as when refining visitor flow restrictions and regulations. For this, the traditionally collected data on the condition and trends of ecosystem and natural object changes, and visitor flow numbers are insufficient. This underscores the high relevance and practical significance of developing new approaches to NP management under modern conditions of increasing climate risks.

II. Methods and Data

In recent decades, the number of studies on the risks of decreasing ecosystem resilience under increasing external threats has grown. Not only ecological but also socio-economic impacts on national parks have been described [3], as well as the associated losses and benefits [4]. In the context of sustainable development, the view that national parks should be considered as investments in public goods has gained traction. De Groot et al. (2012) conducted the first global assessments of a range of ecosystems and services, including for coastal systems [5]. The multi-faceted consideration of the economic value of national parks has been reflected in the works of many scientists and specialists (R. Constanza, M. Wilson, S.N. Bobylev, G.A. Fomenko, R.A. Perelet, V.M. Zakharov, and others).

Numerous studies have also focused on sustainable tourism development [6-10]. To date, there is consensus on several fundamental issues related to the dependence of NP sustainability on stakeholder interactions, particularly the constructive interaction between NP management and local communities [11-17]. NPs should not be viewed as isolated natural ecosystems requiring unconditional protection, but rather as particularly complex anthropo-natural systems (ANS) that constitute a significant portion of a nation's and region's wealth due to their high proportion of non-depleting natural capital.

To effectively address these challenges, two fundamental aspects should be focused on: (1) ensuring, as much as possible, the resilience of ecosystems in the face of increasing destructive climate impacts; and (2) preventing the destruction and loss of ecosystems due to anthropogenic pressures in the form of increasing visitor numbers and changes in ecosystem use on adjacent lands, the buffer zone, and the NP territory itself by altering conservation status. Actions should be based on sustainable development principles, considering the interests of a wide range of stakeholders and conducting an analysis of the state of ecosystems and the flows of ecosystem services in the protected area and adjacent lands.

The task set in Russia to orient NPs towards sustainable development and create conditions for ecotourism[4] cannot be achieved through technical means alone. Significant adjustments to approaches to planning and spatial development design of protected areas are needed, following the inviolable ethics of Life, which recognizes the intrinsic value of all living things and strives to preserve it in an unstable external environment. Scientific discourse in this aspect is conducted in the context of moving sustainable development methodology towards a goal-oriented synthesis of natural, cultural, and socio-economic values, along with the corresponding system of restrictions and regulations on economic activities [18].

This vision is being implemented in NPs through the methodology of Sustainable Ecosystem Design (SED), which we are developing [19-21], considered as a special type of relationship with the high-risk and uncertain reality. The essence of SED in the context of NPs lies in an ethically-oriented, goal-rational, systematic approach to planning the development of national parks that reduces the likelihood of ecosystem destruction and the loss of natural wealth. The main focus is

[4] Decree of the President of the Russian Federation dated 07.05.2024 No. 309 "On the national development goals of the Russian Federation for the period up to 2030 and for the perspective up to 2036".

on minimizing risks through coordinated actions for biodiversity conservation in conjunction with climate adaptation[5]. A justified system of restrictions is applied based on special zoning of the territory, along with the verification of land-use decisions regarding NP development in accordance with the principles of sustainable development.

In the course of research we used: (1) materials of functional zoning of the territory of NP "Curonian Spit", information about the boundaries, areas and types of land cover of functional zones, information about the location, length and arrangement of eco-trails and tourist routes; (2) data on quantitative, spatial, temporal and cost characteristics of the flow of visitors, environmental constraints, the stability of the territory of the Curonian Spit to recreational loads; (3) information about existing and planned recreational facilities; about planned works on territory improvement; (4) information about economic entities providing services on the territory of the NP; (5) information about volumes of recreational fishing within the boundaries of the park's protection zone in the Curonian Lagoon and on the Baltic coast, about volumes of non-timber forest resources (mushrooms and berries) harvested by the local population and visitors; (6) information about prices for fish, mushrooms and berries in the markets of Zelenogradsk and Kaliningrad; (7) historical information about the Curonian Spit region.

III. Results

The research was conducted in the "Curonian Spit" National Park (NP) and on the coastal areas of the Curonian Lagoon in the Kaliningrad region, located in the southeastern Baltic region (see Figure 1).

Figure 1: *Situational map-scheme of the "Curonian Spit" NP location*

This coastal area, inhabited by humans for many centuries, is a product of the local population's climate and natural risk-reflection, ensuring their livelihood through thoughtful actions to protect the Curonian Lagoon, which provided their sustenance.

[5] Adapting to climate change means planning for and acting on the expected impacts of climate change. It involves making changes to how we live and what we do before the impacts of climate change occur (anticipatory action), and being prepared to respond to increasingly likely and frequent extreme events (response).

The unique character of the Curonian Spit is the result of various peoples' efforts to preserve it for future generations. The Curonian Spit represents a rare and successful example of the history of coexistence between nature and humans, with an abundance of both natural and cultural assets[6]. It is a unique cultural landscape with a system of protective engineering structures and forest plantations, formed and developed through the interaction of the sea, wind, and human activity. This is an example of the continuous process of self-development of a Living system, within which the activities of the "Curonian Spit" NP are integrated. To preserve the typical coastal communities of the Southeastern Baltic and the unique natural complexes of the Curonian Spit, as well as to protect spawning and nursery areas for commercially valuable fish species, marine mammals, and birds during migrations and breeding from adverse anthropogenic impacts, a protective zone of the national park has been established[7].

An analysis of spatial data from the "Curonian Spit" NP for the period 1991-2021 revealed that the ecosystems as a whole have undergone some changes (see Table 1).

Table 1: *Ecosystem change characteristics in the "Curonian Spit" NP for 1991-2021*

Ecosystems	Factors of Ecosystem Change		Quantitative Change (ha)	Comments on Causes of Change
	Anthropogenic	Climatic		
Forest	↑	–	954	Encroachment of forest on meadow ecosystems due to natural (development of fertile soil layer, natural afforestation, etc.) and anthropogenic processes (reforestation activities by the national park, adherence to restrictions on visiting certain particularly valuable areas)
Meadow	↓	–	-882	Sand movement due to wind, afforestation
Coastal (dunes and beaches)	↘	–	-82	Encroachment of grassy vegetation, including as a result of protective measures
Freshwater Internal (lakes and swamps)	–	–	0	–
Marine (Baltic Sea)	↗	↗	46	Shoreline erosion due to increased storm activity
Freshwater External (Curonian Lagoon)	↘	↘	-71	Expansion of dunes toward the lagoon due to intensified winds
Settlements	↑	–	35	Expansion of built-up area

The data in Table 1 indicate that the most significant changes in ecosystem areas occurred in forest (increase) and meadow (decrease) ecosystems. However, given the importance of stabilizing the sandy body of the Curonian Spit with forest plantations to preserve ecosystem services for beach recreation, these changes do not increase the risk of territorial degradation (reduction in natural capital), but rather contribute to its reduction. Climatic changes, such as the increased frequency of storm events in the southeastern Baltic and wind pressure on coastal areas from the Curonian Lagoon [22], have led to a decrease of the Curonian Spit's landmass by 46 hectares on

[6] The territory of the Kurshskaya Spit NP was included in the UNESCO World Heritage List in 2000 as part of the international Russian-Lithuanian site "Curonian Spit". URL: https://whc.unesco.org/ru/list/994. Date of reference: 12.03.2024.

[7] Order of the Ministry of Natural Resources of Russia No. 306 of 27.04.2022 "On establishing the boundaries of the protection zone of the Kurshskaya Spit National Park along the border with the Baltic Sea water area, as well as on approval of the Regulations on this protection zone".

the sea side and 71 hectares on the lagoon side. Retrospectively, the condition and characteristics of ecosystem assets (natural capital) fluctuated within acceptable levels, maintaining the potential to generate ecosystem services during the specified period and up to the present day.

The main climatic and anthropogenic vulnerabilities of the Curonian Spit's ecosystems and the coastal areas of the Curonian Lagoon. They include the increased frequency of storms, which damage economic and infrastructure facilities due to periodic breaches of the spit (when Baltic saltwater breaks into the freshwater Curonian Lagoon), and negatively impact biodiversity by disrupting ecosystem conditions. Another significant threat is the increase in the annual flow of tourists to the "Curonian Spit" NP, which rose from 200,000 visits in 2010 to 809,415 visits in 2021, more than fourfold[8]. This has substantially increased the threat of ecosystem degradation on the Curonian Spit, loss of biodiversity, and deterioration of the ecological integrity of the area.

In the "Curonian Spit" NP, its protective zone, and the coastal areas of the Curonian Lagoon, opportunities, methods, and means of organizing the activities of the "Curonian Spit" NP were explored using the Sustainable Ecosystem Design (SED) mechanism, with the aim of aligning current management practices with the task of preserving particularly valuable natural complexes of biodiversity and quality of life for people.

From this perspective, several conclusions were drawn that are important for reducing the risks of ecosystem integrity disruption on the Curonian Spit, the Curonian Lagoon, and its coastal areas, and for maintaining ecosystem service flows.

First, two main groups of risks were identified – climate and recreational – which require primary attention for mitigation. Climate risks are associated with changes in temperature regimes[9], precipitation patterns[10], increased storm frequency[11], and other factors. Recreational risks are linked to the growing number of visitors, recreational degradation, loss of habitats, and invasive species aggression.

Second, the spatial localization of areas within the "Curonian Spit" NP most susceptible to climatic risks and recreational degradation was determined. The areas identified as most vulnerable to climate (intensified storm events and wind pressure) and recreational (increasing tourist flow) impacts include:

- Areas of greatest vulnerability to tourist and natural-climatic impacts (foredunes, dune ridges, flat areas with pine forest plantations);
- Areas of concern for biodiversity (critical habitats for populations, locations of rare plant species, etc.).

Third, a comprehensive set of measures was developed to mitigate the risks of recreational degradation and climatic impacts. As part of the recreational activities plan of the "Curonian Spit" NP, a comprehensive set of measures was designed to reduce recreational degradation and climatic risks, including:

- Reducing recreational degradation risks, which involves (1) refining the zoning of the "Curonian Spit" NP to more fully encompass restrictions and prohibitions on visiting areas most vulnerable to recreational impacts and valuable for biodiversity conservation (foredunes, dune ridges, flat areas with pine forest plantations, critical habitats for populations, locations of rare plants, etc.); (2) constructing recreational infrastructure to prevent negative impacts from tourist flows on ecosystems (arranging parking lots,

[8] Information report of the FGBU "Kurshskaya Spit National Park" for 2021.

[9] Climate warming is felt in the Kaliningrad region, first of all, due to the increase in surface air temperature: for Kaliningrad - over a long period (168 years) at a rate of 0.01 °C per year, and for some other settlements of the region (Baltiysk, Sovetsk, Zheleznodorozhny) and Kaliningrad together - over a shortened period (56 years) at a rate of 0.03 °C per year [23].

[10] Average annual precipitation has been increasing by 4 mm every 10 years for the last 60 years; during the period of greatest warming (1980-2018), the rate of increase in precipitation has especially increased in July, with July precipitation increasing by 12.53 mm every 10 years; in the last 10 years, anomalous rainstorms have been occurring annually, with one or two days of monthly precipitation [24].

[11] Between 1966 and 1985, there was an average of 26 storm events per year; between 2004 and 2014, there were 254 storms, with an average of 28 storms per year; the number of days with high winds (>15 m/s) increased annually by 0.7 days and the average annual wind speed by 0.1 m/s [24].

sanitation sites, waste collection, and removal points).

- Reducing climatic risks, including constructing pathways across the foredune, reinforcing the foredune body, planting trees on dunes, and building shoreline protection structures in coastal areas most vulnerable to storm and surge impacts (foredunes, beach areas on the sea side).

Fourth, an ecological-social-economic justification mechanism for decision-making in the field of preserving natural complexes, unique and reference natural sites, and reducing the risks of their degradation was developed and tested. This mechanism is aimed at evaluating the ecological-social-economic consequences of various projects or specific intentions, documented as decisions that could be implemented in the "Curonian Spit" NP. The mechanism is based on the principle of "result-based management," widely used in public administration as an adequate and transparent method for assessing the implementation of state programs, mainly of a humanitarian nature, where purely financial assessment mechanisms have very limited use.

The developed mechanism is formulated as a sequence of actions, the results of which complement standard environmental impact assessment (EIA) procedures. The outcome provides comparable quantitative assessment indicators of the evaluated project's/program's/investment intention's impact on ecosystems, social and economic spheres, and summarizes these assessment data for compliance with the principles of strong sustainability.

The assessment is conducted using three evaluative characteristics: impact on (1) ecosystems, (2) the social sphere, and (3) the economic sphere. Each of the evaluative characteristics is specified by a group of corresponding assessment indicators (see Table 2). During the assessment, the projected state data (project line), expected as a result of the project's/intention's implementation, is compared with the baseline state (baseline) of the territory, without the project but under the influence of existing change factors (in our case, climatic and anthropogenic).

Table 2: *Evaluative Characteristics and Indicators for Assessing the Socio-Economic Significance of the Project*

No.	Evaluative Characteristics	Assessment Indicators
1	Impact on Ecosystems	1.1 Total area of ecosystems not significantly transformed by anthropogenic activity, ha
		1.2 Anthropogenic transformation coefficient of ecosystems, %
		1.3 Threat of anthropogenic degradation of ecosystem areas and objects, points
		1.4 Recreational load on the territory, person-days/day
		1.5 Maximum allowable recreational capacity of the territory, persons/day
2	Impact on Social Sphere	2.1 Approximate number of users of ecosystem services in the territory, broken down by types of ecosystem services, persons/year
		2.2 Number of visitors to the territory, including people with limited physical abilities, persons/year
		2.3 Number and list of main beneficiaries of ecosystem services in the territory, units/year
		2.4 Employment provided by ecosystem services in the territory, including for people with disabilities and local residents, persons/year
3	Impact on Economic Sphere	3.1 Potential gross income from the provision of ecosystem services, RUB/year
		3.2 Potential gross income from the provision of ecosystem services related to the tourism industry, RUB/year
		3.3 Approximate tax revenues to the budgets of all levels from the provision of ecosystem services and their use, RUB/year

Positive results were obtained from testing the Mechanism for Assessing the Compliance of Actions for the Development of the Curonian Spit National Park (NP) with the Principle of Strong Sustainability when developing activities for the recreational plan of the Curonian Spit NP. The assessment of activities showed that the projects with the highest ecological, social, and economic significance include the construction of pathways across the foredune near the tourist base (by reducing the risk of foredune destruction and degradation of the adjacent coastal ecosystems), the creation of a parking area at the park entrance (by reducing the risks of uncontrolled use of the territory by visitors), and the establishment of recreational routes in areas adjacent to the NP, which helps to reduce the recreational load on the protected areas of the Curonian Spit and significantly lowers the risks of recreational degradation.

The results confirmed the effectiveness of the proposed Mechanism in the development of programs and plans for the national park's territory, in decision-making regarding land use, and in reducing the risks of ecosystem degradation and loss of ecosystem services.

Fifth, an ecological, social, and economic assessment of the effectiveness of measures to reduce the risks to the viability of the Curonian Spit ecosystems was carried out in monetary terms. The viability of ecosystems is determined by the flow of ecosystem services they provide, its sustainable nature, and its value in ecological, social, and economic terms. From an economic efficiency standpoint, this value is expressed in monetary terms. In the case of the Curonian Spit, the key role in maintaining its integrity – and therefore the state and properties of ecosystems and the value of ecosystem services – is played by the activities of the Curonian Spit NP.

Thus, the effectiveness of measures to reduce climate and recreational risks was assessed based on the value of the existing flows of ecosystem services, which are largely ensured by the continuous efforts of the Curonian Spit NP to mitigate risks to ecosystems from climate and anthropogenic factors. The total value of ecosystem services in the Curonian Spit and the surrounding coastal and lagoon waters was estimated at 222.4 million rubles per year. The highest value is attributed to cultural ecosystem services for excursions and beach recreation – 71.3 and 72.8 million rubles per year, respectively; provisioning ecosystem services related to commercial fishing have a slightly lower value – 59.1 million rubles per year; the values of other provisioning services (amateur and sport fishing, mushroom and berry gathering, hay and wood harvesting), as well as regulating services (CO_2 absorption by the Curonian Spit ecosystems), range from 0.5 to 6.6 million rubles per year.

Additionally, the results of the ecosystem services assessment also reflect the contribution of the Curonian Spit ecosystems to the resilience capital of the region and the Russian Federation as a whole.

IV. Discussion and Conclusions

The study of potential directions for implementing the Curonian Spit National Park (NP) ecosystem services assessment (ESA) methodology to reduce climate and anthropogenic risks in the Curonian Spit and Curonian Lagoon has led to several important generalizations and conclusions.

Theoretical Considerations: In the face of increasing climate and recreational pressures, overcoming negative trends in regions that are attractive from a natural environment standpoint has shown that tourism management must be holistic. It must satisfy economic, social, and aesthetic needs while preserving cultural integrity, essential ecological processes, biodiversity, and life-support systems. This work should be based on the principles of the Charter for Sustainable Tourism, adapted to the geographical conditions of each region in the country.

It is essential to measure the impact of various human activities on protected ecosystems. Measuring the sustainability of a national park is the foundation of its management. However, monitoring the processes and phenomena occurring within the territory remains a significant challenge due to outdated approaches to measuring economic activity efficiency. The application of System of Environmental-Economic Accounting (SEEA) [12] can address this problem by

[12] Statistical Standard Central Framework of the System of Environmental Economic Accounting 2012 (System of Environmental Economic Accounting 2012 - Central Framework), in official translation 2017. URL: https://seea.un.org/sites/seea.un.org/files/seea_cf_final_ru_0.pdf Date of reference 12.07.2024

providing a comprehensive approach that aligns with existing data from state statistics and government funding structures. A key advantage of SEEA is its ability to understand the relationships between territorial development activities and the state of ecosystems through the flow of ecosystem services.

Managing the development of all forms of sustainable tourism in areas of high ecological value should primarily be based on the proper organization and control of tourist flows over time and space, the creation of zones for different types of tourism use, and the planning of necessary infrastructure. This infrastructure must support the viability of ecosystems and the flow of ecosystem services while being adapted to individual needs. Significant potential in this direction lies in the development of educational tourism in areas adjacent to the NP, with the possibility of integrating them into a single cluster. This approach allows for the diversification of tourist flows and reduces the risks of recreational degradation in protected areas.

For comprehensive analysis and comparative evaluation of potential directions and targets for the development of recreational flows, the results-oriented management[13] method and the Rapid Impact Assessment Matrix (RIAM) have proven highly effective. In our view, using this method in various geographical contexts will allow for determining the depth of analysis needed at different stages of spatial planning. This will provide government authorities, investors, and all stakeholders with timely and reliable information about the feasibility and priority of utilizing natural and cultural heritage sites in developing recreational flows.

Practical Considerations: A set of specific measures has been identified to reduce climate and anthropogenic risks to ecosystem viability and maintain ecosystem service flows. These measures include, first and foremost, refining the zoning of protected areas by identifying the most vulnerable sections to climate and anthropogenic impacts, with mandatory actions to mitigate these impacts (such as restrictions and access limitations, protective measures, etc.). In terms of preventing and avoiding future risks, the environmental, social, and economic justification mechanism for proposed projects, in addition to Environmental Impact Assessments (EIA), has proven effective. Additionally, it is important to develop tourism activities in areas adjacent to the national park.

In terms of monitoring, additional characteristics are important to reflect new risks and vulnerabilities, showing which actual services and in what quantities may be lost. The growing importance of sustainable monitoring of ecosystems in protected areas must be noted, as it forms the basis for creating ecological, economic, and social value through information and knowledge for public benefit. Monitoring should include not only the state and observed trends of ecosystems but also tourist flows. Moreover, accounting for the socio-economic conditions of the population living around the NP is increasingly recognized as essential for achieving ecosystem protection goals, as it facilitates constructive interaction between the NP and local communities.

Abstract

The article explores and substantiates the theoretical and methodological foundations of the environmental component of resource conservation management of agricultural enterprises in the context of ensuring sustainable development. The main directions of the negative impact of the activities of agricultural enterprises on the environment are identified, including: land depletion and loss of soil fertility, soil erosion, soil compaction, loss of biodiversity, groundwater pollution. Indicators characterizing the environmental efficiency of resource conservation management of agricultural enterprises have been determined. It is noted that the culture of resource conservation should become a mandatory element of the general culture of behavior of employees of agricultural enterprises. The article defines the main stages of the formation of organizational culture at an agro-industrial complex enterprise, which contains a component of resource saving.

Keywords: agriculture, ecology, efficiency, management, resource conservation, sustainable development

I. Introduction

Agriculture is one of the largest economic sectors in the world. Farmland and grassland make up about 50% of the Earth's habitable environment and provide habitat and food for large numbers of people. Today, for most modern agricultural enterprises, it is relevant to identify areas of economic and management activity that will help to effectively use natural resources in the same way that a reasonable approach will help preserve and restore the habitat, protect and improve the quality of soil and water. In addition, the agro-industrial complex is the basis for the formation of food security of the state and has a significant impact on the state of the country's economy. In addition to providing enterprises and the population with raw materials and food, the agro-industrial complex provides employment opportunities for a significant part of the population. Thus, according to 2022 data, about 4 million people are employed in agriculture in the Russian Federation [5].

In the international arena, our country is positioned as an agrarian state. Over the past decade there has been a significant increase in agricultural production. At the same time, not all agricultural enterprises understand the importance of using resource-saving technologies and apply the principles of sustainable development in their activities. The current stage of development is characterized by an intensification of anthropogenic impacts on the environment, since the widespread use of new technologies in the activities of agricultural enterprises accelerates the need to meet the needs of the population for various types of resources and raises the issue of their conservation.

Considering the exceptional importance and priority of agriculture for the national economy, the issue of increasing the effectiveness of development of the agro-industrial sector of the domestic economy has always occupied a central place in the scientific works of domestic scientists. Scientists studied the directions and mechanisms for ensuring the efficiency of agricultural production and development of rural areas, determined strategic models and foundations for increasing the level of its competitiveness and improving the quality of life of the rural population, worked out mechanisms of state support for the industry and analyzed the results of agrarian reforms. All this ensured the emergence of a significant number of scientific and applied developments, which are extremely useful for the theory and practice of increasing the effectiveness of development of the agricultural sector.

II. Methods

Current problems in the development of the agro-industrial complex and the use of resource-saving technologies and techniques are reflected in the scientific works of domestic and foreign scientists, in particular V.V. Aleksashina [1], P.V. Druzhinin [4], D.A. Zimin [4], Kh.Z. Mantaev [2], S.A. Nikolskaya [3], Z.P. Okazov [2], O.V. Potasheva [4], Z.V. Totikov [2], E.S. Tskhovrebov [7], G.T. Shkiperova [4] and others. However, most domestic agricultural enterprises have significant shortcomings that relate to the formation of an effective resource-saving management system in the context of the environmental component, which necessitates the need to find ways to improve their activities.

The purpose of the article is to study the theoretical and methodological foundations of the environmental component of resource conservation management of agro-industrial complex enterprises in the context of ensuring sustainable development, as well as to determine the impact of agro-industrial complex activities on the environment.

In the context of modern trends and changes in the management paradigm towards socially responsible business, financial, in particular, investment markets are quite sensitive to companies that carry out corporate governance on the principles of sustainable development. Experts have a clear consensus that social, environmental and economic behavior of businesses can significantly improve the financial performance and performance of companies. The implementation of sustainable development goals into the corporate strategy of companies helps to obtain long-term value for owners and investors, improve the corporate reputation of the company, and ensure an increase in financial performance indicators. Since the 90s of the last century, the economic literature has examined and confirmed the connection between socially responsible business behavior and its financial results. Today, the concept of social responsibility of business is expanding, complemented by the principles of strategic programs for sustainable economic development and approved at the level of government in individual countries and their associations. Recognizing business opportunities based on factors that take into account the preservation of the natural environment and the company's concern for social issues is now seen as a strategic factor in increasing business productivity and competitiveness. Business ideas that arise and are implemented on the basis of sustainable development form the potential for a company’s competitive advantages (new technologies, resources, products, markets), which increases the ability to generate profits and improve financial performance.

The main benefits from the implementation and implementation of sustainable development goals in the strategic management of companies can be identified as follows: 1) improvement of corporate image, which leads to improved financial performance; 2) increasing the level of investment attractiveness and expanding the financial and production potential of the company; 3) maximizing profits through better satisfaction of consumer needs and the formation of a reserve of competitiveness; 4) obtaining non-financial (social and environmental) benefits for a wide range of parties.

III. Results

Sustainable development of agriculture is part of the overall global concept of sustainable development until 2030, which was adopted in 2015. The universal principle of the concept of "sustainable development" is to meet the needs of the modern generation without risks and threats for future generations to provide for their own. The main emphasis of the concept of sustainable development of agriculture is a focus on meeting the needs of humanity (in terms of improving the quality of life of the population) in the conditions of preserving and restoring bio and ecosystems.

The introduction and implementation of the concept of sustainable development in the practice of domestic agribusiness should be accompanied by the delineation of clear positions, principles and elements that will form a unified architecture for sustainable development of agribusiness not only at the level of individual economic entities, but also at the level of agriculture, rural areas, the agro-industrial sector, as part of the national economy as a whole.

Agricultural production is a priority for the economy of any country and is important for the three main elements of sustainable development: ecology, economy and society. Solving the strategic problem of ensuring food security both at the national level and in the context of the global dimension in modern conditions is accompanied by significant environmental and socio-economic compromises. In particular, the need to increase food production volumes leads to the emergence of the problem of disappearance of biological diversity, the widespread use of GMOs, the loss of natural characteristics of biological resources, their modification, the acceleration of the main biological processes of transformation of biological assets based on an increase in the level of intensity of agricultural production (the use of chemicals, mineral fertilizers, drugs stimulating the growth and maturation phase of biological assets, etc.).

The range of environmental challenges and threats is complemented by socio-economic factors, among which the low level of income and quality of life of the population of rural areas, underdeveloped social infrastructure, a high degree of unemployment in rural areas and the intensification of migration processes are characteristic, which actually leads to the destruction of certain rural areas.

Despite the fact that in recent years the domestic agro-industrial complex has demonstrated stable economic growth, the problem of food supply for the country's population remains relevant both at the national and global levels.

Agriculture is a basic sector of the domestic economy, the level of development and efficiency of which today determine the strategic priorities of foreign economic trade, the possibility of forming the country's budget, ensuring food security and the raw material basis for the development of technologically related types of economic activity. The agro-industrial sector in the domestic economy represents the basis of economic development, forms the strategic prerequisites for attracting investments, strengthening the level of competitiveness of the national economy and improving the level of well-being of the country's population. Solving these problems is impossible without ensuring the effective development of agribusiness, solving problems of improving the quality of life of the rural population and food supply for current and future generations.

Crop and livestock production have a major impact on the environment. They are the main source of water pollution with nitrates, phosphates and pesticides. The agricultural sector is also the main anthropogenic source of greenhouse gases methane and nitrous oxide, and also contributes to other types of air and water pollution [6]. Agriculture also has negative impacts on the environment due to land degradation, salinity, over-extraction of water and reduction in genetic diversity of crops [3].

Most modern farms have abandoned skilled farming, which was once the leading principle of land cultivation. Today the emphasis is solely on productivity - it's a big expense for a high return.

Agricultural business owners do not take into account what happens to the land, crops and people consuming agricultural products [6].

More than two-thirds of water used by humans is for agriculture. Groundwater contamination from agricultural chemicals and wastes is a serious problem in almost all developed countries and, increasingly, in many developing countries. Water consumption, in turn, tends to increase.

Fertilizer contamination occurs when more fertilizer is applied than crops need, or when it is washed off or blown off the soil surface. Excess nitrogen and phosphate may leach into groundwater or flow into waterways. This nutrient overload causes eutrophication of lakes, reservoirs and ponds, leading to an increase in algae that overwhelms other aquatic plants and animals [1].

Domestic agricultural enterprises widely use insecticides, herbicides and fungicides in their activities, which leads to contamination of fresh water with carcinogens and other poisons that have a negative impact on the environment. Pesticides also reduce biodiversity by killing weeds and insects and, therefore, food species of birds and other animals [4]. The use of pesticides has increased significantly over the past few decades. In some regions, recent growth rates ranged from 4% to 5.4%.

Agriculture is also a source of air pollution. The dominant anthropogenic source of ammonia is livestock farming, which accounts for about 40% of global emissions, mineral fertilizers – 16%, and biomass burning and crop residues – about 18% [3].

The burning of plant biomass is another major source of air pollutants, including carbon dioxide, nitrous oxide and smoke particles. Projections show that by 2030, ammonia and methane emissions from the livestock sector in developing countries could be at least 60% higher than currently. Ammonia emissions from agriculture, according to forecasts by ecologists and economists, will continue to grow in both developed and developing countries [4].

Agriculture, forestry and fisheries negatively impact land and sea biodiversity. Species richness is closely related to wild habitat range. As the area decreases, so does the number of species. Deforestation, consolidation of fields with accompanying reduction of edges and hedgerows, and drainage of wetlands for agriculture are reducing the total area available to wildlife [2; 4]. Pesticides and herbicides kill many insects and plants, thereby reducing food supplies for some animals. Pressures on biodiversity over the next decades will result from contradictory trends. Extensive methods usually give way to intensification, which in turn may give way to organic agriculture [1].

The main directions of the negative impact of the activities of agricultural enterprises on the environment are: soil depletion and loss of soil fertility; soil erosion; nitrate runoff; soil compaction; loss of biodiversity; air emissions; groundwater pollution.

By using more sustainable production methods, the negative impact of agriculture on the environment can be reduced. Among the areas for reducing the negative impact on the environment from the activities of agricultural enterprises, the following can be highlighted: increasing the efficiency of fertilizer use; distribution of rice varieties that emit less methane; improving livestock waste management; restoration of degraded lands; improving crop residue management; expansion of agroforestry and reforestation; supporting the mobility of livestock in pasture areas prone to drought, etc. In particular, the use of agricultural waste will help increase the energy autonomy of agricultural producers.

IV. Discussion

At the same time, part of the produced energy can be sent for sale to third-party consumers, which will help reduce greenhouse gas emissions into the atmosphere and strengthen energy independence. However, the effective use of biofuel to obtain energy in agricultural production, and especially from agricultural waste, requires optimization of technical and technological processes for the production and use of biofuel and scientific technical justification of the rational parameters of machines and equipment used for the production of biofuel and the production of energy based on it.

The transition of the agricultural sector to a new level of development is possible only under the condition of a radical change in the nature of the development of productive forces, a rejection of the extensive type of economic growth, and a transition to intensive factors. To do this, it is necessary to solve the problems of rational, economical use of resources. Therefore, the state and the managers of agricultural enterprises are faced with the task of ensuring effective resource conservation [2; 4].

Resource conservation management of agricultural enterprises should be a comprehensive process associated not only with improving economic and social efficiency indicators, but also contain an environmental component [7]. The group of indicators characterizing the environmental efficiency of resource-saving management of an agro-industrial complex enterprise includes the following coefficients (Table 1).

Table 1. *Main indicators of environmental efficiency of an agricultural enterprise*

Indicators of efficiency of resource-saving development	Characteristic	Possible threshold value/normative value
Nature intensity coefficient	Ratio of costs of used natural resources to net income from sales	Decrease
Natural resource productivity coefficient	Ratio of net income from sales to expenses of used natural resources	Increase
Ecological intensity coefficient	Characterizes the level of harmful effects on the environment per unit of useful product	Decrease
Resource intensity ratio	Characterizes the costs of energy, water, land and other resources per unit of useful product	Decrease
Eco-Friendly Factor	Ratio of purely beneficial effect to spent natural resources	≥ 1
Waste capacity coefficient	The ratio of the mass of waste reduced to a single volume, taking into account differences in the degree of their harmfulness per unit of production	Decrease
Ecological production factor	The difference between the cost of raw materials taken from 1 and the cost of waste produced	→ 1

It is advisable to calculate the integral indicator of management of environmental efficiency and resource saving using the formula:

$$\text{К экол.эф.} = \sqrt[7]{К1 * К2 * К3 * К4 * К5 * К6 * К7}$$

where K1 is the environmental intensity coefficient; K2 – coefficient of natural resource productivity; K3 – environmental intensity coefficient; K4 – process resource intensity coefficient; K5 – coefficient of environmental friendliness of the object; K6 – waste capacity coefficient; K7 – coefficient of environmental friendliness of production.

In conditions of limited resources and increased competition, resource conservation ensures the sustainable development of agricultural enterprises, which leads to the need to resolve issues of organizational and personnel support for business entities [4]. The formation of an effective management system for resource conservation of agricultural enterprises should include a number of components (management system; organizational support; financing; motivational programs) included in the culture of resource conservation.

The culture of resource conservation should become an obligatory element of the general culture of personal behavior and the culture of professional activity of employees of agricultural enterprises. The formation of resource-saving behavior of personnel should become an element of the corporate culture of a business entity [4].

The main stages of forming and adjusting the organizational culture at an agro-industrial complex enterprise, which contains a resource-saving component, are the following:

Stage I: analysis of the state and prospects of organizational culture regarding the presence of a resource-saving component.

Stage II: development of a resource saving strategy (defining priorities, principles, norms, patterns of personnel behavior, etc.).

Stage III: planning activities aimed at mastering the norms and values of resource conservation.

Stage IV: influencing the organizational culture in order to minimize ineffective methods of using resources, developing positive traits that will contribute to resource conservation.

Stage V: assessing the effectiveness of the impact on organizational culture and adjusting the necessary actions.

Today, agricultural production is witnessing a decline in productivity due to degradation of natural resources, increased biotic and abiotic stresses, low seed replacement rate, damage to the natural ecosystem due to excessive and indiscriminate use of pesticides, changes in soil microbial dynamics, lack of quality plasma, etc.

According to the forecasts of ecologists and economists, it is expected that in the coming decades, climate change will not lead to a decrease in global food availability, but it may increase the state's dependence on food imports and weaken the level of food security.

The implementation of the concept of sustainable development in the practical activities of agricultural enterprises today creates real economic benefits for all participants in the process of public agricultural production and development of rural areas. The beneficiaries of the results of activities based on the principles of sustainable development are: 1) agricultural producers who can improve the quality and competitiveness of products, maximize revenue and profit from the sale of environmentally friendly products and expand the sales market, attract additional financial flows in the form of investments in environmental agricultural production; 2) employees who are participants in social and labor relations, guaranteeing staff high standards of quality of working life; 3) residents of rural areas who receive bonuses from ecological land use, environmental improvement, conservation of natural resources, investments in the development of infrastructure for the implementation of investment projects for sustainable development, including those of a social nature; 3) food consumers who will be able to consume high-quality, environmentally friendly and safe food products; 4) regions, the state and society as a whole due to economic growth in the agro-industrial sector, which today appears to be the basis for economic development, solving the problem of ensuring food security, improving the quality of life of the country’s population, taking into account the interests and needs of future generations.

The development of the domestic agro-industrial complex at the present stage is characterized by the presence of a significant number of acute problems, but at the same time, domestic agricultural business remains one of the most effective and profitable types of economic activity. Preserving and increasing the development potential of agribusiness and rural areas today cannot be ensured without strategic initiatives to implement the concept of sustainable development, the foundations of which are now quite clearly outlined in domestic science and practice. Strategic priorities in the context of the concept of sustainable development should become a guideline for the domestic agricultural sector, not only to increase the level of competitiveness of the national agro-industrial complex, the level of quality of residents of rural areas and solve the problem of ensuring food security, strengthening the domestic economy, meeting the needs of the country's population and its future generations. The key tools for achieving the goals of sustainable development of agriculture and rural areas should be science, innovation and modern digital technologies, and sufficient financial support for strategic and current development programs.

Current problems of environmental protection and conservation of natural resources in today's conditions are of great importance. More and more domestic agricultural enterprises are concerned not only about making a profit, but also about how to minimize the negative impact on the environment. One of the effective directions for the development of agricultural enterprises is to increase the efficiency of resource conservation management not only in the context of the economic component, but also the environmental one.

ismetahmadov@mail.ru

Abstract

Since the 18th century, as human activity intensified, climate changes on our planet became global. These changes create complications of different nature in different areas. There are three important categories of action for reducing the risk of global climate change: reducing emissions, adapting to climate impacts, and financing required adjustments. The plant world is the most important among the living systems affected by global climate changes. That is why adapting plants to these changes, in other words, increasing their durability, is one of the most important issues of modern horticulture. It has already been proven that nanotechnology plays an important role in increasing plants' resistance to environmental factors (temperature, salinity, drought, radiation, etc.). In the presented review article, the scientific articles of recent years have been analyzed and it has been shown that nanoparticles play an important role in plant development, productivity, important physiological and biochemical, molecular processes and resistance to stress factors. The number of studies and investigations dedicated to this field is observed with exponential growth. In the article, the research of recent years and the results obtained from our own experiences are highlighted. It has been shown that nanoparticles can produce both positive stimulatory and toxic effects in plants, depending on their type, physical and chemical properties, dose, exposure time and application methodology. It has been noted that nanoparticles play an important role in the mineral nutrition of plants, protection, and formation of effective responses to stress factors.

Keywords: nanotechnology, nanoparticles, plants, stress factors, drought, salinity.

I. Introduction

Since agriculture operates as an open system where energy and substances are freely exchanged, the production processes here are unique. The most affected by the consequences of global climate change is the agricultural industry. Therefore, concern about the potential effects of long-term climate change on agriculture has grown significantly in the past decade and has been the subject of many studies. These studies are mainly devoted to the elimination of possible physical effects associated with climate changes in crops and livestock. Although the methods and technologies used in agricultural production have an ancient history, each of them has always kept its relevance. Nanotechnology, determined to gain the status of technology of the 21st century, penetrates all areas of human activity in terms of its application. In recent years, the application of nanotechnology in agriculture has been noted as a major issue in the economic interests of all countries of the world from the point of view of investment. Research conducted by nanotechnology in the fields of plant physiology and biochemistry, agronomy, plant protection, productivity, product quality and packaging is giving positive results. To increase productivity in agriculture, nanotechnology offers new effective agrochemical agents, fertilizers, pesticides and herbicides, tolerance methods, smart packaging technologies.

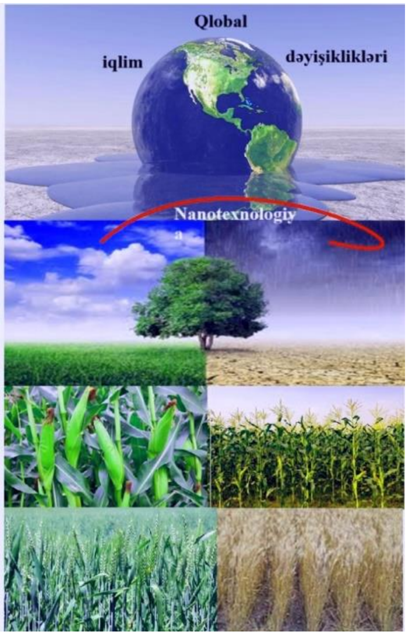

Figure 1: *Global climate change and nanotechnology*

The applications of nanotechnology in agriculture to increase productivity, improve production technologies, and modernize irrigation and agro technical methods include (1) the use of Nano forms of agrochemicals in the application of pesticides and fertilizers to improve and increase yields; (2) the application of Nano sensors in plant protection for identification of disease and chemical toxicant residues; (3) application of Nano devices for genetic engineering technology in plants; (4) application of Nano sensors in the diagnosis of plant diseases; (5) application of Nano technological methods in animal health, animal husbandry, poultry production; and (6) use of nanomaterials in post-harvest storage and packaging. What results of research conducted in the field of nanotechnology can be used in the application of intensive technologies in agricultural practice?

II. Interaction of nanoparticles with plants.

NPs can enter plants from air, soil, irrigation water, and seeds. NPs entering the organs and tissues and cells of plants cause many morphological and physiological changes depending on their characteristics. The effectiveness of NPs is determined by their chemical composition, size, surface coverage, reactivity and, most importantly, the effective dose. Studies have shown that NPs can have both positive and negative effects on plant growth and development, resistance to stress factors, and disease protection. In our experiments and the research of other scientists, it was determined that NPs can enter the seeds of plants, are absorbed from the endosperm layer of the embryo and migrate from the roots to the above-ground organs [1, 2].

From our experiments [2] and from the results of experiments by Lv. Christie and Zhang [3], it was clear that NPs penetrate the seeds and improve their water absorption, which leads to an increase in the intensity of seed germination. Nano hydrates can penetrate plant roots through osmotic pressure, capillary forces and pores (5-20 nm) in the cell wall [4]. The effects of some nanoparticles on plant development and important physiological processes are listed in Table 1.

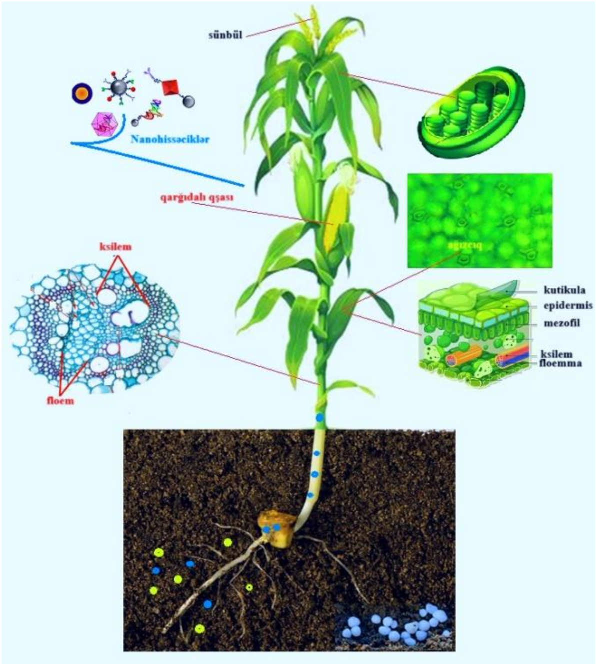

Figure 2: *The main areas of accumulation and action of nanoparticles in plants: root, seed, stem, leaf*

Table 1: *Effects of some nanoparticles on the plant developments and important physiological processes*

Nanoparticles	Plant variety	Possible effects and mechanism	References
Zn O	*Pennisetum americanum*	It increases the activity of certain enzymes	[5]
	Onion, Rice, Wheat	Disruption of cell metabolism, reduction of root length and reduction of plant biomass.	
Cu O	*Egeria densa*	Accelerates lipid oxidation, increases SOD and catalase activity	[6]
	Tomatoes, pigeon peas	It enhances root length, plant height, dry and fresh weight of seedlings, and intensity of photosynthesis	[7]
Ag	*Lactuca sativa*	It can accumulate in the leaves, it does not show any phytotoxic effect Accelerates the growth of sprouts Does not affect soil environment	[8]
	Phaseolus radiates *Sorghum bicolor* *Daucus carota L.*	Reduces germination rate, increases seed number, protein, chlorophyll content and H_2O_2 Strengthens root regeneration	
Au	*Xrizantema, gerbera & primrose*	Increases productivity, germination rate, growth and radical scavenging activity	[9]
	Arabidopsis thaliana	Increases germination, plant height, leaf length, diameter without showing toxicity at 5.4 ppm	
	Allium cepa L.	It increases the average length of roots, biomass, and reduces the number of leaves of seedlings	
Al_2O_3	*Nicotiana tabacum*	Reduces biomass but increases K+ uptake, increases macronutrient uptake	[10]

		in roots and leaves	
SiO_2	*Solanum lycopersicum* L.	It enhances the activity of a number of enzymes in the leaves and seeds, and also promotes the absorption of nitrate	[11]
TiO_2	Spinach	Increases Fe, P and K content in leaves, improves photosynthetic performance and Fe and P availability, accelerates plant growth	
Fe_3O_4	*Triticum aestivu*	Prolonging the exposure time accelerates plant growth, has a positive effect on VC content, and does not increase fruit weight.	[12]
γ-Fe2O3	*Cucumis melo*		

III. The role of nanoparticles in the resistance of plants to stress factors

The most serious problems caused by global climate changes in agriculture are related to drought and soil salinization. Both of these stress factors cause serious changes in plant organs, tissues, and important physiological processes (growth and development, photosynthesis, respiration, mineral nutrition, etc.) and ultimately stop the life activity of plants, reduce their productivity, and in most cases lead to their destruction. Experiments show that the application of nanoparticles in solving this problem can play an important role in plants' fight against stress factors. The results of experiments performed with the application of nanoparticles in recent years show that various metal-based nanoparticles, carbon nanotubes, and nitrogen oxide nanoparticles increase the resistance of plants to stress factors and are a promising field of research. In this type of experiment, it is possible to clarify the mechanism of the effect of nanoparticles on plants and the role of nanoparticles in the formation of responses to various stress factors. Plants develop early stress signalizing mechanisms to counter abiotic stressors and increase tolerance. When plant cells are stressed, they form and amplify secondary signals such as calcium, reactive oxygen species (ROS), phospholipids, and nitric oxide (NO), as well as various protein kinases. These signals include SnRk1 kinases that alter the expression of about 1000 stress-sensitive genes, ABA and ethylene plant hormones that act as key signals for stomatal closure and plant defense responses during drought stress [13]. These stress signals activate transcription factors, which further activate various stress-response genes to cope with the harsh effects of abiotic stress.

Salinity stress and nanoparticles. 20% of cultivated lands worldwide (35% in Azerbaijan) face salinity stress, which is the main type of abiotic stress factor, and this amount is increasing day by day due to global climate changes. Salinity is mainly caused by an excess of sodium chloride (Na Cl). High levels of Na Cl cause at least three types of problems for higher plants: 1) a higher osmotic pressure in the external environment (in solution), compared to the intracellular osmotic pressure, 2) high concentrations make it difficult to absorb and transport nutrient ions such as Na, K, and Ca, 3) Both Na and Cl ions can have direct toxic effects on membranes and enzyme systems. To combat salt stress, plants are well equipped with a defense system of various antioxidant enzymes including superoxide dismutase (SOD) and peroxidase (POD). Using the achievements of nanotechnology to reduce the negative effect of salt stress is one of the urgent issues of the day. The contribution of nanoparticles to the solution of this problem in the research of scientists is promising. From the results of our experiments with cotton plants, it is clear that when cotton seeds are treated (coated) with Al nanoparticles, they grow well in saline soils. In the initial stages of plant development, the amount of chlorophyll a and b pigments in the leaves increases, Al nanoparticles reduce the increased activity of key enzymes such as ascorbic peroxidase during salt stress. This decrease is slight in polyphenol oxidase but appreciable in guaiacol peroxidase enzyme. Hussain and Abu-Baker [14] sprayed a solution of Zn O nanoparticles on the leaves of a cotton plant irrigated with seawater to reduce the negative effect of salinity. It was clear from their experiments that application of Nano-Zn O reduced phosphorus (P) uptake and translocation to leaves, resulting in lower P/Zn ratio. They suggested that extra dose of P-fertilizer with Nano-Zn should be used to overcome P/Zn imbalance.

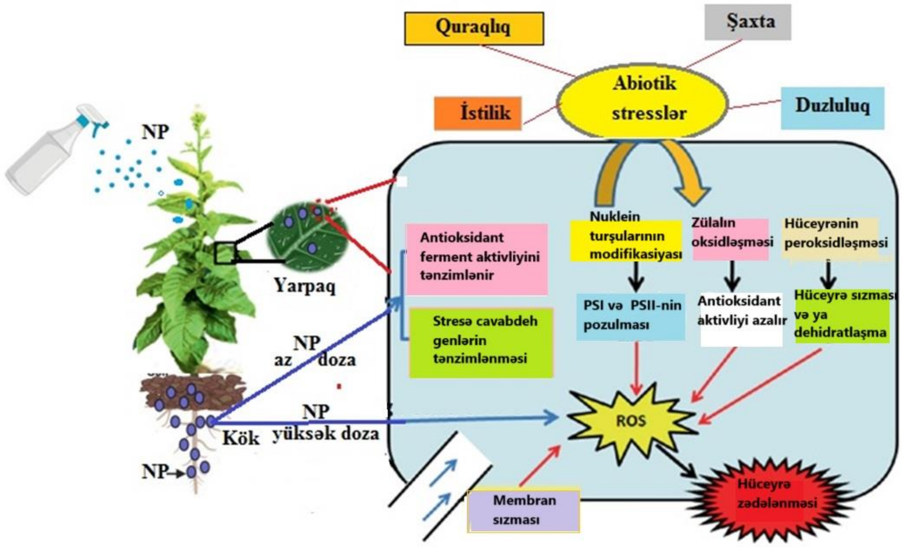

Figure 3: *Effects of nanoparticles on plants under stress conditions*

Avestan et al., [15] used SiO_2 nanoparticles to overcome the effect of salinity stress in their experiment. They managed to improve the morphological and physiological changes in strawberry plants during salt stress using SiO_2 nanoparticles. They found that nanoSiO_2 increased chlorophyll content in salt-stressed plants and maintained better leaf relative water content (RWC) and relative water conservation (RWP) compared to control.

Drought stress and nanoparticles. Plants on our planet have been constantly fighting water stress for millions of years, from the moment they emerged from water to land. As drought occurs, most higher plants are forced to adjust their life cycles to tolerate or avoid this stress. Therefore, drought has been the main driving factor for the evolution and diversification of arid plants. This important environmental factor always remains the main obstacle to agricultural production. For plant physiologists, the concept of "drought" does not simply mean lack of water, it means (1) low soil moisture; It means (2) high evaporation potential, (3) high-temperature conditions, (4) high solar radiation, (5) increased soil hardness, (6) lack of mineral elements, and (7) accumulation of salts in the topsoil.

Experiments show that as a result of the application of nanoparticles to plants in drought conditions, antioxidant enzyme activity increases, phyto hormone levels improve, and important changes in physiological properties occur, and as a result, the effect of drought on plants is reduced. The effects of Fe_2O_3, Zn O and TiO_2 nanoparticles on the development, productivity, biochemical and morpho-physiological parameters of plants under drought conditions were investigated in our experiments with corn plants grown in field conditions. It was determined that nanoparticles have a stimulating effect on plants grown in drought conditions. Plants whose seeds were treated with TiO_2 nanoparticles grew more intensively regardless of drought stress and plant height increased by 1.5 times compared to the control. The height increase was 1.6 times greater than the effect of Zn O nanoparticles, and 1.17 times greater than the effect of Fe_2O_3 nanoparticles. GPX activity significantly increased in the drought variant. This was 20-25 per cent higher than the activity under irrigated conditions. Nanoparticles also reduced GPX activity in the drought variant. At this time, the effect of Zn O nanoparticles was greater. Application of Zn O nanoparticles to soybean plants under drought conditions increases seed germination percentage, application of Cu and Zn nanoparticles to wheat plants increases relative humidity and antioxidant enzyme activity, stabilizes photosynthetic pigment content in leaves, reduces accumulation of thiobarbituric acid, reagents, and consequently reduces stress effects. Application of SiO_2 nanoparticles under drought stress reduces superoxide radical generation and membrane damage but increases shoot length and relative water content in barley. Application of Cu O nanoparticles to maize under drought conditions increases leaf water content, plant biomass, anthocyanin, chlorophyll and carotenoid content. Drought stress increases the negative effect of Cd element in wheat plant, but as a result of application of Zn O nanoparticles, the effect of both Cd and drought stress is weakened. The results of the experiments showed that the use of silver nanoparticles increases the germination percentage of lentil seeds and the growth rate of seedlings under drought conditions [16].

IV. Conclusion

A review of the scientific literature shows that nanotechnology, which has found many different fields of application in the last few decades, has begun to form a powerful scientific field. Nanotechnology is used in medicine, agriculture, industry, environment, engineering, and electronics, and is revolutionizing various fields. Nanotechnology is emerging as an important technology to strengthen and modernize agriculture in particular, which is an important tool to overcome food poverty and malnutrition, and the consequences of global climate change. A large number of extensive studies have determined that nanoparticles can provide beneficial effects on the development and growth of plants, increase productivity, and help eliminate biotic and abiotic stress factors. In perspective, the use of nanotechnology will create a powerful platform and enable a safe and stable future in sustainability, productivity, quality, diagnostics and smart packaging. It will be able to minimize product losses. The most effective way to understand the nature of the mechanisms of application of nanomaterials is to cooperate with such fields of science as molecular biology, plant physiology, plant biotechnology, cytology, soil physics along nanotechnology. Such collaborations can be useful for promoting multidisciplinary projects that can be implemented worldwide. In order to deepen the physiological research on nanotechnology, new ideas about the mechanism of tolerance to various abiotic stresses in plants are formed. The application of nanotechnology should be commercialized from the laboratory to the agricultural fields.

Abstract

The historical method, abstract and logical methods, comparative and statistical methods were applied within the research. The characteristic of digital currencies of Central Banks, their differences from cryptocurrencies is presented, possible models of their functioning are considered in the article. Some regularities between the needs of consumers for which the digital currency is issued, and the features of its design are offered. The international experience of digital money introduction is analyzed and some conclusions are drawn on the advantages and prospects of this tool. The authors conclude that the transition to digital currencies will lead to faster innovative development of the bank and monetary-and-credit systems and the payment market as well. The conclusions and recommendations, drawn in the article, can be useful for the specialists occupied with the development of approaches to realization of digital national currencies, development of their design. The authors of the article consider an innovative form of money, digital monetary unit or digital currency.
The authors conclude that the transition to digital currencies will lead to faster innovative development of the bank and monetary-and-credit systems and the payment market as well. The conclusions and recommendations, drawn in the article, can be useful for the specialists occupied with the development of approaches to realization of digital national currencies, development of their design. The authors of the article consider an innovative form of money, digital monetary unit or digital currency.

Keywords: digital economy, innovation, payment market, digital currency, banking instruments

I. Introduction

In Russia the Central Bank of the Russian Federation started the development of the concept of digital rouble in 2020. In October, 2020 it published the special report for public consultations, in which the advantages of digital currency were described. In the conditions of the innovation economy new requirements to the communications, computing power, information systems and services appear. The innovation technologies development caused the emergence of a new form of money existence – digital currency (Plehova et al. 2020), (Bank for International Settlements, 2022; (Yakunina, 2022), (Imangozhina et al,2019), (Ivanova O. 2020), (Tutova V.A., 2024), (Yarovenko, 2021), (Khalilova, et al. 2022), (Kodasheva, G. et al, 2022), (Burkaltseva et al. 2022), (Rudyk et al,2022), (Petrova et al.,2022), (Niyazbekova &,Troyanskaya et al, 2021), (Patashkova, Y. et al.,2021), (Evmenchik, 2021), (Jazykbayeva, 2021), Niyazbekova, 2021), (Abramova et al.,2023), (Grekov, et al., 2016), (Niyazbekova et al., 2021;2023), Yakunina et al (2022), Mikhaylishin (2021) Kucherov I.I. (2018) Eskindarov M.A. et al. (2019) Andryushin S.A. (2019).

In April, 2021 the expert discussions took place in Russia; the discussion came to the end with the publication of the concept of digital rouble, which described the role, possibilities of application as well as the models and mechanisms of the use of digital currency (Bank of Russia, 2020; 2021; 2022)[1]. Converting of cash or non-cash rouble into digital rouble will be performed as 1:1. Client will be able to save his or her funds in case of bankruptcy of the financial institution working with digital currency. Funds will be available through other financial institution as the actually monetary unit belongs to the Central Bank of the Russian Federation.

Moreover, according to the glossary of Committee on payments and market infrastructure of Bank for International Settlements, electronic money is defined as "the cost stored in an electronic form on the device like the smart card or the hard drive of the personal computer" (Bank for International Settlements, 2020[2]).

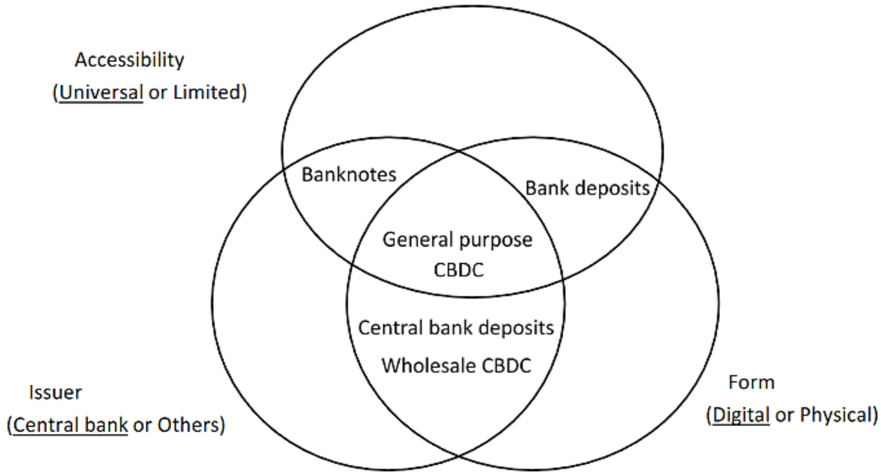

Figure 1: *Classification of Currency (according to Bank of Japan, 2020)*

Most representatives of Central Banks considered digital currencies of Central Banks (especially retail CBDC) negatively or scornfully up to 2019.

Many scientific works, devoted to digitalization of economy in general and the payment market in particular, were written from the moment of the beginning of work on the creation of digital rouble. The authors consider such Russian authors as Eskindarov M.A. (2019), Andryushin S.A.(2019), Serebrennikova et al. (2021), Mikhaylishin A.Yu. (2021), Kucherov et al. (2018), Tobin J. (1987) et al. to deserve attention. However, not all the matters have been taken rather up. For example, it is required to develop some recommendations on the choice of option of digital currency design, depending on the needs of their potential consumers.

II. Methods

Official data of Central Bank of the Russian Federation (Bank of Russia, 2020; Bank of Russia, 2021), Sveriges Riksbank (2022), Deutsche Bank (2022), People's Bank of China (2017)[3], Bank of Japan (2020)[4], etc. as well as the reports of analytical agencies served as epy materials for this research.

Historical method, abstract and logical methods, comparative and statistical methods were

applied within the research.

Official data of Central Bank of the Russian Federation (Bank of Russia[5], 2020; Bank of Russia, 2021[6]), Sveriges Riksbank (2022), Deutsche Bank (2022), People's Bank of China (2017), Bank of Japan (2020), etc. as well as the reports of analytical agencies served as epy materials for this research.

Historical method, abstract and logical methods, comparative and statistical methods were applied within the research.

Official data of Central Bank of the Russian Federation (Bank of Russia, 2020; Bank of Russia, 2021), Sveriges Riksbank (2022), Deutsche Bank (2022), People's Bank of China (2017), Bank of Japan (2020), etc. as well as the reports of analytical agencies served as epy materials for this research.

Historical method, abstract and logical methods, comparative and statistical methods were applied within the research.

III. Results

In Russia the Central Bank created the prototype of the platform of digital rouble by the end of 2021. 2022 The first pilot group consisting of 12 banks which assets are 70.4% of the total assets of 328 credit institutions for the end of 2021 was created for its testing in January (Table 1).

Table 1: *Structure of pilot group on digital rouble testing (Bank of Russia, 2022)*

Bank	Position in the rating according to the volume of assets	Volume of assets in the end of 2021, trillion roubles	Western sanctions against the bank after 24.02.2022
Sberbank	1	38.284	Blocking
VTB	2	19.361	Blocking
Gazprombank	3	8.707	Absent
Alfa-Bank	4	5.612	Blocking
Promsvyazbank	6	4.045	Blocking
Rosbank	11	1.579	Absent
Tinkoff Bank	13	1.278	Absent
DOM bank.RF	16	0.913	Absent
Ak Bars Bank	20	0.66	Absent
TKB bank	37	0.208	Absent
Sinara bank	57	0.116	Absent

The analysis of the world practice showed that though many countries go to creation of the digital currencies in a similar way, they can choose different models for their realization.

Types of architectures of retail CBDCs (Fig.2).

[5] Bank of Russia (2021) Concept of digital rouble. Moscow. 31 p. URL: http://www.cbr.ru/Content/Document/File/120075/concept_08042021.pdf (date of the address: 12.08.2024)
[6] Bank of Russia (2021) Concept of digital rouble. Moscow. 31 p. URL: http://www.cbr.ru/Content/Document/File/120075/concept_08042021.pdf (date of the address: 12.08.2024)

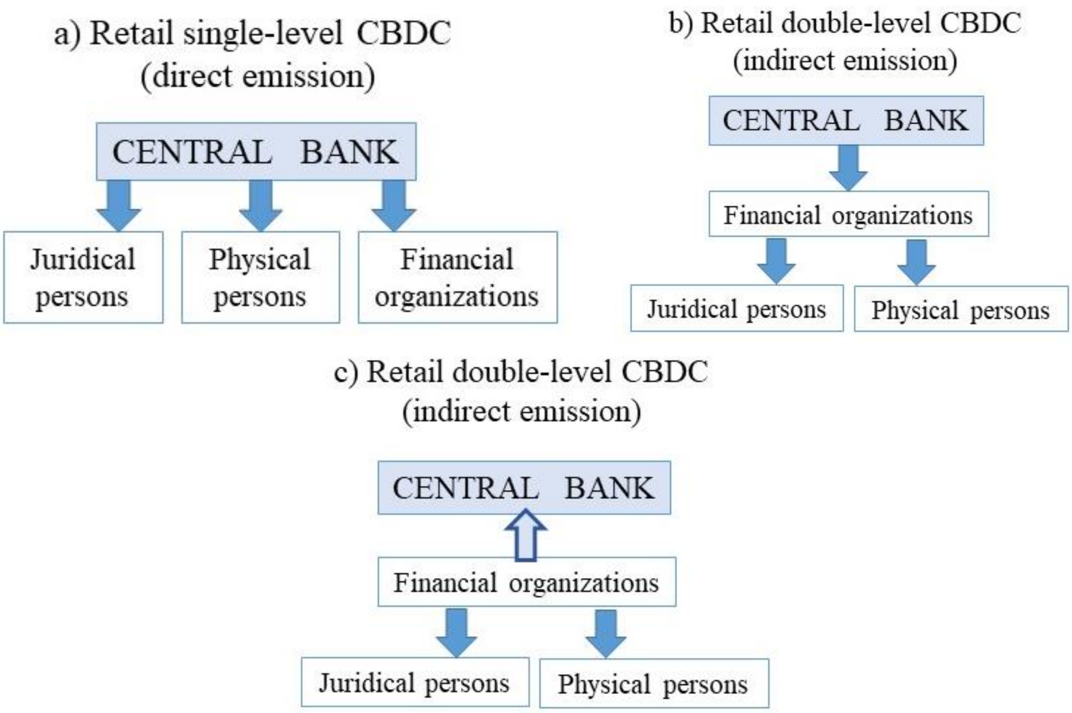

Figure 2: *Types of architectures of retail CBDCs (created by the authors)*

E-CNY has two-level structure, according to PBOC. But from the users' point of view, the model has more than the levels (Figure 3).

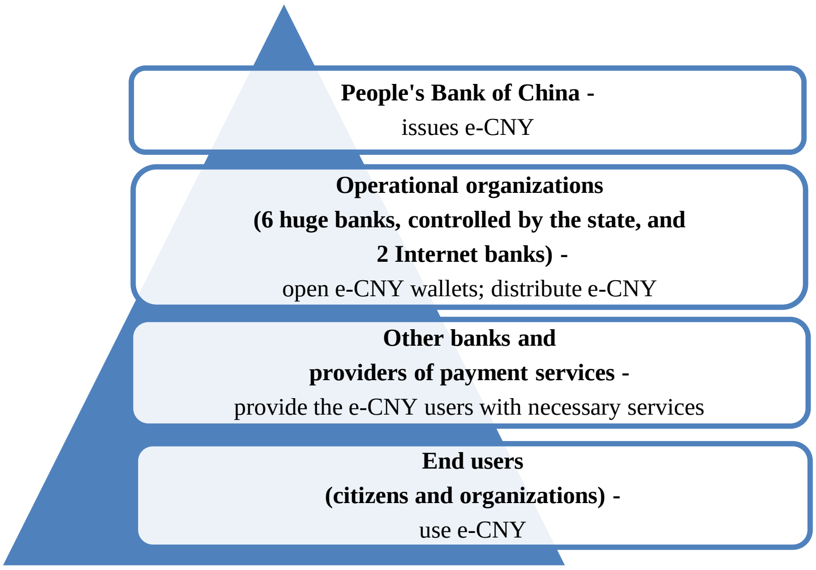

Figure 3: *Structure of the e-CNY model*

Source: created by the authors according to (Deutsche Bank, 2021)

The regulator of China considered the possible negative effect for "usual" national currency

The analysis of the world practice showed that though many countries go to creation of the digital currencies in a similar way, they can choose different models for their realization.

As for Russia, the two-level model, in which there are elements of the centralized system and the decentralized registers on the basis of blockchain technology was accepted. The first one provide large-scale data handling, and the second one allow to increase the efficiency, reliability and speed of transactions. The system of tracking and calculations among the participants (clearing) which maintains the register of the stream of means and their ownership is an important part of all process (Yakunina et al., 2022). Such model is most available to citizens and organizations and can be integrated into the bank infrastructure for customer service. The Central Bank allows to open virtual wallets for the users and allows financial institutions, Federal Treasury and other authoritiesto perform operations.

There is no universal option of the digital currency design. According to the authors of the article, the features of the digital currency design are determined by the consumers' needs. The authors' recommendations on the matter are provided in Figure 4.

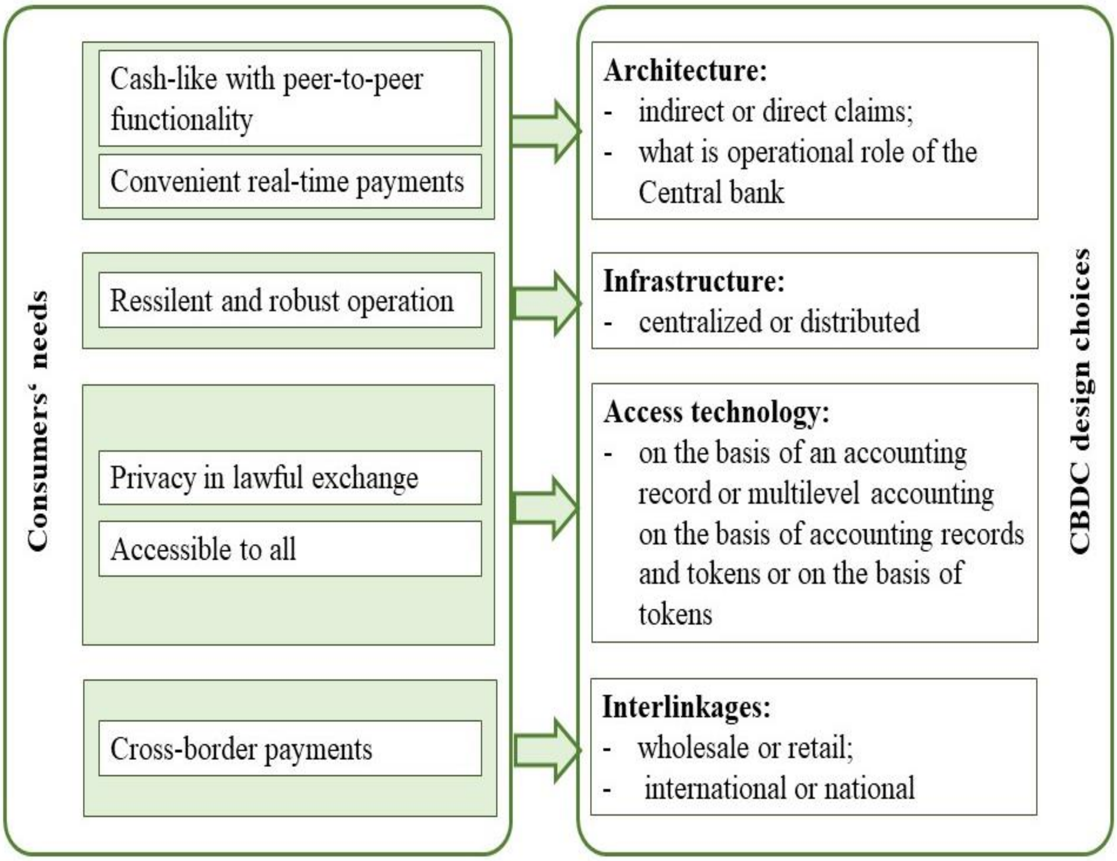

Figure 4: *Choice of Central bank digital currency according to the consumers' needs (drawn by the authors according to BIS Working Papers, 2020 and Kumhof & Noone, 2018)*

IV. Discussion

The accelerated digitalization was also strongly influenced by the coronavirus pandemic, which stimulated people to choose contactless and cashless payment.

Nevertheless, there is no consensus about the matter, how digital currencies are capable to perform the main and commonly accepted functions of money, among scientists and practicians.

Respectively, all three forms of Russian rouble will be absolutely equivalent (Bank of Russia, 2020). But this statement is debatable. According to other economists, digital money cannot be the store of value or to perform functions of means of accounting and payment (these two functions continue to be performed by official money) (Bouveret, Haksar, 2018).

However, digital currencies have to overcome some obstacles: their cost has to be stabler; they have to become convenient both to sellers, and consumers; their transition to the legitimate legal framework, legal regulation improvement are required; integration of digital currencies by leading companies in the field of payments (mobile applications, providers of bank cards) as well as large retail sellers.

At the same time payment and investment services are the kind of financial services. With respect thereto digital currencies can be considered not as money, but as a special financial instrument. According to other economists, digital money cannot be the store of value (Banque de France, 2018) or to perform functions of means of accounting and payment (these two functions continue to be performed by official money)

Studying of analytical reports and scientific works on CBDC proves that nobody among accounting or practicians knows definitely, what such innovation will lead to.

At the same time, reduction of dependence of users on certain providers will increase stability of a financial system of the country (Bank of Russia, 2020).

According to other economists, digital money cannot be the store of value (Banque de France, 2018) or to perform functions of means of accounting and payment (these two functions continue to be performed by official money).

Thus, this innovation is very perspective and capable to bring great benefit to modern economy. Soon we can expect transition from cash and traditional forms of non-cash payments to completely digital forms of money which will significantly change the payment market, bank and monetary-and-credit systems.

Besides, external restrictions and "freezing" of assets are not dangerous for such a form of calculation as digital currency. That is one of the reasons, why the sanctions of 2022 will even accelerate the introduction of digital rouble for the calculations in the Russian economy. There are all the reasons to expect, that digital currencies have great prospects.

Abstract

This article examines the problems of development of agricultural production in Russia. The author notes that the market processes of the last century in the Russian economy especially negatively affected those employed in the agricultural sector. There was a significant decline in the country's production of agricultural products, less sown areas, harvested grain, livestock, which were both the causes and consequences of the decline in the agricultural sector of labor remuneration and employment. The author found that the growth of employment in private subsidiary farming was a forced measure in the conditions of low wages of workers in the agricultural sector. The paper explores the possibility of developing many areas of agrarian production in the Chechen Republic, where there are not only natural and climatic conditions for this, but also a sufficient number of labor force. According to the author, the development of agricultural production in the region will provide jobs for a significant part of the local population. The necessity of material support from the state, the formation of appropriate legislative and tax systems in solving this problem is conditioned.

Keywords: agricultural production, employment, wages, Chechen Republic, rural areas, rural industrial enterprises

I. Introduction

Revival of the agrarian sector in the socio-economic development of the Russian state is considered among the main tasks of strategic nature. Agriculture as the basis of the agro-industrial complex in the country's economy plays a great role, since the food security of the state and the standard of living of rural residents depend on it. It is worth noting that Russian rural areas are home to up to 30% of its total population of more than 140 million people [1, c. 79]

Agricultural production, based on its ability to meet the needs of the country, is considered as an advanced sector of the Russian economy, which can meet domestic demand up to 90% for all major products. In the structure of Russian exports, agricultural products also account for a fairly significant share. Thus, in terms of wheat exports - 25 million tons, the country became the first in the world back in 2016, taking this place from the United States [2, c. 157]

II. Methods

Evstigneeva L. and Evstigneev R., note that one of the most important tasks facing Russia is the complication of its socio-economic structure as a prerequisite for the creation of a modern market economy. Such an economy is based on the tandem of large financial capital, which closely interacts with the state and regional markets. The more certain Russia's self-identity becomes in this respect, the more likely it will be a center of attraction for other CIS countries.

According to D. Samygin and A. Kudryavtsev, regions with favorable conditions for agricultural activity have a significant reserve for improving the efficiency of subsidies, which should be taken into account in the future when allocating state support funds.

According to Belousov R., the Russian economy was facing a challenge that had a “multidimensional” character: the growth potential was sharply decreasing due to external factors of development - high oil prices and increasing raw material exports; conditions for the development of non-resource sectors of the economy were deteriorating due to the expected opening of domestic markets; there was an urgent need for large-scale investments in the development of social and industrial infrastructure.

The work of Glazyev S.Y. and others is devoted to the study of the processes of market reforms development in Russia and their results. As the data analysis shows, by some indicators the country's economy was thrown back to the pre-revolutionary level, and even the war did not lead to such a long and deep decline in national production.

A. Emelyanov in his work analyzes the socio-economic structure of the Russian agrarian sector, developed in the course of its reform in the 1990s, determines the factors of improving the use of the potential of various forms of management, aimed at ensuring food independence of the country and the revival of the Russian village.

As Kashepov A. notes, institutions in the economy represent social norms, habits and behavior of subjects and at the same time large public, including state structures.

Basalaeva E. in her work focuses on such important problems of the agrarian sector as low incomes of the population employed in it, price disparity in industry and agriculture, reduction of the share of domestic food in the domestic market. The author pays much attention to the application of the most effective forms of distribution of funds allocated to the industry.

Uzun V. analyzes the processes of development of large and small businesses in Russian agriculture, determines the impact on their activities from natural, economic, ethnographic factors, as well as agrarian policy. The paper also presents the results of a comparative analysis of the efficiency of land and labor use by corporate, farm and private subsidiary farms.

Bogdanovsky V., studying the problem of employment in Russian agriculture in the years of market transformation, noted that there was a largely forced, large-scale transfer of labor from corporate farms to individual farms, as well as a significant decrease in labor profitability, actively developing underemployment, falling quality of human capital. Under such conditions, measures aimed at overcoming the industry's lag in labor profitability and developing alternative forms of employment for rural residents were important.

The work of Korotcheny V.M. notes the low efficiency of domestic agriculture compared to CIS countries and a relatively large technological gap with developed countries with a tendency to reduce. The author's calculations confirm the growth of efficiency of the Russian agricultural sector in the CIS beyond the time limit of the main study.

Buzdalov I., conducting socio-economic analysis of the nature and consequences of agrarian transformations in China and Russia, points to the presence of signs of a deep systemic crisis in the agrarian sphere of Russia in contrast to China. The author considers it important to use Chinese and foreign experience to achieve the priority of rural development in the country.

Bayrakov A.I. et al. study the natural landscapes of the Chechen Republic and their transformation under the influence of natural and anthropogenic factors as a prerequisite for a science-based approach to solving regional geo-ecological problems. The urgency of solving the existing problem is determined by ensuring environmental security and sustainable development of the region, which has long experienced anthropogenic impact, including military.

Abdulgalimov A.N. and Kurnosova T.I. consider very significant the problem of small innovative business development in the country, the solution of which depends on the possibility of transferring the economy to innovation rails.

Reshiev S.S., considering the nature and level of development of agriculture in the Chechen Republic, concludes that this production sector of the republic's economy still needs serious transformations and modernization, using the experience of successful analogues from the world and domestic practice.

Svetlov M.N. and others, analyzing the impact of state support of agricultural organizations on the revenue from the sale of agricultural products on the example of 14 Russian regions with significant differences in natural, institutional and technological conditions of agricultural production, emphasize the heterogeneity of state support effects for these territories.

Malyuk L.I. and others, studying the potential of non-agricultural employment, presented as a necessary form of employment of rural residents, believe that its development will largely solve the problem of unemployment in rural areas and increase the income of the rural population of the country.

When conducting this scientific research, such scientific methods as the method of comparative analysis, statistical analysis, comparative analysis, functional analysis, positive and normative analysis were applied. The scientific research was conducted in accordance with the problem-chronological principle, the principles of systematicity and scientific objectivity.

III. Results

The market transformation that took place in the Russian economy in the 1990s had a particularly negative impact on the situation of those employed in agricultural production. Thus, if in the agricultural sector of the country in 1990 there were about 8.3 million people, then in 1995 their number decreased to 6.7 million, in 2000 - to the mark of 4.7 million, and by the beginning of 2006 workers became 3 times less, i.e. 2.5 million. [3, p. 10] The number of cattle from 1990 to 1999 decreased by about 62% (from 45.3 million to 17.3 million); pigs - by 65% (from 27.1 million to 9.5 million); grain production decreased by 58%, i.e. 47 million tons instead of 113.5 million tons. 47 million tons instead of 113.5 million tons; the reduction in milk production reached 62% (from 41.4 million tons to 15.8 million tons); the area of agricultural land decreased by about 26% (from 202.4 million hectares to 152.7 million hectares), and of them the area under crops - by 35% (from 112.1 million hectares to 73.0 million hectares). [4, p. 56] If we consider the period 1990-2005, the plowed areas became less than 2 times less - only 51.4 million hectares instead of 112.1 million hectares; the number of cattle decreased more than 4 times, amounting to 10.9 million heads instead of 45.3 million [3, c. 10]

Employees of the agricultural sector in 1990 had an average labor remuneration reaching 95% of the average level in the economy as a whole, and compared to the same indicator in industry - up to 93%, but already in 2003 this indicator was only about 40% and 30%, respectively. [5, p. 125] Wages, as well as employment in the agrarian sector in the years under consideration decreased with a significant decline in agricultural production, reduction of livestock and cultivated areas, which can be considered both as a cause and as a consequence of these negative processes. The beginning of the 2000s was marked by the growth of wages in the agricultural sector, which increased by 46.6% in 2000-2001 and by 35.4% in 2002 relative to 2001. [6, p. 145] In 2004, of all those employed in the economy of the country, the workers of agricultural production accounted for 10.3% [7, p. 65], paid on average at the level of 43% of the similar indicator of urban residents. [8, c. 47]

During the period of market transformation of the 1990s and early 2000s, many people employed in the agricultural sector were forced to move to private subsidiary farms due to a significant drop in labor remuneration, which is not very high today. Thus, in 2002, the number of persons employed in their own farms of commodity orientation reached 3 million people, which could be compared with the number of employees of agricultural companies of large and medium-sized businesses, but still the vast majority of those working in private farms was noted in non-commodity production [9, p. 112]. Low incomes of agricultural workers could not but have negative consequences on the professional composition of the employed. Thus, at the beginning of 2003 only 16.9 thousand out of 86 thousand people who graduated in 2002 from agricultural universities, technical schools and colleges on a full-time basis, expressed a desire to work in the agricultural sector, i.e. every fifth person, only 18% were employed in their specialty, and this is with 30 thousand vacancies [10, p. 76]. This situation regarding employment in agricultural production and unemployment among rural residents is higher than in the city, required the state to develop certain measures for rural development, the purpose of which would be to increase the wages of agricultural workers, the growth of their professional level, increasing employment opportunities in rural areas, including through non-agricultural activities.

It is worth noting that only when agrarian policy is based on the special regularities of the development of agrarian relations and provides those employed in this production with the necessary socio-economic conditions, stimulates their labor productivity, it can be considered scientifically justified. Such a policy not only leads to the growth of food security of the country, but also makes it possible to have the status of a food power in the world. Here it is important to point out that neither crisis nor stagnation has practically no special influence on agrarian production.

IV. Discussion

How effective the country's agriculture should be determined based on comparative analysis with other countries on the basis of such, for example, non-parametric and parametric methods that establish the boundaries of production possibilities [11, p. 144]. Thus, for the development of social and engineering infrastructure in rural areas, the Chinese government implemented a protectionist "pro-peasant" agrarian policy, which attached importance to agro-industrial cooperation and integration. There were more and more national enterprises, which operated through "contract-orders" with family households, thus providing the opportunity to link together not only the processes of production, processing and marketing of the product, but also the supply of the necessary tools for this purpose. The structures that produce machinery and other equipment for the agricultural sector accounted for more than 130 million workers, producing products worth more than $500 billion [12, p. 138]. The implementation of these measures for rural development, in the implementation of which the state investment increased 30 times, provided China with a radical change in the socio-economic situation and to a greater extent in the agricultural sector, while before these reforms the country ranked only 125-130th in the world in terms of GDP per capita [12, c. 140].

To date, the following types of organizational and economic patterns can be distinguished in Russian agriculture:

- agricultural organizations hiring workers under contract;
- peasant (farmer) farms, where a contract may be drawn up when hiring workers or self-employment may be present;
- personal subsidiary farms that work on the basis of self-employment.

It should be noted that for the Chechen Republic the agricultural sector is one of the most important components of the regional economy, which can provide a significant part of its population with employment opportunities, thus reducing the number of unemployed, since the region has a fairly high proportion of rural residents - 62% as of January 1, 2021. [13] In agricultural production the decisive role is given to natural and climatic conditions, on which depends not only specialization, but also the very possibility for this activity. Accordingly, the location of various branches of this production in a certain territory requires taking into account the peculiarities of its soil and climatic zones. Although the Chechen Republic is small in terms of territory, it has a variety of climatic conditions for the development of many areas of agriculture. Thus, the region has nine soil-climatic zones with semi-deserts and sandy soils, steppes with chernozems, forests and mountain meadows. The soils are mostly chestnut, chernozem and meadow soils of good fertility; there are hot summers and short, rather mild winters against a background of different temperature conditions. Precipitation is uneven throughout the year, with more precipitation in June, while the least precipitation occurs between January and March. The region's river network is also uneven in distribution, with a densely branched river network in the mountainous part of the region and the adjacent Chechen plain, and almost none in the Tersko-Sunzhenskaya Upland and north of the Terek River [14].

In general, the natural and climatic conditions of the Republic allow to effectively develop not only the livestock industry, but also crop production, because with insufficient precipitation in most parts of the region, the presence of a developed network of rivers makes it possible to produce crops under artificial irrigation. For example, winter wheat yields well in mild winters, especially in the steppe and forest-steppe parts; the presence of plenty of heat ensures the production of grapes with a high sugar content, and the Naursky, Nadterechny and Shelkovsky districts are particularly suitable for this crop. Planting vineyards on the Zaterechnye stormy sands allows to use not only empty lands, but also to avoid many diseases of this crop. As experts note, in Soviet times in the republic collected up to 100 centners of grapes from one hectare, then sent it to different cities of the country by the day [15]. Also on the territory of the republic sunflower, gourds, especially in the farms of the Zaterezhnaya zone, have shown themselves to be highly profitable crops; good prospects for rice, the production of which requires the implementation of appropriate reclamation works. The high efficiency of production of cucumbers, tomatoes and herbs in greenhouses is confirmed by the example of "TC YugAroholding" LLC activity in the region, which gives an opportunity to both local residents and those from other regions to eat these vegetables of high quality in the winter season. Here it is important to note that among the main criteria of the efficiency of production activities of economic entities are the quality and quantity of products produced by them [16, c. 7].

It should be noted that there are geothermal sources in the republic, mostly in the foothills, the use of which in the production of greenhouse crops due to their cheap energy can be very profitable. Thus, in conditions of cheap energy, production of persimmons, pomegranates, oranges and other subtropical crops can be very profitable, but the problem is to solve the issue of purification of thermal water from the presence of highly corrosive substances. Natural and climatic features of terraces and sloping lands of mountainous areas are more suitable for mass production of various fruits and berries. Also alpine meadows of mountainous areas give all conditions for the development of meat cattle breeding, good conditions for honey production. In the stormy lands of the Shelkovsky and Nadterechny districts, fine-fleece sheep breeding gives good results. It is more desirable to use steppe and forest-steppe territories of the republic for dairy cattle breeding and poultry farming if there is a fodder base.

The development of agrarian production within the framework of the regional state program developed for this purpose provides for the creation of conditions necessary for the growth of living standards and employment of rural residents of the republic. The volume of agrarian production from all forms of agricultural producers - agricultural organizations, peasant (farmer) farms and households, calculated in current prices, in January-October 2023 in the republic, according to preliminary estimates, reached 39562.9 million rubles, exceeding by 14.8% the corresponding figure of the previous year [17]. Among the most priority areas of production within the framework of this program are considered vegetable growing, fruit growing, viticulture, which determine the overall sustainability of the entire agro-industrial complex and, to a large extent, the regional economy and import substitution; as a backbone sub-branch is presented cattle breeding, which provides for the production of milk, meat and uses significant areas of agricultural land [17].

The republic has been experiencing positive dynamics in the development of the livestock industry for a number of years. Thus, according to the results of calculations, the number of cattle for January-October 2023, attributable to the farms of all agricultural producers, amounted to 259.5 thousand heads, which was 0.8% higher than the same indicator of the previous year, of which the number of cows - 129.1 thousand heads, i.e. 1.7% more, and sheep and goats accounted for 299.3 thousand heads, indicating an increase of 1.7% compared to the corresponding values of the previous year [17].

It should be noted that for the growth of livestock productivity the most important is its pedigree composition. In the livestock industry of Russia, pedigree livestock occupies not too high a share, inferior to a similar indicator of developed countries, which contributes to the practice of buying highly productive animals, etc. abroad, although there is rich experience in the field of national breeding [18, c. 19].

The Chechen Republic has the appropriate specialized agricultural machinery and elite planting material for the development of the agro-industrial complex. Agricultural lands are enriched with the necessary mineral fertilizers, pesticides are used, new vines are planted instead of old vineyards, fishery reservoirs are restored, and fish farms are supplied with special fodder. But there are still problems regarding the provision of mineral fertilizers, pesticides, new machinery and equipment, etc. in different farms.

It is worth recalling that in the republic of the Soviet period, not only natural-climatic and soil conditions were taken into account in the allocation of agricultural production, but also the needs of the actively developing industry in the region, the specifics of transportation links with the areas of consumption of products of this sector. Comparison of the structure of modern agrarian production in the region and the early 1990s indicates their cardinal difference. So, today almost no sugar beet, grapes, tobacco are produced for sale in the market, not such large volumes of fruit and berry production, while these productions in the late 1980s and early 1990s gave the budget of the plant growing industry good income [19, c. 128].

Financial sustainability and modernization in the agricultural sector are considered important components in the framework of the implemented republican program for the development of the agricultural sector and regulation of markets of agricultural products, raw materials and food. The necessary condition for solving this problem can be the existence of a legislative and tax system that ensures the effective development of regional agrarian production sectors, as well as the provision of material support from the authorities.

It should be noted that the different results of state support in Russian regions may indicate the need for an individual approach in their analysis. Taking into account the practice of agrarian policy in European countries, when the federal level establishes instruments of state support and a single regulation for their application, while the regions are given the opportunity to choose from them for themselves, it would be possible to avoid complications of the state support system, which are possible in the conditions of granting greater powers to the regions [20, c. 20].

It should also be noted that, despite the government's extensive work on the development of rural areas in the country, the problem of the shortage of professional personnel in rural areas is still unsolved. At present, the most able-bodied and educated residents of rural areas, mostly represented by young people aged 18 to 35, are massively moving to cities for employment, while less than 10% of graduates of agricultural educational institutions prefer to live in rural areas. As evidenced by the data of the survey, the main reasons for this phenomenon include the low quality of housing and often its absence, many people do not recognize work in rural areas as appropriate for themselves [21, c. 15].

A big role in various state programs for the development of Russian rural areas is assigned to non-agricultural employment in rural areas. More return on both labor and other resources of rural territories can be expected from rural enterprises of industrial type, thus allowing to consider the creation of such structures as an important direction to increase employment and remuneration of rural residents. Such structures can be both small and medium-sized industries, which are engaged in various trades; processing of agricultural products, also carry out their transportation and storage; related to the recreational sphere and construction of various facilities; develop rural tourism, etc. In the conditions of interaction of agricultural processes with industrial processes, there is a multiple increase in production efficiency, also throughout the year there is a smoothing of unevenness in the use of labor of agricultural workers due to a more rational use of all types of resources involved in production.

Non-agricultural production is increasing in rural areas throughout the world. For example, up to 40-45% of the income of the rural population living in Central and Eastern Europe came from non-agricultural sources [21, p. 14]. The amount of non-agricultural income received by farmers in the states belonging to the Organization for Economic Cooperation and Development has now begun to exceed the income from purely agricultural activities [21, c. 14].

Thus, the available demand in the labor market in rural areas is affected not only by employment in the agricultural sector, but also by employment that is not related to it. At the same time, despite a significant decrease in employment in the agricultural sector, this sphere remains the main one for rural residents regarding the application of their labor. For the development of rural areas it is also important to have an appropriate legislative component of the process of preferential crediting and financing of rural companies of industrial type; to give them an opportunity, based on the industry specifics, not to pay taxes during the first 3-5 years of their activity, and later to pay them at the rate of 7-8%. It is also necessary for the state to insure the property of the participants of this process, as well as their personal funds and savings; to give them orders; to transfer the necessary production technologies, fixed assets and ownerless premises to them; to simplify the procedures related to the registration of relevant documents, etc.

Abstract

The article is devoted to the study of the basic principles of forming sustainable development projects at enterprises, establishing cooperation between business entities and financial and credit institutions in order to ensure effective achievement of the goals of sustainable transformations of the state. The object of the study is the substantiation of methodological and applied recommendations for the creation of a special fund-intermediary between enterprises and financial and credit institutions for conducting scientific, technological and environmental preparation of production. Formation of projects for sustainable economic development by enterprises requires an integrated approach and should begin already at the stage of forming an innovative idea. The formation of a stage of scientific, technological and environmental preparation of production for enterprises conducting work on developing innovative projects is proposed.

Keywords: sustainable development, cooperation, business entities, innovation, environmental responsibility

I. Introduction

The environmental situation not only in our country but also throughout the world has worsened at the end of the 20th century so much that with the beginning of the 21st century the world's leading countries are forced to seek opportunities to influence all business projects to ensure environmental safety. Moreover, we are talking about achieving sustainable development, when, without giving in to competition in various markets, companies will implement environmentally friendly measures in the technological direction. The problem of ecology is an important aspect of the survival of each nation. In order to ensure normal environmental and economic living conditions for people, the concept of sustainable development was, as is known, developed, which has been tried to be implemented in most countries of the world for several decades.

As for sustainable development, domestic enterprises have only recently begun to pay attention to it. To a certain extent, this was not facilitated by various factors related to the peculiarities of the domestic economy. Recently, the problem of the pandemic has been added to the negative factors, that is, management has to not only ensure sustainable development, but also respond to people's requests for job preservation. The economic conditions for the functioning of enterprises were also not such as to force them to work towards solving environmental problems. The economy of enterprises was under pressure: tax, administrative, under the threat of bankruptcy. Environmental requirements were hardly considered significant when citizens simply needed to work to earn money to support their families. Thus, the main areas of activity of enterprises in previous decades were the production of products (services) at any price, making a profit and surviving in unfamiliar market conditions of competition.

Research on sustainable development covers the interaction of business and government, manufacturing enterprises and financial and credit institutions. Undoubtedly, world experience is extremely useful in terms of the results already obtained. At the same time, the results of research by domestic scientists best reveal the causes, factors and consequences of the implementation of various environmental measures in the conditions of the domestic economy.

The study of the problem of interaction between business and government bodies has long attracted the attention of scientists, entrepreneurs, officials at all levels, and most importantly, the public to issues of social responsibility of business. In our country, the aspect of corporate social responsibility in the scientific and practical plane has only recently begun to receive due attention. In particular, among the scientists who studied the role of human potential in the context of sustainable development, institutional mechanisms for reducing the negative impact on the environment, modern areas of corporate social responsibility should be named S.S. Ovsyannikova [5], V.M. Gilmundinova [1], T.O. Tagaeva [1], T.V. Divina [2]. Separately, it is necessary to highlight the researchers who raised the issue of banking responsibility in the process of sustainable development. These include, in particular, A.I. Osipova [6], etc. Among foreign publications devoted to sustainable development in recent years, one can highlight the work "Implementation of social projects in the context of digital transformation of the banking sector" [6]. According to the study, the author relies on the perspectives of the interest of national and international organizations in creating favorable conditions for sustainable development. He emphasizes the fundamental role of the financial system in mobilizing capital for a green economy.

The purpose of the study is to determine the organizational form of cooperation between financial and credit institutions and enterprises in the context of bilateral compliance by the parties with the requirements of sustainable development, environmental responsibility to society. It is important to justify the creation of an appropriate financial fund at enterprises or a separate fund operating for enterprises, which will accumulate the enterprises' own funds and receive the necessary loan funds for the implementation of sustainable development measures by enterprises.

II. Methods

Dialectical method and methods of analysis and synthesis - to study the features of the implementation of innovative work at the stage of scientific-technological-environmental preparation of production in the formation of sustainable development projects; structural-logical analysis - to develop theoretical and methodological principles for the functioning of the fund to ensure cooperation in financing sustainable development projects.

Sustainable economic development presupposes such changes in the technological re-equipment of production that will not affect the environment and will not have negative impacts on human life, and will not interfere with life and reproduction of the natural environment. To ensure these requirements, the world community has adopted a number of international agreements, to which our country has also acceded.

III. Results

One of the leading areas of sustainable development is the preservation of the environment, which is most affected by man-made factors, and their sources are industrial enterprises. The implementation of measures aimed at changing production flow charts taking into account the requirements of sustainable development undoubtedly requires significant financial resources. It is well known that enterprises themselves are not able to provide financial support for environmental protection programs. They perceive expenses on environmental protection measures as a diversion of working capital and the creation of prerequisites for a decrease in solvency. They need appropriate funds, which can be obtained, including through loans from banks or para-bank institutions. Instead, a problem usually arises, consisting in the unprofitability of environmental protection measures. Only a change in the production apparatus (equipment, composition of raw materials and materials, etc.) can simultaneously serve to generate profit and protect the environment.

The problem of preserving the human habitat is important for both current and future generations. Therefore, it is necessary to find a way out, for which it is worth paying attention not only to environmental protection measures, but also to replacing technological schemes. To protect against harmful emissions, there is no alternative to the need to implement treatment facilities, all kinds of filters, aerators, etc. However, the first direction is really unlikely to ever directly serve as a source of repayment to credit institutions. The second direction - lending for the technological process taking into account environmental protection requirements - can ensure profit and in this direct way serve as a source of funds for settlements with creditors. The specified directions of action to protect the natural environment require further research, including the search for some balance between them.

To find and solve the problem under study, the idea of creating a special fund between enterprises and financial and credit institutions for conducting scientific, technological and environmental preparation of production should be useful. Each enterprise that carries out work on developing innovative projects, and therefore organizes the preparation of production, should form a corresponding fund for the implementation of environmental measures, which should be responsible for the quality of product design projects and production flow charts that will guarantee environmental safety on the part of the enterprise. Such a fund, created directly at the manufacturing enterprise, would be an accumulator of funds received for the development of technologies taking into account the requirements of sustainable development. Accordingly, such a fund should act on behalf of the enterprise with the initiative to obtain the necessary credit resources and enter into relations with commercial banks. Fund employees should cooperate with credit institutions in order to obtain the necessary loans.

Of course, doubts may arise regarding the advisability of creating such a fund directly at the enterprise. Features of the technological process, other special factors in the vertical form of cooperation of the enterprise within the holding or financial-industrial group may testify in favor of this proposal. In the conditions of the horizontal form of cooperation, it is possible to assume the creation of a separate venture fund, which will work for a group of enterprises similar in technological scheme. Then the allocation of a venture fund will be justified. Having chosen a certain version of the technological scheme for one enterprise, the fund can subsequently find opportunities to improve the technology and gradually offer new versions of more environmentally advanced technological processes to other enterprises of the group. Instead, the venture fund should not necessarily be limited to the funds provided by the enterprises. Moreover, the search for the best options for technological processes will force the attraction of credit resources.

From the standpoint of the participation of individual credit institutions and their entire aggregate in lending to manufacturing enterprises, the environmental responsibility of the banking system should be considered in several dimensions.

Traditionally, the focus of scientific research is on the issue of environmental responsibility at the expense of manufacturing enterprises. In this context, researchers pay attention, first of all, to the prevention of harmful effects of manufacturing activities on the environment, the introduction of environmentally friendly technological processes, and thirdly, to the production of products that would have the least impact on the environment. This impact is considered in several aspects: from the point of view of means of production and transport - the elimination or minimization of harmful emissions, in particular into the atmosphere (for example, the accumulation of liquid and gaseous emissions and their disposal, the production of electric cars, etc.); from the point of view of consumer goods - the production of products whose residues are easily dissolved by natural factors (for example, replacing polyethylene bags with paper, hard plastics for the production of stationery with cardboard, etc.). The examples given are well-known and have already been sufficiently implemented in production. At the same time, there are significantly more environmentally friendly measures at enterprises, especially taking into account global experience.

V. Discussion

The development of production based on innovation necessarily implies the attraction of credit resources, which directly requires cooperation with credit institutions. In other words, credit institutions also participate in the process of sustainable development, perhaps indirectly, when it comes to the implementation of innovative technological processes, new types of goods or services. The indirect nature of the participation of credit institutions is determined only by the fact that they do not work directly on product and technology projects. This is done by the relevant design and engineering and technological institutes, bureaus and directly by the manufacturers' enterprises.

Of course, the question arises regarding the quality of the used material and technical resources and future products from the point of view of environmental safety. As practice shows, it is no less important for the creditor than for the enterprise-manufacturer of the products to know the prospects for the sales of goods, services, real estate, etc. After all, the return of the loan and the payment of interest on it, which constitutes the profit of the credit institution, will depend on how successful the production and sale of these objects will be. The need to conduct an environmental audit of credit activities is emphasized, in particular, by the authors of [4].

The solution to this problem should be facilitated by appropriate cooperation between manufacturing enterprises and credit institutions, subject to environmental responsibility. An important stage of this cooperation should be scientific, technological and environmental preparation of production. Design of new products and technologies occurs precisely at the stage of scientific and technological preparation. An environmental component should be added to the development of designs and technologies in the technical and economic aspect. That is, in the process of working on the design, when the composition of materials for the future product, the efficiency of future machines, devices, equipment are determined, it is necessary to conduct examinations for harmfulness not only in the production process, but also in the process of operation, and later - during the disposal of used production tools.

It is necessary for creditors to understand the very content of the process of designing products and technologies, which should serve as a guarantee for the provision of loans not only for serial production of products, when the receipt of profits by both the borrower - the enterprise, and the creditor - the bank is quite clear and fast.

In order to organize proper interaction between a credit institution and an enterprise, it is necessary for the enterprise to create a separate fund-intermediary for scientific, technological and ecological preparation of production under the department of production preparation. The fund should be subordinated to the linear-technical director (chief engineer), and functionally - to the director of economics and finance. Such dual subordination is aimed at effective technical management, when all technical decisions are made by a manager who is well versed in the technological schemes used at the enterprise. The technical director is the specialist who, even at a large enterprise with a significant number of production units located at various territorially isolated sites, knows the specifics of the functioning of each section and their needs for innovative solutions. The director of economics and finance is knowledgeable in the field of functioning of the financial resources that the said fund should accumulate, should influence the financial component of technical solutions. Decisions on the use of the fund's resources should be made jointly by the two directors together with the head of the production preparation department as the initiator of the innovation and the fund manager as the person responsible for the effective use of financial resources. If it is necessary to conduct an environmental assessment, in particular in projects for treatment facilities, the bank may propose to involve in the assessment an appropriate environmental institution that has a license to conduct such an assessment and provide the relevant conclusion.

In conclusion, it is worth emphasizing the importance of establishing cooperation between enterprises and financial and credit institutions in the process of ensuring the implementation of the country's sustainable development strategy. Since the implementation of the foundations of sustainable transformations requires significant funding, the effective implementation of sustainable development programs by business entities is impossible without established cooperation with financial institutions.

In addition, it is also worth noting that the formation of sustainable economic development projects by enterprises requires a comprehensive approach and should begin already at the stage of forming an innovative idea. Thus, it is proposed to form a stage of scientific and technological environmental preparation of production for enterprises working on developing innovative projects. It is also important to create a fund that should become an intermediary between enterprises and financial and credit institutions for financial support for the implementation of scientific and technical preparation of production.

Abstract

Digitalization and smart technologies play a decisive role in the transformation of the economy towards sustainable development at the regional level. The article analyzes the impact of digital tools such as the Internet of Things (IoT), big data, artificial intelligence and automation on increasing the efficiency of natural and economic resources. The use of these technologies allows for the creation of smart cities and sustainable infrastructure, ensuring the optimization of energy consumption, reducing CO_2 emissions and improving the quality of life of local populations. Particular attention is paid to areas where digitalization has the greatest impact on sustainable development: transport, energy, utilities and waste management. The article considers specific examples of the implementation of smart solutions, such as smart lighting systems, environmental monitoring, intelligent traffic management, which helps reduce costs and increase the economic sustainability of the region. In addition, the mechanisms of interaction between business and the state in the process of implementing digital solutions, as well as the impact on the creation of new jobs and strengthening the competitiveness of regions are studied. The analysis highlights that digitalization not only contributes to increased efficiency, but is also becoming an important factor in the formation of a sustainable and competitive economy capable of adapting to modern challenges and global changes.

Keywords: sustainable development, digitalization, smart technologies, regional economy, sustainable economic growth, Internet of things, artificial intelligence

I. Introduction

In recent years, sustainability has emerged as a core objective in regional development, driven by the recognition that economic growth must be balanced with environmental protection and social well-being. As global environmental pressures, such as climate change, resource depletion, and pollution, continue to intensify, regions are increasingly exploring innovative solutions to build resilient and sustainable economies. Digitalization and smart technologies have proven to be powerful tools in this transition, offering unprecedented ways to optimize resource use, reduce environmental impacts, and improve public services.

Digitalization, encompassing technologies like the Internet of Things (IoT), big data analytics, artificial intelligence (AI), and blockchain, is enabling regions to modernize key industries and infrastructure. IoT, for example, allows for real-time monitoring and management of resources, from energy and water to waste, contributing to more efficient systems and lower operational costs. AI and big data, meanwhile, provide actionable insights for better decision-making, helping governments and businesses predict demand, manage supply chains, and reduce waste. Through these advancements, digitalization supports the development of "smart" cities and communities—

places that actively use technology to manage resources responsibly, mitigate emissions, and promote sustainable lifestyles.

A major area of impact is energy management, where smart technologies, like renewable energy grids and smart meters, allow for precise control over energy production and consumption. These innovations enable regions to rely more on renewable sources, such as solar and wind, which can be integrated into existing grids to reduce dependency on fossil fuels and cut greenhouse gas emissions. In the transportation sector, smart systems improve traffic flow, optimize public transit, and reduce emissions, while in agriculture, digital tools aid in precision farming, optimizing water use, and minimizing chemical inputs. Each of these advancements contributes to building a regional economy that is both economically viable and environmentally sustainable.

However, the transition to a digitally driven, sustainable economy is not without challenges. Successful implementation requires coordinated efforts among government entities, private sector actors, and local communities. Investment in digital infrastructure and skills training is essential, as is the establishment of regulatory frameworks that ensure data security and privacy. Moreover, digitalization raises questions about social equity, as technology access and literacy vary significantly across different demographic groups. This digital divide must be addressed to ensure that sustainable development benefits are widely accessible.

II. Methods

To investigate the role of digitalization and smart technologies in promoting sustainable regional economic development, this study adopts a mixed-methods approach, combining quantitative data analysis, case studies, and expert interviews. This multi-dimensional methodology provides a comprehensive view of how digital technologies impact regional sustainability across various sectors, such as energy, transportation, waste management, and public services. Below is an outline of the specific methods used.

1. **Quantitative Data Analysis**

Quantitative data was collected from regional government databases, environmental agencies, and public economic records to measure key indicators of sustainability and economic impact. Indicators include energy consumption, greenhouse gas emissions, operational efficiency metrics, and cost savings attributed to the use of digital technologies. Statistical analysis was applied to examine correlations between technology adoption and improvements in these sustainability metrics, providing insight into the direct and indirect effects of digital solutions.

2. **Case Studies of Smart Technology Initiatives**

Case studies were selected from various regions that have successfully implemented smart technologies in key sectors. Each case study provides an in-depth analysis of specific projects, such as smart grid integration, IoT-based water management, and AI-powered public transportation systems. The case studies document the processes of project implementation, including the selection of technologies, stakeholder collaboration, financing, and regulatory support. Data from these cases helped to identify patterns, challenges, and best practices in leveraging digitalization for sustainable development.

3. **Expert Interviews and Surveys**

To understand the practical and strategic implications of implementing digital solutions, semi-structured interviews were conducted with experts from government agencies, tech companies, environmental organizations, and academic institutions specializing in regional development and sustainability. These interviews gathered insights on challenges in implementation, the role of policy, and the socioeconomic impacts of digital transformation on regional sustainability efforts. Surveys were also distributed to industry professionals to collect broader perspectives on the barriers and opportunities of digitalization in sustainable development.

4. **Comparative Analysis of Regional Digital Transformation Policies**

A comparative policy analysis was conducted to evaluate the role of government policies in driving digital and smart technology adoption for sustainable regional development. Policy documents, strategic frameworks, and government reports from regions with differing levels of digitalization were analyzed to assess the effectiveness of incentives, regulations, and public-private partnerships in fostering sustainable practices. This comparative approach helped to highlight the role of policy in overcoming challenges such as funding constraints, digital infrastructure needs, and technology literacy gaps.

5. **Impact Assessment Model**

Based on the findings from the quantitative analysis, case studies, and interviews, an impact assessment model was developed to evaluate the economic and environmental effects of digitalization across different sectors within regional economies. This model considered both direct impacts, such as cost savings and emission reductions, and indirect impacts, including job creation and social equity improvements. The model provided a framework for estimating long-term sustainability benefits and challenges associated with digitalization, offering a holistic view of its role in regional sustainable development.

By integrating these methods, this study presents a well-rounded analysis of how digitalization and smart technologies contribute to sustainable economic development at the regional level, identifying key success factors, limitations, and opportunities for scaling these initiatives.

III. Results

Digitalization plays a crucial role in enhancing the effectiveness and efficiency of cities concerning planning, management, and development. The ongoing digital transformation has revolutionized the business ecosystem, altering the value chain processes across various industries. This transformation presents a wealth of opportunities through the application of technologies and intelligent systems that offer smart solutions to urban challenges. Digitalization encourages innovation by fostering a collaboration between physical and digital realms among stakeholders within urban contexts and beyond.

In a broader sense, digital technologies significantly accelerate access to data and knowledge, thereby enhancing institutional accountability, improving the efficiency of scientific endeavors, and promoting innovation across numerous sectors. These data-driven technologies are pivotal in the development of smart cities, enabling the resolution of urban issues and facilitating better decision-making to elevate the quality of urban life. A smart city comprises an integrated system of six components: smart people, smart living, smart mobility, smart environment, smart economy, and smart governance. The effectiveness of these components can be further enhanced through the application of several key technologies, including Information and Communication Technology (ICT), the Internet of Things (IoT), sensor technology, geospatial technology, Artificial Intelligence (AI), and Blockchain.

ICT serves as the primary technology in smart cities, implementing smart initiatives through the integration of physical infrastructure and data processing tools. IoT devices enable cities to gather and analyze real-time data, helping to identify problems and improve service delivery. In the smart city framework, sensor technology measures various system metrics, including energy consumption, water quality, gas usage, traffic congestion, and pollution levels. AI technology is utilized to manage and control automated city infrastructures, while geospatial technology is applied across smart city subsystems—such as energy, transportation, public services, and governance—to enhance infrastructure management efficiency. Additionally, Blockchain technology provides a secure communication framework within the smart city.

While digital technologies are expected to improve the quality of life for individuals and communities, it is crucial not to overlook their environmental costs. Therefore, promoting the development of cyber-physical assets in conjunction with sustainability considerations is essential. This approach not only aims to enhance citizens' quality of life but also seeks to improve the overall urban environment. It is vital to ensure that the utilization of digital technologies contributes to long-term well-being across economic, social, and environmental dimensions.

In today's Information Society, the adoption and integration of smart technologies are increasingly driving growth and competitiveness, particularly within the realm of regional policy. The rapid evolution of digital technologies and Information and Communication Technologies (ICTs) has introduced significant challenges to achieving smart, sustainable, and inclusive growth, aligning with the objectives of the Europe 2020 strategy. A crucial aspect of this transformation is the ability to adapt digital tools and entrepreneurial strategies to the unique conditions of each region, thereby fostering knowledge-based innovation, setting clear priorities, and enabling informed decision-making.

As the adoption of ICT becomes central to national and regional policies, governments worldwide are formulating digital development strategies aimed at enhancing efficiency and transparency in public administration, stimulating innovation and entrepreneurship, and improving the overall quality of life. These new technologies are facilitating a shift toward a digital economy, which not only creates value-added opportunities but also contributes to economic growth in various dimensions.

For policymakers, it is vital to connect the penetration of ICT within companies and the development of relevant infrastructure with key economic outcomes such as job creation, improved competitiveness, and increased export activity. Investments in ICT, the enhancement of workforce digital skills, the promotion of demand-driven innovation from the public sector, and the reform of the regulatory framework are expected to serve as growth drivers at local, regional, and national levels, provided that they are supported by appropriate policies.

The focus of this study is on the role of smart technologies in regional development, specifically through the lens of the regional innovation system model. Innovation is not merely an isolated act within a single organization; it is embedded in a larger system that facilitates and enhances the innovation process. These processes are critical for the effective application of new technologies and the promotion of knowledge-sharing.

According to Lundvall, innovation systems are open, social, and dynamic. They are considered open because innovations emerge from interactions among various economic actors, meaning they are responsive to external influences. They are social because they are grounded in an institutional environment shaped by laws, social norms, cultural models, and technical frameworks. They are dynamic due to ongoing financial exchanges between public and private organizations, talent flows among universities, corporations, and government agencies, and regulatory influences from government bodies to innovation agencies. Innovation systems can be analyzed at several levels, including sectoral, regional, national, and international.

Regional Innovation Systems are typically composed of a network of private, semi-private, and public entities that operate within an institutional framework designed to encourage knowledge creation, transmission, and application. Research on Regional Innovation Systems has identified three primary dimensions: the interactions among innovation system actors for knowledge exchange, the role of institutions in supporting regional knowledge-sharing and innovation, and how Regional Innovation Systems influence regional innovation policies. According to Autio, the Regional Innovation System consists of five main dimensions:

1. A subsystem focused on the application and exploitation of knowledge through innovative industries and companies,
2. A subsystem for knowledge production and dissemination that includes higher education institutions and research centers,
3. High-intensity interactions between subsystems involving scientific and applied knowledge and human resource flows,

4. A robust infrastructure and institutional framework, with significant regional autonomy, and
5. Active regional policy actors who guide and support regional innovation initiatives.

Understanding the dynamics within regional innovation systems and the impact of smart technologies on regional economic development is essential for formulating effective strategies that lead to sustainable growth.

IV. Discussion

The integration of digitalization and smart technologies in urban environments has profound implications for enhancing the quality of life and the efficiency of city management. As cities continue to evolve into smart cities, it is essential to critically evaluate the multifaceted impact of these advancements. This discussion explores key themes related to the benefits, challenges, and future directions of digitalization in urban settings.

Enhancing Urban Efficiency and Quality of Life

Digitalization has transformed the way cities operate, leading to improved efficiency in service delivery and resource management. The adoption of technologies such as the Internet of Things (IoT) enables cities to collect real-time data, which can be used to optimize services such as waste management, public transportation, and energy consumption. For instance, smart traffic management systems can analyze traffic patterns and adjust signals in real-time, reducing congestion and emissions while enhancing mobility. These efficiencies contribute to a higher quality of urban life by making cities more livable and accessible.

Moreover, smart technologies facilitate greater citizen engagement and participation in governance. Through digital platforms, residents can access information, voice their concerns, and engage in decision-making processes. This transparency fosters trust between citizens and local governments, leading to more responsive and accountable governance. Enhanced communication frameworks, supported by technologies like Blockchain, can further improve data integrity and security, ensuring that citizens' information is handled responsibly.

Driving Innovation and Economic Growth

Digitalization also stimulates innovation and economic growth in urban areas. By creating a conducive environment for startups and tech firms, cities can become hubs of innovation that attract talent and investment. The emphasis on knowledge-based economies encourages collaboration among universities, research institutions, and businesses, driving advancements in various sectors.

However, the growth of a digital economy must be approached thoughtfully. The focus on technological innovation should be accompanied by policies that ensure equitable access to digital resources. This includes investments in digital infrastructure and education to improve digital literacy among all residents, particularly marginalized communities. Failure to address these disparities may exacerbate existing inequalities, hindering the overall benefits of digitalization.

Addressing Environmental Concerns

While the potential benefits of digitalization are significant, it is imperative to address the environmental costs associated with these technologies. The production and disposal of digital devices contribute to electronic waste, and the energy consumption of data centers raises concerns about sustainability. Therefore, integrating sustainability principles into digital strategies is crucial.

Cities should prioritize the development of cyber-physical assets that not only enhance urban efficiency but also promote environmental sustainability. This can include the implementation of green technologies, energy-efficient infrastructure, and sustainable urban planning practices. For

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

instance, the use of smart grids can optimize energy distribution and integrate renewable energy sources, reducing reliance on fossil fuels and lowering carbon emissions.

Future Directions

Looking ahead, the successful integration of digitalization in urban environments will depend on a holistic approach that considers social, economic, and environmental factors. Policymakers must develop frameworks that encourage collaboration between public and private sectors, ensuring that digital initiatives align with broader sustainability goals.

Investments in research and development should focus on emerging technologies that have the potential to enhance urban life while minimizing environmental impact. Furthermore, continuous evaluation and adaptation of digital strategies will be essential in response to the evolving needs of urban populations and the challenges posed by climate change.

In conclusion, while digitalization and smart technologies offer significant opportunities for enhancing urban living, a balanced approach is necessary to ensure that these benefits are realized in an equitable and sustainable manner. By addressing the challenges and leveraging the potential of digitalization, cities can create resilient urban environments that improve the quality of life for all residents.

The transition toward Smart Sustainable Cities (SSCs) is significantly influenced by the implementation of innovative technologies. While these technologies offer promising benefits, they also pose notable environmental and social challenges. The following discussion explores both the advantages and the drawbacks of digital technologies in urban contexts, highlighting the need for a comprehensive evaluation framework to assess their net impact.

Advantages of Digital Technologies in Smart Sustainable Cities

Digital technologies such as Artificial Intelligence (AI), Internet of Things (IoT), and big data analytics play a pivotal role in enhancing urban environments. The table below summarizes the key benefits associated with these technologies:

These technologies collectively enhance the efficiency of public services, reduce greenhouse gas (GHG) emissions, and improve citizens' quality of life by enabling better resource management and decision-making. They also facilitate greater citizen engagement in governance, promoting transparency and accountability within urban administrations.

Environmental and Social Risks Associated with Digital Technologies

Despite the benefits, the application of digital technologies in urban environments can lead to significant environmental and social challenges. The following outlines some key risks:

Environmental Risks:

1. High Energy Consumption: Many digital technologies are energy-intensive, leading to increased GHG emissions.
2. Pollution from Connected Devices: The proliferation of IoT devices can contribute to environmental pollution.
3. Exploitation of Rare Earths: Increased demand for technological devices results in the depletion of rare earth materials and the use of plastics, which are difficult to recycle and contribute to environmental degradation.
4. Difficulties in Recycling: The end-of-life phase of technological products poses challenges for recycling raw materials, exacerbating environmental issues.

Social Risks:

1. Privacy Concerns: The use of AI and IoT can compromise citizens' privacy when personal data is processed without consent.
2. Data Governance Issues: The complexity of new technologies often leads to the delegation of data governance to private entities, raising concerns about oversight.
3. Cybersecurity Risks: Increased reliance on digital technologies heightens the risk of cyberattacks, endangering data protection.

4. Discrimination and Marginalization: The implementation of new technologies may inadvertently marginalize older populations or those in rural areas, limiting their access to digital services.

These environmental and social risks pose significant challenges to the development of truly sustainable smart cities.

Table 1: *The key benefits associated with these technologies*

Technology	Description	Benefits for SSC Development
AI	Training of AI systems	- More efficient resource utilization for public services - Reduced consumption and emissions - Pollution level monitoring and targeted policy support - Enhanced provision of essential public services (e.g., healthcare, transportation)
Big Data Analysis	Collection and analysis of large urban data	- Prediction of environmental catastrophes - Data-driven initiatives against environmental events - Optimization of decision-making based on citizen needs - Effective public fund allocation
Data Platform	Real-time analysis and control of urban data	- Real-time monitoring of environmental conditions - Prompt disaster response - Support for decision-making activities - Enhanced citizen participation in governance
IoT	Sensors and intelligent devices	- Real-time interaction and monitoring of urban environments - Measurement of air pollution - Small-scale renewable energy production - Improved public services and security
ICT	Digital infrastructures for communication	- Reduced information transmission times - Quick emergency responses - Widespread network access - Democratization of technology and reduction of the digital divide

Evaluating the Net Impact of Digital Technologies

To effectively assess the net impact of digital solutions on the development of Smart Sustainable Cities, a risk assessment framework is essential. This evaluation should consider two scenarios for social risks:

1. Best Scenario: Implementation of all countermeasures by Public Administration to mitigate risks.

2. Worst Scenario: Failure to implement necessary remedies, leading to exacerbated risks.

For environmental risks, a quantitative approach is recommended, utilizing existing literature to gauge the potential harm caused by each technology. The impact of each solution can be measured on a scale from 1 (significantly positive impact) to 5 (significantly negative impact). The overall effect on the urban ecosystem can then be calculated as the sum of these values.

Conclusion

The path toward developing Smart Sustainable Cities is paved with opportunities and challenges posed by digital technologies. While the benefits are substantial, the potential environmental and social risks necessitate careful evaluation and proactive management. A comprehensive risk assessment framework, coupled with strategic policy interventions, is vital for ensuring that the transition to smart cities enhances urban sustainability while safeguarding the rights and well-being of all citizens. By addressing these risks thoughtfully, cities can realize the full potential of digital technologies in fostering sustainable urban environments.

Abstract

The article deals with the possibility of reducing the food security risks by creating optimal conditions for plant growth and development in accordance with climatic conditions. To do this, it is necessary to know the evapotranspiration of plants for the studied period of times. On the example of the study of on apple's seedlings evapotranspiration depending on meteorological and biological conditions under different watering schedule with drip irrigating in central region of Russia, the obtained regression equations for definition of evapotranspiration are given.

Keywords: resource-saving technologies, risk, food security, evapotranspiration, differentiated irrigation schedule, drip irrigation, apple seedlings, irrigation rate

I. Introduction

The Decree of the President of the Russian Federation "On the approval f the Doctrine of food security oa the Russian Federation" is indicated that ensuring the country's food security involves risks that can significantly affect it.

With the existing climate change, which is characterized by global instability, new risks are emerging in all areas of human activity and, as a first - in agriculture. This is due to increasing frequency of hurricanes, floods, and droughts, which can lead to a sharp decrease in gross output or complete loss, which is directly related to the risk of food security. One of the mechanisms for managing climate risks is to maintain an optimal water-air regime of the soil during the crop's cultivation throughout the growing season in accordance with the changing requirements of plants according to the phases of their development.

Resource-saving technologies aimed at rational nature management and environmental protection play an important role in such conditions, which ensure the saving of irrigation water, protection of soils, as well as surface, groundwater and water resources from pollution. A scientifically based irrigation regime developed in accordance with plant water requirements, as well as rational irrigation techniques meet the principles of resource saving.

The main indicator used in the justification of irrigation schedule is the evapotranspiration of crops, which serves as a measure of the moisture need of plants. This indicator allows determining the irrigation quantity and rate in specific condition and therefore this is the basis of plants water management. There are experimental and calculated methods of evapotranspiration determination [2,3,4].

Evapotranspiration, or total water consumption, is a function of external and internal factors. External factors include meteorological conditions, the level of agricultural technology, soil moisture; internal factors include the physiological characteristics of the plant (type and phase of development). With optimal moisture reserves in the soil, evapotranspiration is more dependent on the temperature regime of the external environment and the influx of solar radiation, that is, it has a bioclimatic character [1, 14].

During the growing season, evapotranspiration changes in accordance with the changing requirements of plants to the water regime due to the passage of different phases of development, as well as meteorological conditions. The greatest intensity of evapotranspiration is observed when the periods of maximum plant water demand coincide with the most intense meteorological conditions [1,3,12].

Since evapotranspiration largely depends on the type of crop, the phase of its development, and growing conditions, it is necessary to determine its values experimentally for certain types of crops grown in various soil and climatic conditions over the required period of time [13]. It is especially important to know the daily water consumption of a crop with drip irrigation, which makes it possible to accurately regulate soil moisture and maintain it within the required limits for a given crop throughout the growing season. In this case, the irrigation rate for drip irrigation should correspond to evapotranspiration for a certain period, which will allow maintaining soil moisture in the required range.

The existing methods for determining evapotranspiration are divided into experimental (direct measurement methods) and computational methods based on establishing the relationship of water consumption with climatic and biological factors [14]. Experimental methods make it possible to obtain the most accurate result, but are characterized by high labor intensity and low efficiency, which is due to the influence of many external and internal factors. It is the great variability of evapotranspiration over time and in accordance with natural and climatic conditions that has led to the creation of a large number of computational (empirical) methods. To be able to use computational methods, it is necessary to experimentally obtain additional coefficients or coupling equations that correspond to specific conditions and the cultivated crop.

II. Materials and methods

As a result of studies of the water regime of apple seedlings grown under drip irrigation in the conditions of the Moscow region under various irrigation regimes, the values of evapotranspiration of seedlings for three years with different availability of temperature and precipitation were obtained.

In the nursery of the Michurinsky garden of the Russian State Agricultural Academy named after K.A.Timiryazev in 2011-2013, studies were conducted on the formation of seedlings of apple trees White infusion and Honeydew under various irrigation regimes. The following humidification regimes were studied: option I – soil moisture was maintained in the range of 70-95% HB; II – humidity was maintained in the range of 60-85%HB; III variant is differentiated – in the first year of sapling development, humidity was similar to option I, and in the next two years, similar to option II; IY variant (control) – without irrigation [7]

The soils of the pilot area are sod-podzolic on the cover loam, medium loamy. Watering was carried out by drip lines arranged according to the scheme 0.9x0.3m with built-in droppers with an auto-compensation system, which made it possible to maintain a constant flow rate of 3.8 l/h droppers. The moisture layer changed over the years in accordance with the depth of development of the root system. In the first year it was 30cm, in the next two years it was 40 and 50 cm. Soil moisture was determined using tensiometers, the readings of which were compared with the humidity determined by the thermostatic-weight method.

Evapotranspiration of apple seedlings was calculated based on changes in moisture reserves in the active soil layer. It is quite difficult to plan irrigation with drip irrigation according to the evaporometer data in humid regions, this is due to the uneven distribution of precipitation in time and space, which does not allow considering their effect on the available moisture content in the soil. In this regard, in humid areas, it is advisable to use a method for calculating water consumption based on measuring the actual soil moisture, which eliminates the need to consider the amount of precipitation [5]. Then evapotranspiration for the estimated period E will correspond to the difference in the values of moisture reserves in the soil at the beginning and end of the period under consideration (W_H-Wk) plus precipitation (P) and groundwater recharge (Vg)

Knowing the actual values of soil moisture, it is possible to calculate moisture reserves at the beginning and end of the decade and determine evapotranspiration using the water balance equation [3, 4, 6, 7, 8, 9, 10]:

$$W_k = W_н + P + Z - E \pm V_g,$$

где W_k и $W_н$ – moisture reserves in the soil layer at the end and beginning of the calculation period, m3/ha;

P – precipitation, m3/ha;

Z – condensation of water vapor during the calculation period, m3/ha, with a decadal calculation of soil moisture dynamics, condensation of water vapor is insignificant;

E – evapotranspiration, m3/ha;

Vg– groundwater recharge, m3/ha. (This value was insignificant due to the deep occurrence of groundwater and the light granulometric composition of the soil.

III. Research results

The obtained values of evapotranspiration of one-, two- and three-year-old apple seedlings for three years of different availability are shown in Table 1. The table data confirm the direct dependence of evapotranspiration on the degree of soil moisture: thus, the highest values were obtained in 2013, as the wettest, in all variants. Over 3 years of research, the maximum values were noted in the most humidified variant I, where evapotranspiration increases from 3,561 in 2011 to 4,239 m3/ha in 2013. The minimum values of evapotranspiration were obtained in 2012: in the II variant – 3068 m3/ha, in the III – 3056 m3/ha (soil moisture within 60-80% HB) and in the control – 2301 m3/ha. This is due to the fact that in 2011, in all variants, survival irrigation was carried out at a rate of 410 m3/ha, and 2012 was characterized by a lower amount of average daily temperatures, more precipitation and a lower inflow of total solar radiation.

Changes in evapotranspiration during the growing season are determined by both climatic factors and the phase of apple seedlings growing. The maximum value of evapotranspiration of annual seedlings was obtained in the 3rd decade of July: from 183 m3/ha to 355 m3/ha in accordance with variants. During this phase, the leaf surface area is still small, and moisture evaporates intensively from the soil surface. The second peak of evapotranspiration is observed in the 3rd decade of July, which is associated with the development of the maximum leaf surface area, which contributes to intensive transpiration against the background of high average daily temperatures and a large inflow of solar radiation.

It should be noted that the control variant, in which did not consider the first two decades of May in connection with engraftment irrigation. In 2012, the maximum water consumption was also noted in the 3rd decade of July: from 234 m3/ha to 382 m3/ha. In the third year of research, the greatest importance of evapotranspiration was in the 2nd decade of May, when a combination of high temperatures and an inflow of total solar radiation was observed. In addition, this period is characterized by an intensive growth of seedlings. It is necessary to pay attention to the III differentiated variant, where, compared with the I variant, water consumption for three years of research was 1519 m3/ha less, and the quality and yield of seedlings are the same as in the I variant [7]

After irrigation is stopped, evapotranspiration levels out in all variants and reaches minimum values.

Table 1: *Evapotranspiration of apple seedlings under various soil moisture conditions for one, two and three-year-old seedlings, m3/ha*

The general character of evapotranspiration dynamics for seedlings of the second year of growing is described by a polynomial trend line (Fig. 1). As can be seen from the figure, evapotranspiration, reaching its peak in the 2-nd decade of July, gradually decreases by the end of the growing season.

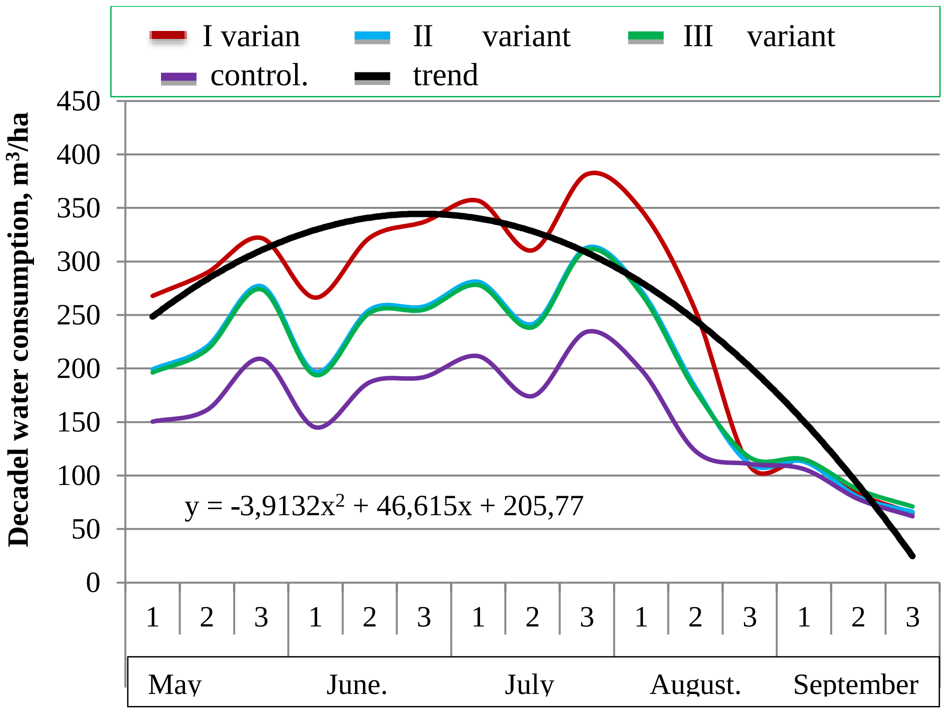

Figure 1: *Dynamics of decadal evapotranspiration of two-year-old apple seedlings described by a polynomial of the second degree*

IV. Discussion

During studies for three years of different security and seedlings of different ages, a linear dependence of evapotranspiration on such meteorological factors as the inflow of total solar radiation and the sum of average daily temperatures was established [11], which is described by the following regression equation (tab.2). In the equations under consideration E – evapotranspiration per decade, m^3/ha, t – sum of average daily temperatures per decade, Q – inflow of per decade, M j/m^2. It should be noted that these equations are valid only for the irrigated period. Evapotranspiration at the end of the vegetation is difficult to describe by these equations, as the average daily temperature, inflow of total solar radiation decreases significantly, and the amount of precipitation increases significantly.

On the basis of the obtained equations, a three-dimensional graph of the dependence of evapotranspiration on climatic factors for 1 variant of three-year seedlings according to the equation E=*7,4+0,81Q+0,91t* (*Fig*.2)

Table 2: *Dependence of evapotranspiration on the sum of average daily temperatures and inflow of total solar radiation*

Year	Experience option	Regression equation	Determination factor, R^2	Model error
2011	I (70–90% HB)	$E = -24{,}9 + 0{,}77t + 0{,}69Q$	0,89	± 4,4
	II (60–80% HB)	$E = -20{,}9 + 0{,}65t + 0{,}64Q$	0,83	± 0,5
	Control	$E = -10{,}2 + 0{,}46t + 0{,}29Q$	0,98	± 2,3
2012	I (70–90% HB)	$E = 30{,}2 + 0{,}76t + 0{,}73Q$	0,77	± 6,5
	II (60–80% HB)	$E = -42{,}3 + 0{,}64t + 0{,}86Q$	0,81	± 4,5
	Control	$E = -50{,}9 + 0{,}41t + 0{,}80Q$	0,74	± 2,5
2013	I (70–90% HB)	$E = 7{,}4 + 0{,}81t + 0{,}91Q$	0,89	± 0,5
	II (60–80% HB)	$E = 4{,}0 + 0{,}62t + 0{,}81Q$	0,92	± 2,9
	Control	$E = 1{,}3 + 0{,}44t + 0{,}63Q$	0,73	± 4,4

For annual apple seedlings, a general model for calculating evapotranspiration has been developed depending on the total solar radiation (Q), the sum of average daily temperature (t) and soil moisture (γ)

$$E = -101{,}3 + 0{,}62Q + 0{,}54t + 1{,}9\gamma \pm 11{,}4,\ R = 0{,}81.$$

The soil moisture parameter is set as follows: 70 - in the irrigation mode of 70-90% FC, 60 - in the irrigation mode of 60-80% FC and 0 - in the absence of irrigation.

Similar equations were obtained for two- and three-year-old seedlings, respectively.

$$E = -137{,}8 + 0{,}56Q + 1{,}09t + 1{,}5\gamma \pm 30{,}7,\ R = 0{,}74;$$
$$E = -56{,}6 + 0{,}62Q + 0{,}78t + 1{,}5\gamma \pm 20{,}8,\ R = 0{,}78$$

However, the best result was shown by a simple linear dependence of evapotranspiration on the total solar inflow radiation for 3 years of research on all irrigated variants (Tab.3, Fig.3)

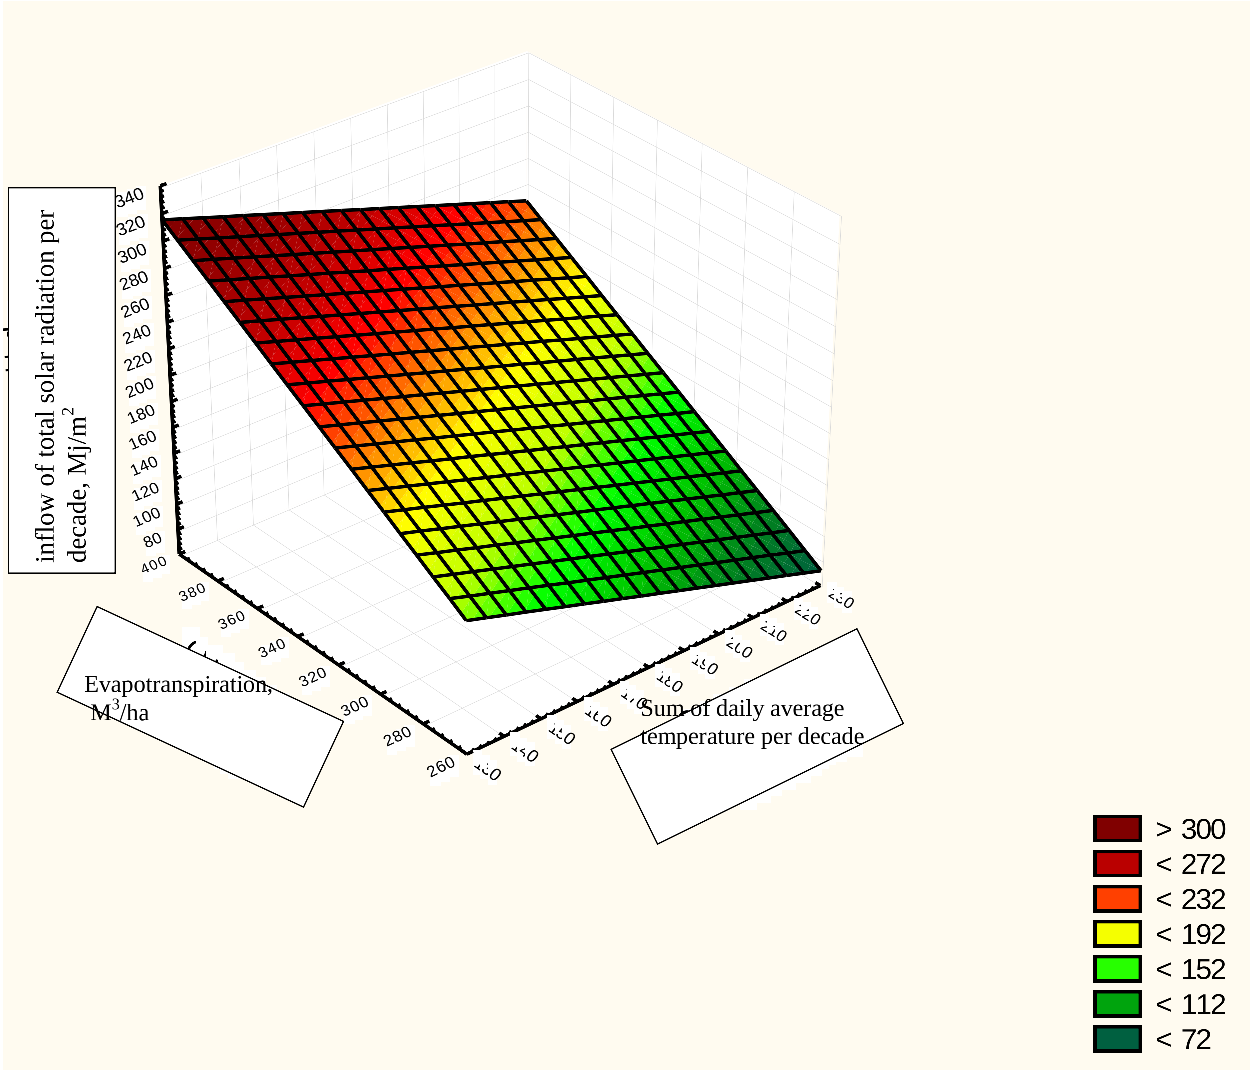

Figure 2: *Three-dimensional graph of the dependence of evapotranspiration on climatic factors for 1 variant of three-year seedlings*

Table 3: *Dependence of evapotranspiration (E) on the total solar radiation inflow (Q)*

Experience option/Year	2011	2012	2013
I	E=1,21Q+23,9 R^2=0,91	E=1,97Q – 81,7 R^2=0,87	E=1,68Q+14,49 R^2=0,94
II	E=1,00Q+37,9 R^2=0,91	E=1,48Q-48,3 R^2=0,91	E=1,31Q+26,1 R^2=0,95
III	E=1,21Q+23,9 R^2=0,91	E=1,21Q+23,9 R^2=0,91	E=1,31Q+25,3 R^2=0,94

The obtained equations allow to maintain soil moisture in accordance with required irrigation regime (tab.4) and the period of development of seedlings, as each equation is valid for a specific period. This is especially true for drip irrigation, when frequent irrigation norms mainly correspond to evapotranspiration over the past period (2 – 7 days), i.e.

$$m = E, \quad m^3/ha$$

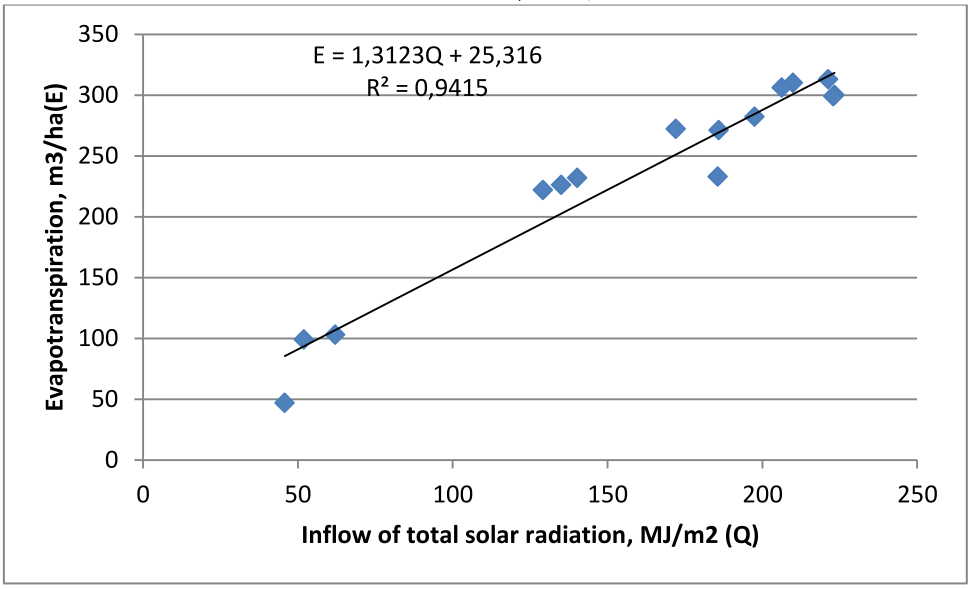

Figure 3: *Graph of the dependence of evapotranspiration (E) on the inflow of total solar radiation (Q)*

For maintenance the specified soil moisture ranges, the irrigation norm was: for 1 variant – 1665, 1481, 1463 m³/ha for years of research, for II variant 1362, 731,748 m³/ha, for III variant -1644, 725 and 741 m³/ha, respectively (Tab. 3). Irrigation water were regularly fed to the site with small norms, thus ensuring constant and uniform moisture of the active soil layer.

Table 4: *Comparative characteristics of different modes of irrigation of apple seedlings.*

Indicator	Experience options								
	I variant (70-90 % FC)			II variant (60-80 % FC)			III variant differentiated		
	Year of research								
	2011	2012	2013	2011	2012	2013	2011	2012	2013
M (irrigation norm, m^3/ha	1665	1481	1463	1362	731	748	1644	725	741
m (norm of watering,m^3/ha	41	49	59	41	46	58	40	45	57
Number of waters	41	30	25	33	16	13	41	16	13
T (The period between watering, day)	2	3	4	3	5	7	2	5	7

Irrigation norms increased annually in accordance with the increasing of roots zone from 30 to 50 cm and amounted to 40, 49, 58 m^3/ha years research respectively. The number of waterings depended on the experience and meteorological conditions of the year and varied from 16 to 30. The period between watering varied according to years of research and depending on soil moisture regime (experience options) from 2 to7 days, which ensured uniform moisture during drip irrigation.

V. Conclusions

1. Resource-saving technologies that contribute to reducing food security risks include the development of scientifically based §rational irrigation regime based on knowledge o plant evapotranspiration by development phases.

2. The maximum value of evapotranspiration during the vegetation period is typical for the most humid variant (1) – 3561,3828 and 4239 m^3/ha years of research, respectively, the minimum – for control (without irrigation) – 2301,2344 and 2777 m^3/ha. The highest values of evapotranspiration were recorded in the 2nd and 3rd decades of May (I variant - 355 -382 m^3/ha, II variant – 312 – 314 m^3/ha, control – 182- 244 m^3/ha)

3. Differentiated irrigation regime contributes to the saving of irrigation water, which in two years reached 777 m^3/ha, in three years - 1500 m^3/ha and decrease in evapotranspiration by 795 and 1519 m^3/ha, respectively.

4. Regression equations describing the dependence of evapotranspiration on the inflow of total solar radiation and the sum of average daily temperatures have been obtained, the use of which will allow to quickly manage the water regime of plants in accordance with changing climatic factors and resource saving requirements.

Abstract

Regional integration associations play a crucial role in promoting sustainable development across member states by fostering economic collaboration, social cohesion, and environmental sustainability. These organizations facilitate the exchange of best practices, harmonization of policies, and mobilization of resources to address common challenges such as poverty reduction, climate change, and social inequality. By implementing regional strategies and frameworks, these associations can enhance infrastructure development, improve trade and investment flows, and support sustainable resource management. Furthermore, regional integration promotes dialogue and cooperation among diverse stakeholders, including governments, businesses, and civil society, to create a shared vision for sustainable development. This paper examines the contributions of various regional integration associations, highlighting successful case studies and identifying key challenges and opportunities for enhancing their impact on sustainable development goals (SDGs). Ultimately, the findings underscore the importance of collaborative approaches in achieving sustainable development and emphasize the need for continued investment in regional integration initiatives.

Keywords: economic collaboration, social cohesion, environmental sustainability, resource management, trade and investment, sustainable development goals (SDGs)

I. Introduction

In an increasingly interconnected world, regional integration associations have emerged as vital entities in advancing sustainable development. These organizations—formed by countries within specific geographical areas—aim to foster economic cooperation, promote social inclusion, and address environmental challenges collectively. As globalization continues to reshape economies and societies, the role of regional integration becomes increasingly significant in facilitating cross-border collaboration and creating synergies among member states.

Regional integration associations encompass various forms, including economic unions, political alliances, and trade blocs, each tailored to the unique contexts and needs of their member countries. By establishing common frameworks and policies, these associations enhance collective action toward achieving the Sustainable Development Goals (SDGs), which were adopted by the United Nations in 2015 as a universal call to end poverty, protect the planet, and ensure prosperity for all by 2030.

The contributions of regional integration associations to sustainable development are multifaceted. They help streamline trade and investment, enhance infrastructure development, and promote sustainable resource management practices. Additionally, these associations facilitate knowledge exchange, enabling member states to learn from one another's successes and challenges in implementing sustainable policies.

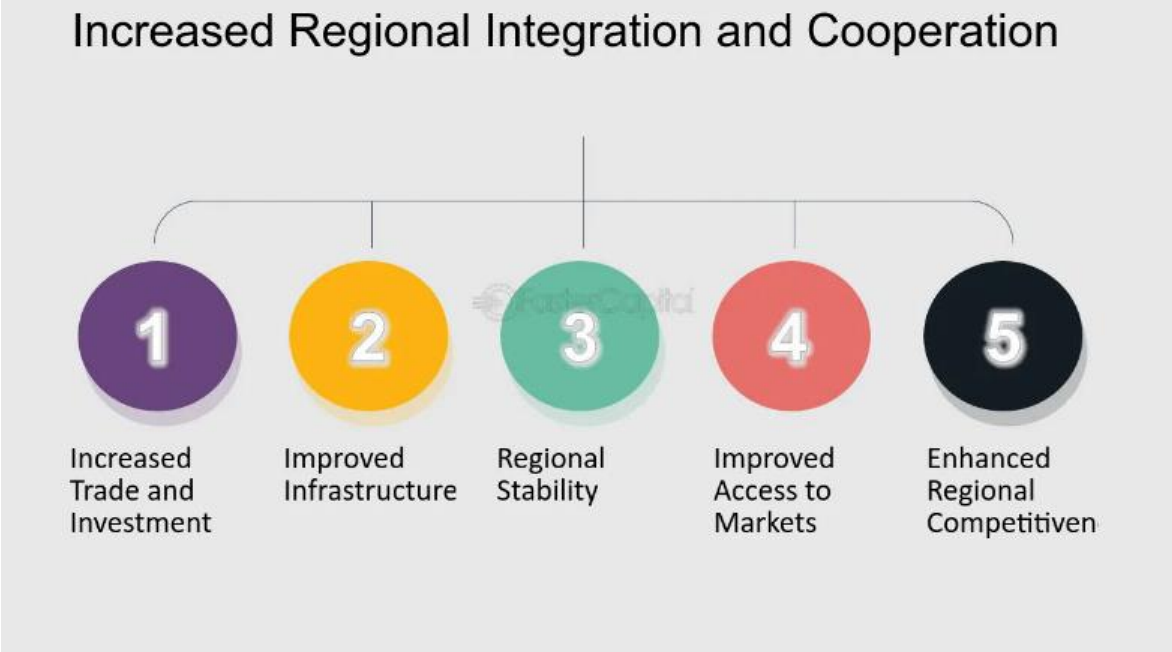

Figure 1: *Increased Regional Integration and Cooperation*

Regional integration and cooperation are fundamental to the success of the East African Community (EAC) Customs Union, which has established a single market by removing trade barriers and harmonizing trade policies. This integration is essential for promoting economic growth, creating jobs, and improving living standards across the region. The following sections explore the key benefits of enhanced regional integration and cooperation within the EAC Customs Union.

1. Increased Trade and Investment

The removal of trade barriers and the alignment of trade policies within the EAC Customs Union have facilitated cross-border business, resulting in a significant boost to trade and investment. With clearer regulations governing trade, businesses find it easier to invest in the region, further stimulating economic growth.

2. Improved Infrastructure

Regional integration has led to major infrastructure developments, such as the Standard Gauge Railway, which has enhanced connectivity and reduced transportation costs for goods across the region. This improved infrastructure not only supports smoother trade but also attracts further investment, as businesses benefit from better logistical networks.

3. Regional Stability

Collaboration among EAC member states has contributed to regional stability by fostering peace and resolving conflicts. This stable environment provides businesses with greater confidence to invest, which in turn drives economic growth and development.

4. Improved Access to Markets

The EAC Customs Union's creation of a single market has made it easier for businesses to access markets across member states. This improved market access has facilitated increased trade and investment, allowing businesses to expand beyond their home countries and tap into broader regional opportunities.

5. Enhanced Regional Competitiveness

The harmonization of trade policies has leveled the playing field, enabling businesses to compete more fairly within the region. This heightened competition encourages innovation and quality improvement, driving the region's overall competitiveness in global markets.

Increased regional integration and cooperation are crucial for the continued success of the EAC Customs Union. The benefits, including higher levels of trade and investment, improved infrastructure, greater regional stability, better market access, and enhanced competitiveness, all contribute to economic growth and improved living standards. EAC member states must maintain and strengthen their commitment to integration and cooperation to achieve long-term prosperity for the region.

However, while the potential of regional integration to advance sustainable development is significant, challenges remain. Issues such as political instability, economic disparities among member states, and the complexity of coordinating policies can hinder effective collaboration. Moreover, regional integration must navigate the tensions between national sovereignty and collective decision-making to achieve meaningful progress.

This paper aims to explore the contributions of regional integration associations to sustainable development, highlighting successful initiatives, identifying key challenges, and offering recommendations for enhancing their impact. By examining case studies from various regions, this research seeks to provide insights into the mechanisms through which regional integration can support sustainable development objectives and contribute to building a more equitable and resilient global community.

II. Methods

To investigate the contributions of regional integration associations to sustainable development, this study employs a mixed-methods approach, combining qualitative and quantitative research methodologies. The following steps outline the research methods used to gather and analyze data:

1. Qualitative Case Studies

This method involves in-depth analysis of selected regional integration associations (e.g., the European Union, African Union, ASEAN) to explore their initiatives aimed at sustainable development. The process includes:

- Selection of Case Studies: Identify associations with varying degrees of success in achieving sustainable development goals.
- Document Analysis: Review strategic plans, policy documents, and reports published by the associations to understand their objectives and measures related to sustainable development.
- Interviews with Key Stakeholders: Conduct semi-structured interviews with policymakers, experts, and representatives from member states to gather insights on the challenges and successes of regional initiatives.

2. Surveys of Member Countries

This quantitative method involves distributing surveys to assess perceptions and impacts of regional integration on sustainable development among member countries:

- Survey Design: Develop a structured questionnaire targeting various stakeholders, including government officials, NGOs, and private sector representatives.
- Data Collection: Distribute the surveys to a diverse sample of stakeholders within member countries of the regional integration associations. Ensure a mix of countries to capture different perspectives.
- Statistical Analysis: Analyze survey data using statistical software to identify trends, correlations, and significant differences in perceptions regarding the contributions of regional integration to sustainable development.

3. Comparative Analysis of Key Indicators

This method involves a comparative analysis of economic, social, and environmental indicators before and after the establishment of regional integration associations:

- Data Collection: Gather data on relevant indicators such as GDP growth, poverty rates, environmental sustainability measures, and social inclusion metrics from sources like the World Bank and regional statistical agencies.
- Timeframe Selection: Define a timeframe for analysis, focusing on periods before and after the formation of the regional integration association.

- Comparative Metrics: Use statistical methods (e.g., t-tests, regression analysis) to compare changes in key indicators, assessing the impact of regional integration on sustainable development outcomes across different member countries.

These methods collectively provide a robust framework for assessing how regional integration associations contribute to sustainable development, incorporating both qualitative insights and quantitative data.

III. Results

Regional integration associations make a significant contribution to achieving the Sustainable Development Goals (SDGs) by coordinating the efforts of member states in various sectors.

For example, in the Eurasian Economic Union (EAEU), integration helps strengthen economic ties between countries, promoting sustainable economic growth and improving the population's quality of life. According to Sergey Glazyev, Minister of Integration and Macroeconomics of the Eurasian Economic Commission, the focus on integration in areas such as sports, healthcare, and education contributes to achieving several SDGs aimed at enhancing social well-being.

In the Association of Southeast Asian Nations (ASEAN), regional cooperation also plays a key role. ASEAN Deputy Secretary-General for the Socio-Cultural Community, Ekkaphab Phanthavong, emphasizes that joint efforts allow countries to mobilize resources efficiently and attract investments into critical economic sectors, ultimately promoting sustainable development in the region.

By stimulating trade and economic growth, regional integration processes create conditions for more sustainable and inclusive development, which aligns with the SDGs. These efforts help reduce poverty, improve working conditions, and ensure equitable access to development benefits.

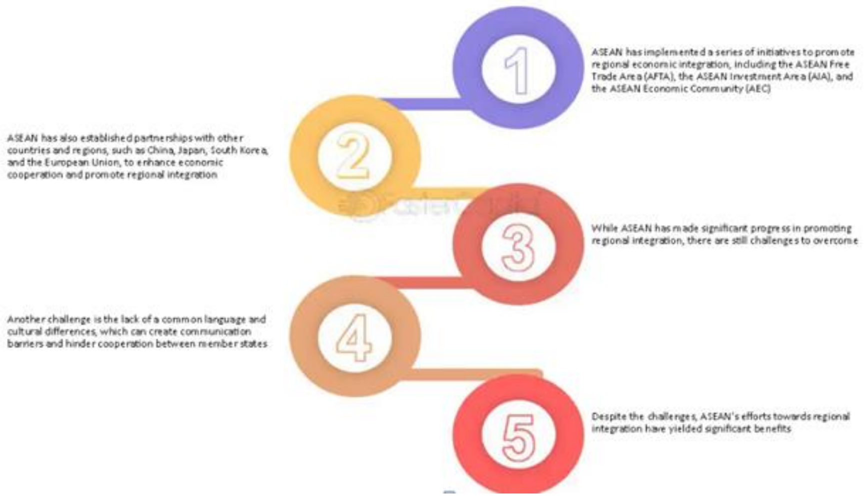

Figure 2: *The Association of Southeast Asian Nations (ASEAN)*

The Association of Southeast Asian Nations (ASEAN) is a regional intergovernmental organization comprising ten Southeast Asian countries, with the goal of fostering economic growth, social progress, and cultural development in the region. Its member countries include Brunei Darussalam, Cambodia, Indonesia, Laos, Malaysia, Myanmar, the Philippines, Singapore, Thailand, and Vietnam. The organization has played a key role in creating a more integrated regional economy, with a combined population of over 640 million, a total GDP of $2.8 trillion, and a trade volume of $2.6 trillion, making it the world's seventh-largest economy.

Key aspects of ASEAN regional integration:

1. ASEAN has introduced several initiatives to promote regional economic integration,

including the ASEAN Free Trade Area (AFTA), the ASEAN Investment Area (AIA), and the ASEAN Economic Community (AEC). These initiatives aim to reduce trade barriers, encourage investment, and develop a more competitive and integrated regional economy.

2. ASEAN has also built partnerships with other countries and regions, such as China, Japan, South Korea, and the European Union, to strengthen economic cooperation and enhance regional integration. For example, the ASEAN-China Free Trade Area (ACFTA) has significantly boosted trade between ASEAN and China, with bilateral trade reaching $587 billion in 2019.

3. Despite significant progress, ASEAN still faces challenges in promoting regional integration. One major issue is the development gap among member states, with some countries being more economically advanced than others. This disparity can slow the implementation of regional initiatives and lead to uneven economic growth.

4. Another challenge is the lack of a common language and the cultural differences across member countries, which can create communication barriers and hinder cooperation. However, ASEAN has taken steps to encourage cultural exchange and language learning to address these obstacles.

5. Despite these challenges, ASEAN's efforts towards regional integration have yielded notable benefits. The creation of AFTA, for instance, has increased trade and investment within the region, contributing to economic growth and job creation. Additionally, the "ASEAN Way," which emphasizes consensus-building and non-interference in member states' domestic affairs, has helped to maintain regional stability and prevent conflicts.

In summary, ASEAN's regional integration has been key in building a more cohesive and competitive regional economy. While challenges remain, ASEAN's initiatives have brought significant advantages to its member states and the region as a whole.

IV. Discussion

The concept of the "risk society," introduced by Ulrich Beck in the 1980s, is being reinterpreted in new ways today. Global crises, military-political conflicts, hybrid threats, and futurological alarmism are shaping the current agenda of social sciences. The fundamental socio-natural contradiction—the inability of the biosphere to meet the demands of a growing population—has been compounded by economic, social, and geopolitical crises. In the context of "ecological urgency" and widespread negative changes that threaten global destabilization, humanity is facing the necessity of finding collective solutions to a complex set of interrelated problems or, at the very least, minimizing their consequences.

The limits to growth, outlined nearly half a century ago in the reports of the Club of Rome, now seem more utopian, and the primary task has become the preservation of the integrity and sustainability of the planetary ecosystem amidst increasing anthropogenic pressure and destructive climate changes. While the paradigm of "sustainable development" remains highly debated, a growing consensus has emerged regarding its lack of alternatives. This characteristic distinguishes it from other political-economic models of the future, which continue to offer multiple variants. The political concept of sustainable development, despite numerous contradictions, has not yet exhausted its potential and continues to be recognized as one of the core doctrines of the international community.

The Sustainable Development Goals (SDGs), adopted by the UN, represent an ambitious program aimed at creating a better future by 2030. Following the Millennium Development Goals (MDGs), introduced in 2001, the number of SDGs was increased from 8 to 17, and the number of tasks rose from 21 to 169. The regional contribution to achieving these goals, including efforts by regional integration organizations (RIOs), plays a significant role. The growing influence and capabilities of RIOs are evident as they impact socio-economic development, especially in the context of the restructuring of the global economic architecture. They are becoming important actors in international relations and are expected to make global governance more systematic and effective in the future. Modern regionalization, accelerated by ongoing crises and unpredictable risks, is transforming the world into a decentralized networked space, intensifying competition among various actors, with RIOs playing a key role in shaping the global future.

Research is focused not only on the sustainability of RIOs themselves but also on their potential to stabilize the global political landscape. The events of 2022–2023 have raised skepticism about the comprehensive achievement of the SDGs within the Eurasian integration region. Disruptions in supply chains, rising prices for raw materials and commodities, including food, create significant obstacles, particularly in meeting goals related to eradicating hunger (SDG 2) and ensuring health and well-being (SDG 3). As noted by Sergey Glazyev, Minister for Integration and Macroeconomics of the Eurasian Economic Commission (EEC), global resources and technologies have the capacity to produce food for 20 billion people, twice the current global population. However, the problem lies in the fair distribution of these resources, the development of equitable international economic relations, and the regulation of prices driven by quantitative easing policies of countries that issue reserve currencies.

Ensuring the effectiveness of the transition to sustainable development requires the development of an adequate system of goals and indicators. This involves improving existing statistical measures that reflect the achievement of SDGs within the Eurasian Economic Union (EAEU), as well as creating new indicators in areas that are not currently covered. It is also essential to implement international standards and recommendations to enhance the quality and comparability of economic statistics. This is particularly relevant for the creation of the EEC's own "sustainable development dossier" for the EAEU and for preparing new reports. Additionally, coordination of statistical activities within the EAEU region, capacity building in research and professional expertise, and the adoption of advanced international standards in methodology and classification are gaining increased significance.

Human development encompasses key dimensions such as governance, health, life expectancy, education (mean and expected years of schooling), and per capita income, all of which contribute to a stable standard of living (fig.3). However, without sustainability and empowerment, human development faces challenges in promoting long-term progress. The relationship between human development and sustainable development is well-established, with studies consistently showing that improvements in human capital positively influence sustainable growth and global integration.

Figure 3: *Human Development for everyone*

Human development focuses on creating a sustainable society by enhancing health, knowledge, and well-being. It emphasizes a healthy, long life, access to knowledge, and a decent standard of living, all of which are critical for assessing progress over the long term. Research shows a positive and significant relationship between human development and sustainable development, with improvements in human capital contributing to sustainability.

For instance, Hess (2015) studied sustainable development by examining the Human Development Index (HDI) as an independent determinant, using adjusted net savings as a proxy for sustainable development. His work extended the Solow growth model and found that while initial HDI levels can present ambiguous effects on economic growth, components like life expectancy and literacy positively impact long-term economic development. HDI has been shown to have a significant positive impact on sustainable policies and outcomes.

Similarly, Boyacıoglu (2008) investigated the relationship between health indicators and sustainable development in Turkey, comparing it with other countries between 1980 and 2008. The study demonstrated that increased health expenditure in Turkey led to a decrease in the mortality rate and a rise in life expectancy, highlighting the link between health investment and human development.

Chikalipah and Makina (2020) further support the co-integration of human development and sustainable growth. They suggest that improving human capital creates a more sustainable society, consistent with the principles of social welfare theory, which focuses on the collective well-being of society as a foundation for sustainable development.

When analyzing the alignment of countries' and regional integration organizations' positions on achieving Sustainable Development Goals (SDGs), it is crucial to consider the persistent macroeconomic inequalities on a global scale. For instance, most African Union countries, as well as some members of MERCOSUR and ASEAN, fall into the category of aid recipients. In global discussions, including within the Group of 77 format, they have frequently emphasized the inadequacy of resources to achieve SDGs. Therefore, essential components of addressing these issues must include investments, financial assistance, and technology transfers from developed to developing countries ("North-South" cooperation).

For these countries, achieving not only SDGs 1 and 2, but also combating drought, reducing subsidies in the agricultural sector of developed countries, adopting a sustainable ecosystem approach to land resource management, and technology transfer (particularly pertinent for the African Union) for agriculture, infrastructure, and communications development are of critical importance. Even with SDG 9, the implementation of the Bali Strategic Plan to provide technical support to developing countries and ensure the full functioning of a "technology bank" to support the innovation potential of less developed countries remains relevant.

Regarding SDGs 16 and 17, developing countries and recipient countries stress the importance of further democratizing international institutions, ensuring these countries' access to decision-making, strengthening the regulation of financial markets and institutions for global financial stability, and reforming the international monetary system. For ASEAN, MERCOSUR, and the African Union, eliminating trade protectionist measures, de-offshoring, combating aggressive tax planning, participating in developing an open, predictable, and non-discriminatory trade and financial system, regulating financial markets for a fairer and more stable financial system, and reforming major global financial organizations such as the World Bank and IMF for balanced and democratic regional representation are crucial.

Low-income countries (LICs) still lack sufficient financial space to respond to crises and invest in sustainable development due to limited international financing opportunities on acceptable terms. Unequal access to COVID-19 vaccines and the side effects of geopolitical and economic policies of the global North have negatively impacted humanitarian, social, and food crises in poor countries of the global South.

Differences persist between developed (donor) and developing (recipient) countries in achieving SDGs, which also need to be analyzed considering the interests of the Eurasian Economic Union in this context. It is conceivable that goals and objectives should be indicative and established in a "soft" regulatory framework. Their mandatory, prescriptive nature would likely face rejection from most developing countries and integration blocs. Such an approach could potentially facilitate successful goal attainment in the future and allow countries and integration blocs to benefit from global development within the triple paradigm of SDGs that integrates environmental, economic, and social factors.

Introducing a range of new variables and indicators of key SDG parameters at the regional integration organization (RIO) level and considering the feasibility of creating corresponding supranational platforms are also noteworthy. The list of priority SDGs and indicators should be reviewed based on the characteristics of RIOs (geographical, demographic, socio-economic, etc.). For example, indicators could include the well-being of the average citizen or the overall environmental impact of population activities.

At the supranational level, establishing an information system on environmental and social conditions, signs of growing inequality, failures in responsible consumption and production models—all warning signals indicating societal and environmental strain—should be considered. Information should flow promptly not only from national governments but also from representatives of NGOs and civil society agents.

A crucial aspect of this work should be the creation of regulatory acts harmonizing various areas of legislation, primarily economic, environmental, anti-offshore, anti-monopoly, and social laws. Achieving SDGs at regional levels should contribute to the political, economic, and social consolidation of the global space, significantly enhancing the international relevance of RIOs and their global institutionalization in a post-conflict world, including on democratic principles, integrating regional civil communities in line with SDG 16 (Peace, justice, and effective institutions).
