Currently, the discourse accompanying the movement towards sustainable development in integration blocs plays a critical role in strengthening their resilience, particularly vital during acute phases of crises and conflicts. Ultimately, the journey towards SDGs can organize political processes, organizational structures, and ideological solidarity at a supranational integration level. Efforts must unite to reduce risk, transform the modern "risk environment" into a space for cooperation to eliminate major threats to civilization's further development.

Regional integration has recently gained prominence, especially following the Belt and Road Initiative (BRI), playing a crucial role in connecting over 65 countries through the lens of regionalism and development theory. The objective is to foster progress across social, economic, and environmental dimensions of sustainable development. The growing interconnection of national economies through BRI exemplifies how regional integration can function as a catalyst in several ways, such as advancing trade, digital transformation, expanding markets, fostering regional cooperation, and promoting sustainable socio-economic growth. According to Yu and Chang, the BRI, grounded in regional integration and development theory, aims to enhance global collaboration and connectivity, facilitating sustainable growth and reinforcing regional ties. Such initiatives can improve human development and healthcare, creating employment opportunities and reducing the burden of old-age dependency by enabling financial savings for retirement benefits.

Obere and Muthoga investigated the impact of regional integration on economic development using the generalized method of moments (GMM) and found that regional integration significantly stimulates economic growth, highlighting the relationship between regionalization and a sustainable economy. Brautigam and Tang emphasized that China addressed sustainable economic development by offering the BRI as a proposition to achieve shared goals in human development, healthcare, and economic growth through trade, connectivity, investment, and infrastructure. Furthermore, Wang and Selina suggested that the BRI may act as a moderating force in the global application of development theory, with bilateral cooperation potentially mitigating political instability and boosting local development through regional progress.

Based on these findings, the proposed hypothesis (H4) is that there is a significant moderating effect of regional integration on the relationship between sustainable development and its determinants.

Abstract

The transition to a green economy is pivotal for achieving sustainable development in the face of escalating environmental challenges. This paper explores the transformation of traditional business models to align with green economy principles, emphasizing the integration of sustainability into core operations. By analyzing various case studies, we demonstrate how businesses can adopt innovative practices that reduce their ecological footprint while enhancing economic performance. The research highlights key strategies, such as circular economy approaches, renewable energy adoption, and sustainable supply chain management, which not only mitigate environmental impacts but also drive competitive advantage. Furthermore, we discuss the role of policymakers in fostering an environment conducive to green investments and the importance of stakeholder engagement in this transformative process. Ultimately, this paper aims to provide insights for businesses looking to navigate the complexities of sustainable development while contributing to a resilient and equitable economy.

Keywords: sustainable supply chain, environmental impact, innovation, competitive advantage, stakeholder engagement, policy framework, eco-friendly practices

I. Introduction

As global environmental challenges intensify, the need for a transition to a green economy has never been more urgent. A green economy is defined as one that results in improved human well-being and social equity while significantly reducing environmental risks and ecological scarcities. This paradigm shift is essential for addressing issues such as climate change, resource depletion, and biodiversity loss, which pose significant threats to sustainable development.

Traditional business models often prioritize short-term profits over long-term sustainability, leading to practices that are harmful to the environment. However, an increasing number of businesses are recognizing the importance of integrating sustainability into their operations. This transformation not only addresses ecological concerns but also opens up new avenues for innovation and competitive advantage. By adopting green practices, companies can enhance their brand reputation, attract environmentally conscious consumers, and achieve operational efficiencies.

This paper explores how businesses can successfully transition to more sustainable models by examining key strategies, including the circular economy, renewable energy integration, and sustainable supply chain management. It also emphasizes the critical role of policymakers in creating an enabling environment for green investments and fostering collaboration among stakeholders. Through this comprehensive analysis, we aim to provide insights and practical recommendations for businesses seeking to thrive in a green economy while contributing to sustainable development goals. This study delves into the concept of the green economy and its impact on economic development and operational practices. It is based on the premise that traditional linear business models have become unsustainable due to their detrimental effects on the environment, the depletion of natural resources, and the decline in living standards. In light of these challenges, the green economy, which is intricately linked to the principles of the circular economy and bioeconomy, emerges as a crucial framework for fostering sustainable development. The primary objective of this exploration is to establish a balance among the enduring social, environmental, and economic goals of humanity.

Figure 1: *Inclusive Green Economy*

The Inclusive Green Economy (IGE) model, illustrated in Fig. 1, distinguishes itself from traditional economic models by integrating three core components: environmental, social, and economic factors. Emerging from the green economy concept, IGE emphasizes a low-carbon, efficient, and clean production process, while also highlighting aspects of consumption and outcomes centered around sharing, circular practices, collaboration, solidarity, resilience, opportunity, and interdependence. The IGE framework posits that there are multiple pathways to achieving environmental sustainability. Transitioning to an inclusive green economy necessitates the promotion and support of sustainable lifestyles, the enhancement of sustainable consumption and production (SCP), and the encouragement of eco-innovation and resource efficiency. This green economic approach, which includes Corporate Social Responsibility (CSR), offers numerous advantages, including economic, health, safety, social, and environmental benefits. Integrating a green economy within an existing organization presents challenges, but one effective strategy is to manage the business model in a way that incorporates green management principles, ultimately enhancing Corporate Social Responsibility.

By examining the core components of the green economy, this paper presents an innovative development framework that encourages the integration of green, circular, and bioeconomic principles. Such integration is essential for promoting future economic and social progress while ensuring environmental sustainability. Through this analysis, we aim to highlight the potential pathways for businesses and policymakers to transition towards more sustainable practices, ultimately contributing to a resilient and equitable economy. Over the last decade, a frequent claim has been that traditional economic models need to be reformed to address climate change, biodiversity losses, water scarcity, and other pressing challenges while simultaneously tackling key social and economic issues. The global financial crisis of 2008–2009 intensified this debate, leading to the emergence of the vision of a 'green economy'. In 2015, countries worldwide adopted the 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs).

These goals recognize that ending global poverty must go hand-in-hand with strategies for economic growth while addressing various social needs, including education, health, social protection, and job creation, all while tackling environmental pollution and climate change.

The SDGs establish a real link between ecological and economic systems and reinforce the necessity for a transition to a green economy, which implies a fundamental transformation toward more sustainable modes of production and consumption. This article focuses on a particularly critical aspect of such a transition: the development of sustainable technological change. This change refers to production and consumption patterns that result in significantly reduced negative impacts on the natural environment, including global climate change.

Specifically, the article discusses several key challenges in supporting sustainable technological change and overcoming the barriers to it. These challenges aim to communicate essential lessons from academic research to policymakers, professionals, and the general public. Addressing climate and environmental challenges requires not only natural scientific knowledge and engineering expertise regarding various technical solutions (such as carbon-free energy technologies) but also recognition that pursuing sustainable technological change is a societal, organizational, political, and economic endeavor involving several non-technical challenges.

Our planet is currently confronted with significant economic, social, and environmental challenges. In response to these issues, the Sustainable Development Goals (SDGs) outline global priorities and aspirations for 2030, presenting an unparalleled opportunity to eradicate extreme poverty and guide the world toward a sustainable future.

Governments around the world have already committed to these goals, and it is now imperative for businesses to take action. The SDG Compass provides insight into how the SDGs impact your business, equipping you with the tools and knowledge needed to embed sustainability into the core of your business strategy.

The guide outlines five steps that companies can take to enhance their contributions to the SDGs. Organizations can use these steps to either set new goals or align their existing strategies, depending on their current stage in integrating sustainability into their core business practices.

Figure 2: *The SDG Compass*

For instance, the transitions literature identifies many sectors—such as energy generation and water supply—as socio-technical systems and innovation systems. These systems consist of networks of actors (individuals, private firms, research institutes, government authorities, etc.), the knowledge these actors possess, and the relevant institutions (legal rules, codes of conduct, etc.). The development of new carbon-free technologies often necessitates the establishment of new value chains involving actors that may not have previously interacted. This process can be lengthy and transformative, resulting in legal amendments, changes in consumer behavior, distributional effects, infrastructure development, and the emergence of novel business models.

II. Methods

Literature Review

- Description: A systematic literature review will be conducted to synthesize existing research on green economy principles, circular economy, bioeconomy, and sustainable development. This will include academic journals, policy papers, and reports from international organizations (e.g., UNEP, EU, World Bank).
- Process:
  - Identify key themes, frameworks, and case studies relevant to the green economy.
  - Analyze previous findings to understand the evolution of the green economy concept and its implications for business models.
  - Summarize the benefits and challenges associated with implementing green economy practices in various sectors.

Case Study Analysis

- Description: This method will involve in-depth case studies of specific countries or regions that have successfully transitioned to a green economy, as well as those still in the early stages of this transition.
- Process:
  - Select case studies from both developed (e.g., EU countries) and developing regions (e.g., Western Balkans) to provide a comparative analysis.
  - Examine policies, initiatives, and business practices that illustrate the transformation from traditional models to green economy practices.
  - Evaluate the outcomes, focusing on economic, environmental, and social impacts, and derive best practices and lessons learned from each case.

Stakeholder Interviews

- Description: Semi-structured interviews will be conducted with stakeholders involved in the implementation of green economy initiatives, including policymakers, business leaders, environmental NGOs, and academic researchers.
- Process:
  - Develop an interview guide with open-ended questions aimed at understanding stakeholders' perspectives on the challenges, opportunities, and effectiveness of green economy initiatives.
  - Conduct interviews with a diverse range of stakeholders to capture various viewpoints and insights.
  - Analyze the interview data using thematic analysis to identify common trends, barriers, and recommendations for enhancing the transition to a green economy.

III. Results

The term "green economy" is defined by the United Nations Environment Programme (UNEP) as an economy that enhances social well-being and reduces inequalities while significantly decreasing environmental risks and ecological scarcities (UNEP 2011) (fig.3). The fundamental components of green economies include the circular economy, bioeconomy, clean technologies, waste management hierarchy, industrial ecology, and strategies focused on environmental conservation and restoration. Numerous international organizations, such as the UN, IMF, World Bank, and World Trade Organization, support the effective implementation of green economy practices.

The European Union's "European Strategy for the Bioeconomy," adopted in 2012, defines the bioeconomy as a process involving the use of renewable biological resources to produce food, biomaterial-based products, and bioenergy. This strategy highlights the potential for utilizing renewable biological resources, emphasizing the need for sustainable manufacturing and bioenergy generation. However, transitioning to these new production methods requires the adoption of innovative and often significantly different technologies. Thus, the successful implementation of these emerging development paradigms calls for innovative solutions across various sectors, including product development, materials, and technological and organizational processes.

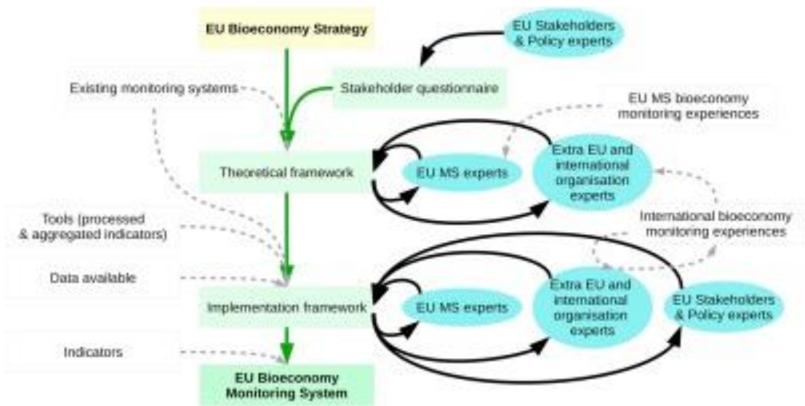

Figure 3: *Development of a bioeconomy monitoring framework for the European Union*

Technological and metallurgical innovations play a crucial role in this transition, facilitating the creation of products and services and adopting processes that are economically viable while minimizing environmental degradation. The metallurgy sector, which is fundamental to civilization's advancement, must embrace the principles of the green economy. The sector's significant growth has presented considerable energy and environmental challenges. Transitioning from traditional to green metallurgical processes offers substantial benefits, as conventional practices heavily depend on fossil fuels, resulting in considerable CO_2 emissions. There is an urgent need for innovative strategies to replace fossil fuels with renewable energy sources while also reducing energy consumption and CO_2 emissions.

As a result, topics such as the substitution of renewable energy for fossil fuels, the utilization of metallurgical slag as a resource, low-carbon smelting technologies in the steel industry, and the mechanisms and control processes for producing non-quenched and tempered high-strength steel for automotive applications have gained significant attention for their potential in energy recovery and technological advancement within the metallurgy sector.

The European Union employs the ecological innovation index to measure the progress of ecological innovations among its member countries. This index comprises sixteen indicators organized into five thematic categories: resources essential for developing ecological innovations, activities conducted during the ecological innovation process, outcomes of ecological innovations, achieved resource use efficiency, and socio-economic impacts.

IV. Discussion

One of the fundamental principles of the green economy is the bioeconomy, which emphasizes the utilization of renewable biological resources for producing materials, chemicals, and energy . This methodology converts sustainable biological resources into value-added products. Perspectives on the bioeconomy vary depending on its focus, which includes resources such as biomaterials and energy derived from agriculture, oceans, and forests, as well as biotechnology with an emphasis on the commercialization of biotech innovations and ecological processes coupled with territorial adaptation. EU documents highlight the importance of integrating the bioeconomy with the circular economy, focusing on concepts such as value chain oversight, sustainability, biorefining, efficient resource use, and cascading biomass utilization. They underscore the crucial role of research, innovation, and societal shifts towards sustainability.

The concept of the circular economy promotes a business model that facilitates the cyclical movement of materials and energy. The primary objective of this initiative is to enhance the durability of materials and energy through inventive design strategies and recycling practices. This approach aims to reduce waste, promote the adoption of renewable energy sources, and ensure that pricing accurately reflects actual costs. Implementing the principles of the circular economy requires a holistic approach across macro, meso, and micro levels. At the macro level, it necessitates reconfiguring the entire industrial framework of an economy. The meso level focuses on regional economies, particularly eco-industrial parks, whereas the micro level deals with individual businesses, consumers, and products. Essentially, the circular economy aims to create a closed loop that encompasses the procurement of raw materials, their conversion into products, and the recycling of resources for use in subsequent production cycles.

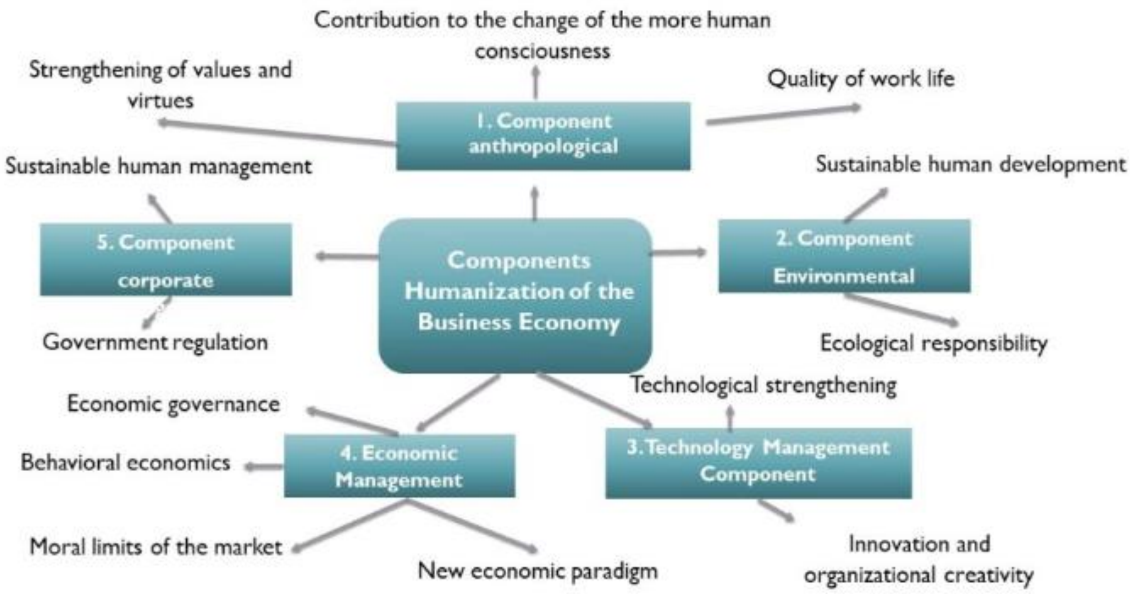

Figure 4: *Hybrid model for the humanization of the business economy and corporate social responsibility*

The model developed, drawing on both classical and modern economic theories, aims to identify and understand potential gaps in knowledge among companies regarding various critical topics. These topics include the strengthening of values and virtues, shifts in human consciousness, sustainable development, technological advancement, innovation and creativity, quality of work life, ecological responsibility, economic governance, behavioral economics, moral limits of the market, and the emergence of a new economic paradigm emphasizing more humane management.

The underlying concern is that ignorance in these areas can hinder companies from implementing humanization policies within the business economy. The strength of this hybrid model lies in its integration of components and principles derived from the theories and authors studied. By addressing these gaps, the model aims to foster more sustainable businesses and environmentally conscious consumers.

Furthermore, the application of this model is anticipated to enhance companies' competitiveness, productivity, research capabilities, innovation, and technology, all within a framework of social responsibility. Ultimately, the purpose of this model is to engage stakeholders—including business leaders, employees, and consumers—in adopting best practices for humanizing the business economy, thereby promoting sustainability and long-term viability.

The mission of the circular economy is to maximize the conservation and enhancement of natural capital by keeping materials and components in use for as long as possible and extending product lifespan.. This approach aims not only to boost business efficiency but also to mitigate and eliminate external economic impacts harmful to human health, natural environments, and ecological systems.

The analysis of the principal characteristics of the green, bioeconomy, and circular economy reveals that, although distinct, these concepts complement each other. For long-term sustainable development, it is essential to apply all three concepts simultaneously. Systemically, the bioeconomy and circular economy act as subsystems within the green economy framework. The circular economy utilizes both renewable and non-renewable resources, while the circular bioeconomy exclusively employs renewable resources to transform waste into value-added products.

Implementing the green economy concept is vital not only for meeting economic objectives but also for addressing environmental and social goals. This approach can lead to numerous positive outcomes, including:

- Enhanced well-being for individuals
- Reduction of poverty
- Achievement of social equality
- Minimization and elimination of environmental damage
- Decrease in carbon emissions
- Complete elimination of pollution
- Primarily utilizing renewable energy sources
- Creation of new green employment opportunities
- Mitigation of biodiversity loss
- Proper waste management.

Thanks to their advanced economic and technological progress and available resources, developed nations have been the pioneers in adopting green economy principles. In contrast, countries in the Western Balkans, including our own, are just beginning to undertake this endeavor, embracing it at a significantly slower rate.

The primary challenges hindering a smooth transition to these new "green" development models include a low level of economic development, an inadequate economic structure, and a scarcity of necessary resources. The adoption of the "Action Plan for the Common Regional Market of the Six Western Balkan Countries for the Period 2021-2024" at the Berlin Process summit in Sofia, along with the document "Common Regional Market - A Catalyst for Deeper Regional Integration, Economic Integration, and a Step Towards the EU Single Market," addresses the development challenges of underdeveloped countries that impede the progress of developed nations. These documents underscore the necessity for Western Balkan countries to enhance their economic competitiveness and expedite their integration into the single European market.

Establishing a digital, investment, and industrial innovation zone in the region, aligned with EU regulations, is highlighted as a significant factor in achieving this objective more swiftly. The "Green Agenda for the Western Balkans for the Period 2021-2030" outlines the commencement of the transition towards "green" economic practices within the Western Balkan countries. This agenda identifies the primary pillars for these countries' long-term green economic transition as follows:

1. Climate, energy, and mobility
2. Circular economy
3. Reduction of environmental pollution
4. Sustainable agriculture and food production
5. Biodiversity conservation

MORPHODYNAMICS OF THE BLACK SEA COASTAL ZONE OF ADJARA AND MODERN APPROACHES

İrma Makalatia, Kakhaber Bilashvili, Davit Kereselidze

•

Ivane Javakhishvili Tbilisi State University, GEORGIA
Irma.makalatia@ens.tsu.edu.ge

Abstract

The coastline of Adjara, especially the Cape of Batumi, is an active area, which is caused by the underwater canyon of Batumi. It was influenced by the construction of Batumi port in 1878. To protect the port from the impact of storm waves and flooding, a 170-meter-deep dam was built, which eventually caused the Batumi Accumulation Basin to rise sharply, causing it to approach the Batumi Underwater Canyon. The average width of the beach today is 70-80 meters and the threat is growing, as already happened on January 14, 1999, when a beach of about 200 meters long with a total area of 11000 m² washed ashore and sank into the Batumi Canyon. The incident reportedly occurred during the night, triggered by a small earthquake in the city of Trabzon. the construction of dams in the river Chorokhi basin, since the 1990s, had an extremely negative impact on the southern section of the Black Sea coast. (These references are taken from examples of coastal hazard along the Georgian black sea coast: "Examples of coastal hazard along the Georgian black sea coast" Gelovani, I., Lominadze, G., Kavlashvili, G., Russo, G. NATO Science for peace and Security Series C: Environmrntal security, 2021, pp.317-326.)

The innovative project of the company "Ambassador Batumi Island" involves the construction of two artificial peninsulas and an island at the entrance of Batumi, in the settlements of Barchan and Tamar. An area of 144.3223 m² has been allocated for the project, of which 108.50632 m² will be used for various purposes, of which 84 m² will be artificially created area, while the rest will be devoted to protective moles and artificial island aquarium.

The project was preceded by two years of preparatory work, a detailed study of the Black Sea coast. More than 30 local and international studies have been conducted. Three alternative sites were selected for the construction. Eventually, after laboratory findings and expert advice, the Cape of Batumi was chosen for artificial development. More than five hectares of land has already been developed, and work is underway to improve the waterfront. A bridge was constructed to carry heavy equipment, and the necessary infrastructure was put in place. It is worth noting that the seven-ball storms in Batumi in 2023 and 2024 had no impact on the ongoing construction in the Gulf, which confirms that the geographical location for the project was selected with caution by qualified specialists. Planning takes into account an eight-point seismicity and the global warming-related tendency for water to rise.

The EIA (Environmental Impact Assessment) concludes that the environmental impact of a construction site can be reversed in 5 to 10 years. The island will have a well-developed blue-green infrastructure that will create a new landscape and integrated ecosystem for the population. The territory of the island should be created an outstanding architectural example of world importance, which will make the city of Batumi more distinctive and attractive. The work carried out along the Black Sea coast may lay the foundation for new modern approaches that are important and necessary for us as a maritime country.

Keywords: Black Sea, future project, artificial island

Introduction

The coastline of Adjara, especially the Cape of Batumi, is an active area, which is caused by the underwater canyon of Batumi. It was influenced by the construction of Batumi port in 1878. To protect the port from the impact of storm waves and flooding, a 170-meter-deep dam was built, which eventually caused the Batumi Accumulation Basin to rise sharply, causing it to approach the Batumi Underwater Canyon.

Figure 1: *Completed "Ambassador Batumi Island"*

The average width of the beach today is 70-80 meters and the threat is growing, as already happened on January 14, 1999, when a beach of about 200 meters long with a total area of 11000 m² washed ashore and sank into the Batumi Canyon. The incident reportedly occurred during the night, triggered by a small earthquake in the city of Trabzon. the construction of dams in the river Chorokhi basin, since the 1990s, had an extremely negative impact on the southern section of the Black Sea coast. (These references are taken from examples of coastal hazard along the Georgian black sea coast) "Examples of coastal hazard along the Georgian black sea coast" Gelovani, I., lominadze, G., Kavlashvili, G., Russo, G. NATO Science for peace and Security Series C :Environmrntal security, 2021, pp.317-326

Method

In order to better solve the problem, joint work of the state and private investors is necessary. As an example of modern approaches, I have cited the project of "Ambassador Batumi Island" LLC, which envisages the construction of two artificial peninsulas and an island. [Fig.1] An area of 1 443 223 m² has been allocated for the project, of which 108.50632 m² will be used for various purposes, of which 84 m² will be artificially created area, and the rest will be reserved for protective moles and artificial island aquatoria.

The settlements of "Bartskhani" and "Tamar" at the entrance of Batumi have been selected for construction, the infrastructure is currently in place, appropriate equipment has been purchased, a connecting bridge has been built, and an area of more than 5 hectares of land in the water has been arranged.

The big storms of Batumi in November-January 2023-24 did not affect the area under construction, which proves that the geographical location of the island was chosen correctly. The project was preceded by two years of more than 40 local and international studies. 8-point seismicity and global warming-related rising water trends are considered. In the framework of the Ambassador Batumi Island project in Ankara, Republic of Turkey, testing and additional studies were conducted in the hydraulic laboratory, the purpose of which is the engineering stability of the two peninsulas and the island structure. The intersection of the two waves and the speed of the wave were checked. The terrain, geological structure, landscape, hydrology, wave regime, morphodynamics of the construction area of the artificial island were studied by joint researches of local and foreign scientists

As a result, it was concluded that the implementation of the artificial island project will not have a negative impact on the sustainability of the sea coast. Soil settlement estimation was done using Settle3 software. Various preventive measures will be implemented during the construction period. The project envisages the arrangement of pumping equipment, which ensures the pumping of water from the internal aquarium to the external aquarium. Monitoring of water pollution and quality in the relevant catchment basin will be carried out systematically. Observation of the biological environment of the sea will be conducted twice a year and additional mitigation measures will be implemented if necessary. According to the results of the research of water and bottom sediments of the marine aquaria, it was established that at a distance of 60-70 m, there is a high level of historical pollution of the sediments of the bottom slope of the underwater slope with oil and oil products. In the coastline, the river Bartskhana and river Kubistskal used to discharge water contaminated with petroleum products into the sea. The construction of the artificial peninsula and island will permanently cover the historically polluted seabed. As a result, the risk of contamination is eliminated. In case of contamination of sea water and bottom sediments, mitigation measures will be implemented. In order to study the background condition of the bottom sediments quality, field work and laboratory research of the taken samples will be conducted twice a year. The island will have a well-developed blue-green infrastructure that will create a new landscape and an integrated ecosystem for the population. Stones, concrete inert material required for the purposes of the project will be brought in ready form from licensed quarries. This will certainly reduce the risks of environmental impact, such as the spread of dust in the ambient air, the spread of noise and the impact on the water environment. (Fig. 2 and 3.)

"Ambassador Batumi Island", at the stage of development of the technical-economic study, design and development of the master plan of the artificial island, cooperates with the largest international corporations such as Colliers (Great Britain), Arup GROUP (Great Britain), Yuksel Proje (Turkey) SHOP Architects (USA) etc.

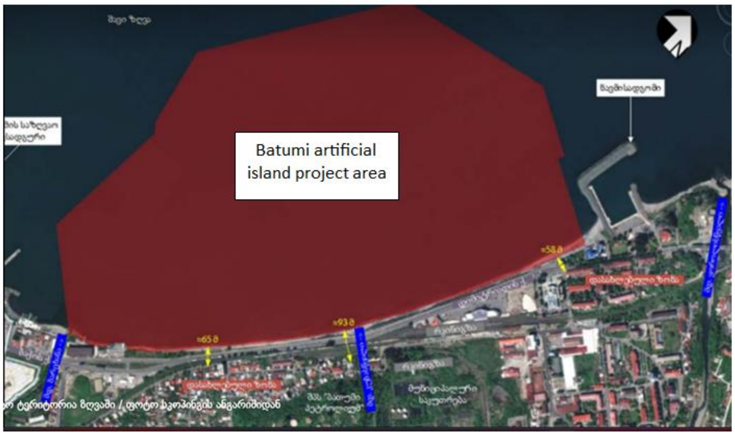

Figure 2: Artificial island project area

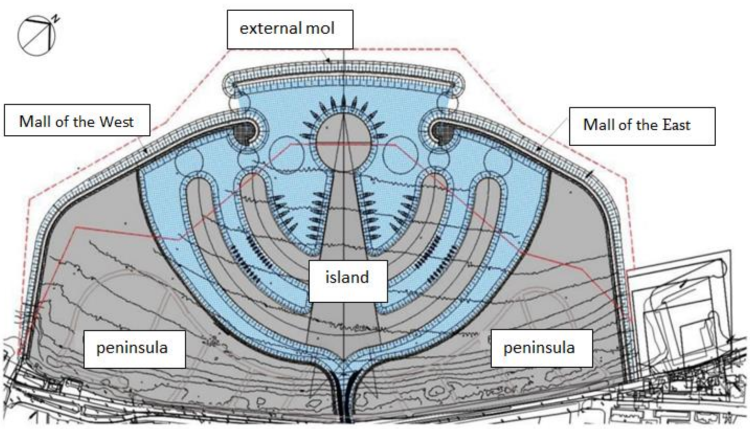

Figure 3: *Gen plan*

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

Conclusion

The Ambassador Batumi Island is an important project for the region. In the course of the planned activities, mitigation measures will be taken to reduce the negative impact on the environment. Geological engineering studies indicate that geological processes are not expected to have a high risk of impacting newly constructed infrastructure. It is also worth noting that the company's management gives students the opportunity to participate in this project and receive qualified education with foreign specialists. The territory of the island should be created an outstanding architectural example of world importance, which will make the city of Batumi more distinctive and attractive. The work carried out along the Black Sea coast may lay the foundation for new modern approaches that are important and necessary for us as a maritime country.

Abstract

This article examines the pivotal role that legal frameworks play in achieving the United Nations' Sustainable Development Goals (SDGs). The SDGs, established in 2015 as part of the 2030 Agenda for Sustainable Development, represent a global commitment to addressing social, economic, and environmental challenges.

The implementation of these goals requires a coordinated effort across national, regional, and international levels, where legal mechanisms are key enablers of effective action. The text explores how laws, regulations, and policies can help institutionalize the SDGs by embedding sustainable development principles into legal systems. This includes integrating international agreements into national legislation, ensuring accountability through judicial and non-judicial bodies, and creating enforcement mechanisms to monitor compliance. Specific examples of legislation that support SDG implementation include environmental protection laws (SDG 13: Climate Action), gender equality policies (SDG 5: Gender Equality), and economic regulation aimed at reducing poverty and inequality (SDG 1: No Poverty, SDG 10: Reduced Inequalities). Moreover, the article discusses the challenges that arise in the harmonization of legal systems across different jurisdictions, particularly in developing countries with limited legal infrastructure. It highlights the need for legal capacity building, effective governance structures, and international cooperation to strengthen the legal enforcement of SDG-related commitments.

In conclusion, legal mechanisms are essential for translating the SDGs from global aspirations into tangible actions. They provide the structure for implementing sustainable policies, ensuring accountability, and fostering an environment where sustainable development can thrive. By supporting a rule-based approach, legal systems play a crucial role in advancing the global sustainability agenda.

Keywords: sustainable development goals (SDGs), legal mechanisms, international law, national legislation, environmental protection, accountability, governance, legal frameworks

I. Introduction

The UN Sustainable Development Goals (SDGs) (Fig.1) were established by the United Nations as a "universal call to action" to eliminate poverty, safeguard the environment, and guarantee that by 2030, everyone can experience peace and prosperity. These goals have gained significant traction among managers in both public and private sectors. Many organizations have begun including their contributions to specific SDGs in formal reports to stakeholders, such as annual reports. Although not originally intended for this purpose, the SDGs are increasingly being used as a tool for accountability. However, their use in this capacity comes with challenges. One issue is that organizations may—either deliberately or unintentionally—report only on activities that align with a limited set of goals, which fails to provide the comprehensive information necessary for the SDGs to function effectively as an accountability mechanism.

Figure 1: *Sustainable Development Goals (SDGs)*

Despite their widespread appeal, little is known about the broader implications (both positive and negative, intended and unintended) of incorporating SDGs into organizational management practices. This leads to the central question of the research: "What is the potential role of the SDGs as an accountability mechanism?" While some studies have examined the drivers and outcomes of SDG reporting, they have predominantly been quantitative. To better understand the SDGs' potential as an accountability tool, qualitative research is essential, as it allows for deeper exploration of new phenomena without imposing pre-existing frameworks. This study focuses on the infrastructure sector, where many organizations have adopted and reported on the SDGs. This sector is especially relevant due to its critical role in providing essential services, such as electricity, heating, transportation, and water, which are foundational to society. As a result, infrastructure agencies operate in a highly regulated environment. This raises an important question: How can accountability to societal needs be effectively ensured for organizations responsible for vital infrastructure? Changing the mindset of organizations that manage key technological systems, such as power grids, water supply systems, or rail networks, is crucial for broader accountability. However, these organizations face challenges in implementing societal needs, as they are constrained by legal requirements and shareholder expectations. This article explores how infrastructure organizations are using the SDGs as an accountability mechanism. It first provides an overview of the SDGs and the concept of accountability, followed by a case study methodology. The research is based on interviews with employees from three infrastructure organizations. Through this case study, the authors analyze the key tensions that arise when using the SDGs for accountability. In conclusion, the article argues that while the SDGs offer a useful tool for making organizations more accountable to societal needs, significant changes in the design of accountability mechanisms are required to achieve meaningful accountability.

II. Methods

To investigate how the SDGs function as an accountability mechanism in the infrastructure sector, this study employs a qualitative case study approach. This method allows for in-depth exploration and understanding of complex phenomena in their real-life context. The research focuses on three organizations within the infrastructure sector, chosen for their critical role in providing essential services (electricity, water, and transportation) and their adoption of SDG reporting.

The study uses semi-structured interviews as the primary data collection method, targeting key employees involved in SDG implementation and reporting. These interviews provide insights into how these organizations integrate the SDGs into their management practices, how they report on their contributions, and the challenges they face in using the SDGs as an accountability tool. The semi-structured format allows flexibility in exploring new themes that arise during the interviews.

In addition to interviews, document analysis is conducted on relevant organizational reports, including annual reports and sustainability documents, to understand how these organizations publicly communicate their alignment with the SDGs. This analysis helps verify the consistency between the organizations' internal practices and their external communication.

The data collected is then analyzed using thematic analysis, which involves coding the interview transcripts and documents to identify recurring themes and patterns related to SDG reporting and accountability. This method facilitates the identification of key tensions and challenges, as well as the broader implications of using the SDGs as an accountability mechanism.

The results of the case study are presented in a narrative format, discussing the specific findings from the infrastructure sector while drawing broader conclusions about the use of SDGs in organizational accountability.

III. Results

On 25 September 2015, the UN General Assembly adopted the 2030 Agenda for Sustainable Development, an ambitious action plan aimed at improving the lives of individuals, protecting the planet, and fostering prosperity. This agenda, which also strives to promote universal peace and freedom, was introduced as a means to achieve targets that the Millennium Development Goals had failed to meet. The agenda includes 17 Sustainable Development Goals (SDGs) and 169 specific targets, with a strong focus on realizing human rights for all, promoting gender equality, and empowering women and girls.

The 2030 Agenda is more ambitious than its predecessor, extending its objectives beyond poverty reduction and environmental protection. It emphasizes five key areas of action, often referred to as the 5Ps: people, planet, prosperity, peace, and partnership. These areas work together across the three dimensions of sustainable development: economic, social, and environmental. The SDGs are seen as a potential new social contract for the era of globalization, offering a framework for security and freedom worldwide.

Figure 2: *The 5Ps of Strategy*

Although the SDGs are not legally binding, the countries that have adopted them are expected to establish national or transnational frameworks to support their implementation. At the European level, the agenda aligns with existing sustainable development initiatives. The European Union was already well-positioned in terms of sustainability and played a key role in advocating for SDG 16, which focuses on promoting peaceful, inclusive societies. The agenda encourages a holistic approach, where policies at international, EU, and member state levels should address the interconnected areas of the 5Ps, avoiding compartmentalization and promoting integration across different policy areas to achieve progress in all SDGs simultaneously. The responsibility to understand and implement the SDGs is universal, as all individuals and entities are regarded as key actors in this global effort. Public authorities and civil society are called upon to be both active participants in achieving the goals and beneficiaries of the progress made across the 17 SDGs. However, the 2019 Progress Report by the UN Economic and Social Council highlights that progress has been slow, with the most vulnerable populations and countries continuing to face the greatest challenges. The report emphasizes that the global response has not been ambitious enough.

To address the slow progress, there is a growing emphasis on collaborative efforts in research and education, particularly in the field of law. Universities, through legal research and teaching, play a crucial role in advancing the SDGs. The academic and scientific communities have recognized the importance of contributing to these goals. This paper aims to explore how civil law and procedural law have created mechanisms to protect rights, reduce inequalities, and promote legal sustainability. The study will also identify existing gaps and challenges in ensuring that legal frameworks support the achievement of the SDGs.

IV. Discussion

The goal of eradicating poverty, outlined in SDG 1, must be approached at both the international and national levels. This involves developing policies focused on poverty eradication and ensuring that states take concrete legislative actions. Poverty has numerous consequences that affect various aspects of life, which is why legal frameworks must address the tools available to mitigate its effects. These frameworks also support a sustainable approach by aligning with SDG 10, which aims to reduce inequality within and among countries. Poverty serves as a condition of vulnerability that perpetuates inequality, and thus, legal systems' interventions serve to address both issues simultaneously.

The vulnerability associated with poverty often leads to difficulties in asserting the rights and interests of those affected, particularly in instances of rights violations. The EU has been actively implementing actions and strategies to combat poverty and social exclusion. In November 2017, the European Parliament, the Council, and the Commission proclaimed the European Pillar of Social Rights, which articulates 20 principles designed to support effective and equitable labor markets and welfare systems. These principles emphasize equal opportunities, access to employment, fair working conditions, and comprehensive social protection and inclusion.

Among these principles, Principle 11 specifically addresses children's right to protection from poverty and outlines measures aimed at enhancing equal opportunities for children from disadvantaged backgrounds. The European Commission has also put forth an Action Plan for the Pillar, detailing specific actions required for its implementation. This Action Plan aims to revitalize efforts to tackle poverty and social exclusion within the EU, with a target of reducing the number of people at risk of poverty or social exclusion by 15 million by 2030, or at least by 5 million.

Furthermore, the EU Strategy on the Rights of the Child emphasizes that "children will have access to quality education and healthcare, and families will have sufficient resources to meet their children's needs." The Council Recommendation establishing a European Child Guarantee underscores the EU's commitment, alongside its Member States, to lead in implementing the UN 2030 Agenda and the Sustainable Development Goals, including those focused on eradicating poverty. The aim of this Recommendation is to prevent and combat social exclusion by ensuring access for children in need to essential services. This includes integrating a gender perspective to address the different circumstances of girls and boys, combating child poverty, and promoting equal opportunities.

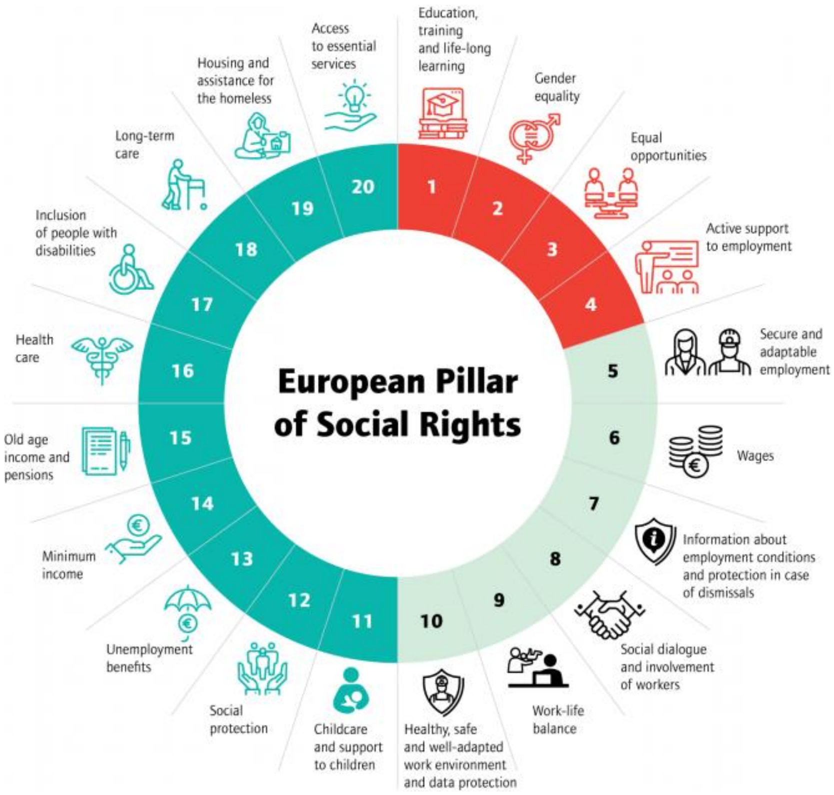

Figure 3: *The 20 principles of the European Pillar of Social Rights*

Lastly, the European Platform on Combating Homelessness has introduced a series of actions to ensure meaningful progress in the efforts of Member States to combat homelessness.

Objective 10 of the Sustainable Development Goals (SDGs) emphasizes the need to reduce inequality both within and among countries. This commitment begins with the elimination of all forms of discrimination, as articulated in various Declarations of Rights. A pertinent example is the Charter of Fundamental Rights of the European Union which prohibits discrimination on several grounds, including disability. Specifically, target 10.2 seeks to "empower and promote the social, economic, and political inclusion of all, irrespective of disability."

Disability often constitutes a unique vulnerability, exacerbated by legislative frameworks that have historically denied legal capacity to individuals with mental or psychological impairments. Recognizing legal capacity is essential for achieving target 10.3, which focuses on ensuring equal opportunity and reducing inequalities in outcomes. This includes eliminating discriminatory laws and practices while promoting appropriate legislative measures.

The Convention on the Rights of Persons with Disabilities (CRPD) marked a significant advancement in recognizing disability as a human rights issue on a global scale. The Preamble of the CRPD underscores the importance of individual autonomy and independence for persons with disabilities, emphasizing their right to make personal choices. The Convention defines persons with disabilities as those who experience long-term physical, mental, intellectual, or sensory impairments, which may hinder their full and effective participation in society due to various barriers.

The CRPD obligates signatory states to "promote, protect, and ensure the full and equal enjoyment of all human rights and fundamental freedoms by all persons with disabilities, and to respect their inherent dignity." Notably, Article 12 of the Convention mandates that states recognize that persons with disabilities enjoy legal capacity on an equal basis with others in all aspects of life and that they are entitled to the support necessary to exercise this capacity, accompanied by safeguards that respect their rights, will, and preferences.

Furthermore, SDG 9, which focuses on building resilient infrastructure, promoting inclusive and sustainable industrialization, and fostering innovation, is particularly relevant to industrial property regulations, specifically patents. Targets 9.4 and 9.5 advocate for specific adaptations within the regulatory framework of industrial property to facilitate innovation and sustainable industrial practices.

SDG 12.a calls for support to developing countries to enhance their scientific and technological capacities towards more sustainable consumption and production patterns. This necessitates robust protection of exclusive rights, along with the flexibility and speed required for fostering innovation and research. Industrial property rights are enshrined in Article 17(2) of the Charter of Fundamental Rights of the EU, and numerous Directives reflect the significance attributed to these rights.

The EU's legislative framework regarding industrial property is largely encapsulated in the European Patent Convention, established on October 5, 1973, and the Directive 98/44/EC on the legal protection of biotechnological inventions, enacted on July 6, 1998.

Regarding SDG 3, specifically target 3.8, which aims to achieve universal health coverage—including financial risk protection and access to quality essential health care services—there are EU regulations that address patent systems to support disadvantaged countries. Notably, Regulation (EC) No 816/2006 outlines the framework for the compulsory licensing of patents concerning the manufacture of pharmaceutical products for export to countries facing public health challenges. This Regulation aims to alleviate public health problems in least developed and other developing countries by improving access to safe, effective, and affordable medicines, ensuring their quality is guaranteed.

The rule of law is essential for the effective functioning of any society. Despite its universal importance, it remains a complex and multifaceted concept, interpreted and applied in diverse ways. This contribution delves into the intricacies of the rule of law, focusing on its role as a foundational value in the European Union's (EU) political and legal framework. It seeks to address the challenges associated with educating students on the core components of the rule of law and proposes effective teaching methods for enhancing their understanding.

Figure 4: *Fighting for Human Rights: Social Entrepreneurs Advocating for Equality and Justice*

The Complexity of the Rule of Law.

1. Empowering Marginalized Communities: Kiva.

Kiva is a pioneering social enterprise that facilitates global connections through micro-lending. By providing small loans to entrepreneurs in underserved communities, Kiva enables them to start or expand businesses, lifting themselves and their families out of poverty. This approach fosters economic development and empowers marginalized individuals to achieve self-sufficiency, actively participating in their local economies.

2. Promoting Education for All: Teach for All.

Teach for All is a global network of social enterprises dedicated to providing quality education universally. By recruiting and training talented young leaders as teachers, Teach for All addresses educational disparities and empowers students to reach their full potential. Through innovative teaching methods and community engagement, these initiatives are transforming children's lives worldwide, fostering a more equitable and just society.

3. Breaking the Cycle of Poverty: BRAC.

Originally founded in Bangladesh, BRAC is now among the world's largest development organizations, exemplifying effective social entrepreneurship. With a holistic approach to poverty alleviation encompassing education, healthcare, microfinance, and social empowerment, BRAC empowers individuals and communities with resources and skills to break the cycle of poverty, fostering inclusivity and sustainable progress.

4. Advocating for Gender Equality: Global Fund for Women.

The Global Fund for Women is a leading advocate for women's rights globally. Through grants to grassroots organizations and activists, it supports efforts to combat gender-based violence, promote economic empowerment, and ensure women's full participation in decision-making processes. These initiatives drive systemic change toward a more equitable world.

5. Protecting the Environment: Patagonia.

Patagonia, a renowned outdoor company and certified B Corporation, leads in environmental stewardship. Through initiatives like donating 1% of sales to environmental causes via the 1% for the Planet program, Patagonia showcases how social entrepreneurship can mitigate ecological impact and advocate for climate justice.

6. Providing Access to Clean Water: charity: water.

Charity: water revolutionizes global water access by funding sustainable projects in developing nations. Through transparent practices and accountability, it ensures communities gain reliable access to clean drinking water, inspiring a new generation of social entrepreneurs to address urgent global challenges.

7. Fighting Food Insecurity: The Hunger Project.

The Hunger Project mobilizes a global movement to end hunger and poverty. By empowering communities with sustainable solutions and strategic partnerships, it enables self-reliance and tackles the root causes of food insecurity, exemplifying the transformative power of social entrepreneurship.

8. Promoting Accessible Healthcare: LifeSpring Hospitals.

Life Spring Hospitals in India innovatively provides affordable, quality healthcare to underserved communities. Through a sustainable business model, it demonstrates that healthcare can be accessible and financially viable, improving health outcomes and reducing disparities.

9. Supporting Fair Trade: Ten Thousand Villages

Ten Thousand Villages is a nonprofit promoting fair trade by empowering artisans worldwide. It provides market access and ensures fair wages, enabling artisans to build sustainable livelihoods and raising awareness about ethical consumerism.

10. Empowering Refugees: Re

Empowers refugees through skills training and employment opportunities. By harnessing refugees' talents and fostering integration, Re

challenges stereotypes and promotes inclusivity, showcasing the transformative impact of social entrepreneurship.

These examples highlight how social entrepreneurship addresses critical societal issues, promoting equality, justice, and sustainability to create a more inclusive global community.

The rule of law transcends mere compliance with legal rules; it embodies the principle that law governs everyone, including the state and its citizens. Its primary rationale is to safeguard individuals from arbitrary power, ensuring that governmental authority is limited and accountable. Given its context-dependent nature, the interpretation of the rule of law varies based on historical, geographical, and cultural factors. Consequently, while the concept of the rule of law is globally recognized as essential, various approaches—such as formal versus substantive interpretations—have emerged, influenced by differing compliance levels with the rule of law.

Formal vs. Substantive Rule of Law.

The formal dimension emphasizes adherence to legal norms and the characteristics of law itself, including clarity, stability, and non-contradictory rules. This aspect is crucial for the functioning of political systems and underpins civil and political rights fundamental to democracy. However, it is essential to recognize that a robust rule of law does not automatically equate to a healthy democracy. For instance, democracies can still exhibit significant deficiencies in their rule of law—exemplified by Hungary's 'illiberal democracy'—while established democracies may also face rule of law challenges.

In the EU, the rule of law stands as a cornerstone of its political and legal order, serving as both a guiding principle and a measure of member states' adherence to democratic norms. Recent developments, particularly instances of rule of law backsliding in certain member states, have highlighted the EU's unique challenge of safeguarding this foundational value against systematic violations. This situation creates an imperative for educators teaching the rule of law within the context of EU values, necessitating effective communication of the importance and implications of the rule of law to students.

Educational Approaches to Teaching the Rule of Law:

1. Pedagogical Framework.

The contribution emphasizes the need for a comprehensive pedagogical framework that encompasses the complexity of the rule of law. Educators should adopt a multidimensional approach that integrates historical, theoretical, and practical perspectives, allowing students to appreciate the nuances of the rule of law in various contexts.

2. Methodological Strategies.

Methodological tools for teaching should be tailored to promote active learning and critical thinking. This could include case studies that illustrate real-world applications and challenges of the rule of law, simulations of legal processes, and discussions that encourage students to analyze and debate contemporary issues surrounding the rule of law.

3. Interdisciplinary Perspectives.

Integrating perspectives from political science, sociology, and ethics can enrich students' understanding of the rule of law. This interdisciplinary approach enables students to grasp how the rule of law intersects with broader societal values and the impact of political structures on legal frameworks.

Abstract

The article is devoted to the comparative analysis of regional economic policy conducted in developed countries and in Russia. The processes of development and realization of the regional policy of developed countries are investigated, which include the correct choice of objects for which the stimulation or restriction of economic growth is envisaged. It is noted that the market processes of the 90s of the last century in Russia took place against the background of economic crisis, accompanied by a decline in the standard of living of society, the growth of the differentiation of the country's regions in terms of socio-economic development, which contributed to the emergence of depressive territories. The important components of the concept of "depressive region" are considered, as well as the established subtypes of depressive regions are presented, their features are highlighted. It is noted that the depressiveness of regional development had a direct dependence on the sharp decline in living standards in the years of market transformation. On the example of such a depressive region as the Chechen Republic the analysis of successful implementation of government measures to achieve sustainable socio-economic development of the region is carried out.

Keywords: regional policy, sustainable development, income, employment, Chechen Republic

I. Introduction

In modern domestic economic science there are different ideas regarding the definition of the content of regional policy. Thus, the regional policy conducted under the conditions of centralized management system in the Soviet Union, pursued the global goal of placing productive forces, solving the problems of creating large territorial-production complexes, accelerated development of the eastern regions, development of northern territories, equalization of the levels of economic development of the Union republics, etc. The nationwide character of this policy was its principal feature. The realization of national tasks, taking into account the location of the resource base and socio-economic characteristics of the country's territories was the main core of its content. [1]

Regional policy in foreign countries had some differences, providing for differentiated diagnostics of the country's economic regions in order to determine the directions of development. Along with the solutions of economic problems, considerable attention was paid to the problems of social, political and environmental nature, and although economic motives were given the greatest importance, their relative importance could be different depending on the country. It should be noted that it was only in the late 1950s and early 1960s that European countries began to emphasize economic issues in their regional economic policies, whereas previously the prerogative had been given to its social importance. In modern times, social factors play no less important role and their goal is to achieve full employment, to distribute the regional income received and to solve the problem of welfare [1].

II. Methods

According to S.S. Reshiev, in the development of effective policy much depends on the choice of the state strategy for the development of raw material industries and the form of ownership of them, as they represent the economic core that contributes to the successful economic growth of all regions.

In the work of Surkov S.A. and Shusharin V.V. it is noted that equalization of the levels of economic and especially social development of regions, which have far from equal opportunities, will contribute to leveling the processes of depressiveness of regional development.

N.D. Kondratiev considered it necessary to rely on a comprehensive study of regularities and trends of movement in the past and the possible direction of changes in the future, in contrast to the widespread teleological approach, which focuses on a priori set goals and predicts possible ways to achieve them.

Smirnyagin L. and Bylova G. note that the experience of Western countries facing the problem of structural reorganization and withdrawal from the crisis of depressed regions indicates a higher efficiency of the path of development aimed "upward" and the use of internal growth factors.

According to Volkov and other researchers, among the most conflictogenic factors influencing the socio-political and inter-ethnic situation in the North Caucasus, it was the factors of religiosity that stood out, and their role will not diminish given the unfavorable socio-economic situation.

According to the research of R.M. Sadykov, the growth of the physical volume of gross output of the personal sector was due to the inflow of labor force released from agricultural enterprises, land reform, which removed restrictions on the size of personal land use and livestock, etc.

In conducting this scientific research, such scientific methods as the method of comparative analysis, statistical analysis, comparative analysis, functional analysis, positive and normative analysis were applied. The scientific research was carried out in accordance with the problem-chronological principle, the principles of systematicity, as well as scientific objectivity.

III. Results

Regional economic policy or local planning absorbs all types of government intervention to improve the territorial distribution of economic activities. In fact, regional policies implemented in foreign countries seek to correct some spatial effects of free trade economy in order to achieve economic growth and improve the process of social distribution.

There are five periods in the development and implementation of regional policies of foreign countries:

- the first period is to identify regional problems and their origins;
- the second period is the definition of objectives and, if possible, in a quantitative way;
- the third period is the formation of an appropriate strategy;
- the fourth period is the selection of instruments to be used;
- the fifth period is the evaluation of the implemented policy [1].

Among the most important elements of the process of development and implementation of regional policy of developed states is the correct choice of objects for which it is envisaged to stimulate or limit economic growth.

During the realization of market transformation in Russia there was a deep recession in the economy, a decline in living standards of the population, increased differentiation of regions by level of socio-economic development, which resulted in the emergence of depressed territories. By the beginning of the XXI century, as a result of transition processes, 2/3 of the country's subjects, especially those located near or on the periphery of such leading industrial centers as the North-Western, Central, Volga-Vyatka, Volga economic regions, as well as the North Caucasus, Siberia, the Far East and the Urals were presented as depressive [2].

Depressiveness as an economic phenomenon in relation to the regions, according to the “theory of long waves” of N.D. Kondratiev, is presented as an objective consequence of the cyclical nature of their economic development [3]. “Depression” as an economic category is a stagnation in the economy, with a lack of growth in production and business activity, low demand for products and significant unemployment. This phenomenon is usually observed after or as a result of an economic crisis, indicating the final stage, after which we should expect the onset of the stages of economic recovery and recovery. Based on the existing ideas of both domestic and foreign economic theory, depression is characterized by a cumulative process, when the reduction of investment and consumer demand results in a decrease in production and production resources, thereby maintaining low demand [4].

It should be noted that the Russian depression, emphasizing its specificity in the form of a decline in production in the presence of inflation, gave reason, according to some authors, to consider it as “stagflation.” [2] In accordance with this context, “depressive region” is most accurately defined by L. Smirnyagin and G. Bylova as a territory that differs from others in terms of the main socio-economic indicators, which include the rate of development. [5]

At the legislative and regulatory level, the concept of “depressed regions” found application in the context of budgetary relations to determine the system of compensation for existing interregional differences. In the Resolution of the Government of the Russian Federation No. 639 dated 29.06.1995, the name “depressive” was first adopted in relation to the regions, despite the ambiguity of its interpretation, which in the future, especially in practice, had negative consequences. The draft Federal Law No. 91010-3 “On the Basis of Federal Support for Depressed Territories of the Russian Federation” adopted in the country on March 12, 2003 reflected the concept of “depressive region” more precisely. According to this provision, “depressed territory” was represented as a unit in the form of a district, city or it was a set of contiguous administrative units with a homogeneous economic structure, within one or more subjects of the Russian Federation, which due to the crisis was in a state of extreme economic decline [6].

In the traditional perception, a depressed region is characterized by a lower than average level of socio-economic development in the country, but in the earlier period it was a relatively stable developing territory, occupying high positions in the country by some indicators. Depressive regions, having a large accumulated scientific and technical potential, a significant share of industry in the structure of the regional economy, a fairly high level of qualification labor resources, while being characterized by decreased competitiveness in the main products, reduced investment demand, negative structural changes in the economy, depletion of mineral raw material base, low indicators of well-being of the local population. Such features define a depressed region as a territory in a phase of steady economic decline, in which there is no possibility of new stimuli for development and it is necessary to apply corrective measures on the part of the authorities to get out of the current state. In the 1990s, depressed regions, based on the duration and depth of territorial depression, largely due to the sectoral specifics of production, the crisis in which led to the spread of depression to the entire regional economy, began to be divided into old-industrial, extractive and agrarian-industrial types [2].

Among the more affected due to the reforms of the 1990s in the country were the old-industrial regions, on the territory of which were concentrated such enterprises of processing industry with a developed scientific, technical and technological base, belonging to the military-industrial complex, machine building, instrument making, light and food industries. The structure of the economy of these territories was formed throughout the period beginning from the late XIX century to the middle of the XX century, with different stages of industrial development [2].

The extractive depressive regions included localized resource-producing territories, especially mining and timber industries, located in sparsely populated areas. These regions, as well as old-industrial ones, were characterized by a fairly developed economic potential with a significant share of industry in the economic structure, highly skilled labor resources, but due to the disruption of supply and raw material relations or changes in the development strategy, as well as the low competitiveness of core industries had problems in the form of deep economic recession, high unemployment, especially structural unemployment, rather low indicators of investment activity of the level of financial and budgetary support of the economy. Depressive regions of the old industrial and extractive types belonged to the group of low-income regions with high poverty rates according to the level of per capita purchasing power of money incomes.

IV. Discussion

Regions of the Central Black Earth Economic Region, republics of the North Caucasus and South Siberia, where stagnation of socio-economic processes was noted as a consequence of a combination of typical agrarian specialization and industrial backwardness of the region, could be attributed to the number of agrarian-industrial depressive regions, despite some difficulties in classification due to the fact that the agricultural sector in most Russian subjects, neither in terms of production volume, nor in terms of share in the gross regional product, did not occupy leading positions [2].

It should be noted that in addition to the above classification of depressed regions, there were others. Thus, in 2005 the Ministry of Regional Development of the Russian Federation developed a new typology of Russian regions, in which all subjects, based on the basis of development, the degree of involvement in global development processes such as globalization, urbanization and neo-industrialization, were grouped into 4 main types and 7 groups based on expert assessment with the analysis of indicators of socio-economic development of the subjects of the Russian Federation. In depressive regions, according to this classification, there was a significant economic decline in the main branches of the economic sphere over the last 10 years and lower level compared to the average analogs in the country of many economic indicators, while in the past these territories were economically developed, occupying prominent places in some positions in the country's economy [7].

In general, in depressed regions there were observed:

- high unemployment rates and, as a consequence, a low standard of living of the population living in these territories;
- significant lag in socio-economic development compared to other regions of the country;
- poor infrastructure provision.

In turn, depressive regions were subdivided into such subtypes as background and crisis. While the background depressive regions had a low standard of living, backward technological base, insufficient market positioning, and a shortage of human resources, the crisis regions were characterized by a rather significant lag behind other regions in terms of socio-economic development, high unemployment rates, poor infrastructure provision and a higher level of social conflicts. Depressiveness of regional development had a direct dependence on the sharp decline in living standards during the years of market transformation.

At the beginning of 2000, the Chechen Republic could also be considered as depressive among the Russian regions that were among the last in the country in terms of socio-economic development, which is confirmed by the data in the table below.

Table 1: *Main socio-economic indicators (2005 results)*

Key indicators	Number of registered unemployed in % of economically active population	Area of housing stock per capita	Industrial output per capita, thousand rubles.	Share of pupils studying in the second shift, %	Number of hospital beds Number of hospital beds per 10,000 people.	Proportion of population with incomes below the flow minimum
Russian Federation	2,6	19.2 (18 is the norm)	78,1	19,8	116,0	17,8
Southern Federal District	5,9		24,8	25,2	105,2	37,3
Chechen Republic	78,9	11,7	9,7	54,8	68,9	90,0

Analysis of the data in the table shows that the Chechen Republic lagged far behind in all the most important socio-economic parameters in comparison with the all-Russian average and the average for the Southern Federal District (SFD), of which it was then a part. For example, by the end of 2005, the regional indicator of the number of registered unemployed was more than 30 and 13 times higher than the national average and the average for the Southern Federal District, respectively; the share of the population with incomes below the subsistence minimum was more than 5 and 2 times higher than in the country as a whole and in the Southern Federal District, respectively, etc.

The reasons for this negative socio-economic state of the Chechen Republic were to be found in the political and economic restructuring that began in the USSR and the anti-terrorist operations of the last decade of the 20th century, which resulted in the final destruction of the regional economy. The economic crisis in the republic began even before the anti-terrorist operations began, with the rise to power of new persons whose aims were far from the interests of the Chechen people. While the pre-war economic crisis was manifested by a decline in production and living standards, rising unemployment and crime rates, during the anti-terrorist operations many of the region's industrial and social infrastructure facilities were virtually destroyed.

The unemployment rate in the republic, which by the mid-2000s reached about 80% of the able-bodied population, was the highest compared to other regions of the country, and the situation was aggravated by the fact that there were positive dynamics of demographic processes due to the growth of the birth rate, as well as the return of refugees and forced migrants to their homeland due to the cessation of anti-terrorist operations. By the beginning of 2005, according to the data of the Ministry of Labor of the Republic, the number of unemployed able-bodied population reached 400 thousand people, i.e. 62% of the labor resources and almost 69% of the economically active population of the region. This situation, in which the labor market in the republic found itself, could be generally considered as a crisis. In August 2005, at a meeting of the Government, when approving the draft federal budget for 2006-2008, German Gref pointed out that 91% of the population of the Chechen Republic was officially below the poverty line. At the same time, according to the minister, in the Khanty-Mansiysk and Yamalo-Nenets Autonomous Okrugs this indicator was the lowest in the country - less than 7%, and the main reason for the extremely low incomes of the region's population was unemployment [9].

It is worth noting that the deficit of jobs was the most pressing problem for all regions of the Southern Federal District. This was especially true for the republics in which the number of working-age population was two to three times higher than the number of available jobs. In all the republics of the North Caucasus, the load of the unemployed population per vacancy was significantly higher than the national average. Thus, in 1999 in Ingushetia this indicator reached 184.4 people, in Dagestan ◎ 32.3, 20.3 ◎ in Kabardino-Balkaria, while the all-Russian ◎ 2.4 people per vacancy [10].

One of the sides of this problem for the Southern Federal District was the employment of graduates of higher educational institutions. Thus, in 2004, when analyzing the need for specialists with higher education it was revealed that for the last five years the labor market annually increased by about one hundred thousand only at the expense of university graduates, and most of them had humanitarian and socio-economic specialties, thereby worsening the already difficult situation in the sphere of employment of specialists of higher and middle levels. Thus, for example, in 2003 state and non-state higher education institutions of the Southern Federal District graduated 38.2 thousand people in these specialties, while the demand for them, according to the data of employment services, was only 14.5 thousand people. In some regions the spread was even higher: 9 times the excess was reached in Karachaevo-Cherkessia, 7 times in ◎ Ingushetia, 4 times - in Rostov region [11].

In the mid-2000s, the Chechen Republic lagged 7-8 times behind the Russian average in terms of per capita income. At the same time, the consumer market was only one-quarter supplied with local goods, and therefore the increase in incomes, including through allowances and compensatory payments, did not sufficiently stimulate the growth of production in the republic, and at the same time, despite the low incomes of the population, the cost of living here was noticeably higher. [11] Thus, in the 4th quarter of 2005, the minimum subsistence level for this region was set at 2793 rubles, which was slightly more than the size of the pension for disabled people of the second degree and noticeably lower than the subsistence level even in comparatively poor and small Ingushetia, while the average per capita income of the Chechen Republic was 512 rubles. And more than a third of Chechen families had to live on such an income [12].

Various social transfers such as pensions, allowances, compensations, etc., assistance from relatives, and income from subsidiary and personal homestead farms were of great importance in ensuring the livelihood of households in the region in the face of high unemployment in the period under consideration. Support from relatives, mostly from those who had managed to find good jobs outside the republic, both in other Russian regions and abroad, was also an important source of survival. As is well known, kinship ties are highly valued in Chechen society, and close ties with parents remain with children until the end.

As we have already mentioned earlier, employment in subsidiary and personal household farms contributed to the survival of the region's population. It should be noted that in the conditions of fragmentation and changes in the existing production structures, personal subsidiary (household) farms of rural residents begin to acquire great importance as a source of agricultural products and concentration of a significant part of production resources and activities. Personal subsidiary farms become for many rural residents the only way of life support and livelihood. Thus, according to researchers' calculations, if properly managed, a plot of land of 6 hectares can provide a family of four people with vegetables, potatoes and fruit and vegetable products, in this regard, the training of rural residents, especially young people, agricultural knowledge and improving the culture of agricultural production are considered as an important direction of social policy in rural areas. [13] Personal subsidiary farms are more resilient and adapted to the market compared to large-scale production. In conditions of economic crisis, home agricultural production is beginning to play an important role in the survival of the majority of not only rural but also urban residents.

On February 19, 2007, in the session hall of the Ministry of Finance of the Chechen Republic in the framework of the round table entitled "A New Economic Strategy for the Chechen Republic", it was pointed out that it was necessary to elaborate and start implementing a long-term development program for the republic based on the current socio-economic situation. Employment growth was the main condition for increasing the population's income, which, in turn, was impossible without the corresponding development of production and social infrastructure. Of great importance in improving the quality of life and the development of many industries, especially those based on the use of natural resources (oil production, agriculture, forestry, tourism, recreation) was the need to restore the natural environment and its protection [14].

The implementation of program activities in accordance with the planned goals and objectives allowed the leadership of the republic to increase real incomes of the population by the end of 2010 in 1.3-1.5 times, nominal average monthly accrued wages - in 1.7 times, the level of officially registered unemployment decreased by 2 times compared to 2005 [15].

The Russian Federation Government Resolution of April 15, 2014 approved the state program "Development of the North Caucasus Federal District until 2025", the main purpose of which was to improve the welfare and quality of life of the population of the republics that make up the North Caucasus Federal District, ensuring the reduction of their lagging behind the average Russian level

Necessary for the solution of this problem was the formation of a dynamically developing and competitive economy, which, in turn, provided for:

- increasing investment activity and attractiveness of the republics of the North Caucasian Federal District;

- formation of modern tourist infrastructure of tourist-recreational special economic zones on the territories of the republics of the North Caucasus Federal District, Krasnodar Krai and the Republic of Adygea;

increasing the number of beds in collective accommodation facilities in such a specially protected ecological resort region of the country as Caucasian Mineral Waters;

- creating new jobs in competitive sectors of the economy and reducing the unemployment rate;

- ensuring an increase in the population's monetary income and reducing the unemployment rate;

- modernization of health care, education, social protection and social services;

- Ensuring accessibility of medical care for the population at all stages and preschool education services;

- creating conditions for increasing the birth rate and life expectancy of the population, increasing the share of students studying in the first shift in general educational organizations. [16]

In general, it should be noted that the state measures to achieve sustainable socio-economic development of the region, taken within the framework of the noted program can be considered effective. Thus, the gross regional product in 2022 amounted to 268068,5 million rubles, which exceeded the 2005 figure by more than 11 times; the gross regional product per capita increased from 20038,4 rubles in 2010 to 177859,9 rubles in 2022, i.e. by almost 9 times; the volume of agricultural production in 2023 amounted to 50861,0 million rubles, which was more than 11 times higher than in 2005; investments in fixed assets increased 9 times since 2005, reaching the mark of 119515.31 million rubles; the number of officially registered unemployed from 332.7 thousand people in 2005 decreased to 51.8 thousand people in 2023, i.e. by 84%. [17] Based on the world experience, it can be noted that significant economic successes are achieved only by such territories, in which management mechanisms based on the principles of social justice, pursue the goal of creating equal conditions for sustainable human development, contribute to the development of his intellectual and physical abilities, the growth of the quality of life of the population as a whole.

Abstract

Carbon polygons are areas where data are collected and accumulated to assess the carbon balance of ecosystems, as well as to implement measures to reduce carbon emissions and increase the absorption of greenhouse gases (GHGs). They play an important role in the context of the global fight against climate change, providing important information for improving the management of carbon cycles. However, their impact on local ecosystems is complex and multifaceted. The interaction of carbon polygons with the surrounding nature can vary from positive (e.g. restoration of biodiversity, improvement of soil and water conditions) to negative (including changes in vegetation structure, disruption of usual animal migration routes and possible displacement of local species). This paper considers the key ecological aspects of the functioning of carbon polygons, their interactions with local ecosystems, as well as possible socio-ecological consequences, including both environmental benefits and potential threats to biodiversity and the resilience of natural systems.

Keywords: carbon polygons, carbon balance, climate change, local ecosystems, biodiversity, greenhouse gases, ecosystem restoration, ecosystem services

I. Introduction

More than 160 countries around the world have committed to achieving carbon neutrality by 2030-2070 in one form or another. 1 The goal of achieving carbon neutrality no later than 2060 is formulated in the Climate Doctrine of the Russian Federation. However, many decarbonization plans lack specificity. As a result, they are being implemented too slowly, faced with increasing protectionism, complicated geopolitical problems (security, reliability of supply chains), which prevents the necessary pace of progress towards carbon neutrality. 2 In order for decarbonization actions to be understandable, coordinated at all levels of decision-making and implementation, and to receive broad public support, a clear and understandable action plan is needed - a roadmap - to transform the current raw materials model of economic and socio-political development of Russia into a model of an inclusive and fair innovative low-carbon economy.

The pilot project to create a network of carbon polygons in the Russian Federation is aimed at fulfilling the tasks within the framework of the national action plan for adaptation to climate change and ensuring environmental safety. The main goal of the project is to study the processes of emission and absorption of greenhouse gases (GHG) and develop technologies that help reduce their concentration in the atmosphere. Carbon polygons are experimental territories where comprehensive studies are carried out aimed at assessing the carbon balance of ecosystems and implementing solutions to reduce GHG emissions and increase their absorption.

The main objectives of the project:

1. Monitoring greenhouse gas emissions and absorption:

One of the key functions of carbon polygons is to monitor emissions and absorption of GHGs (carbon dioxide, methane, and others). Ground-based and remote measurement methods are used, such as installing sensors, detectors, and using satellite data. This helps to monitor the dynamics of carbon flows and identify sources and sinks of GHGs in different types of ecosystems.

Global carbon dioxide levels as of…

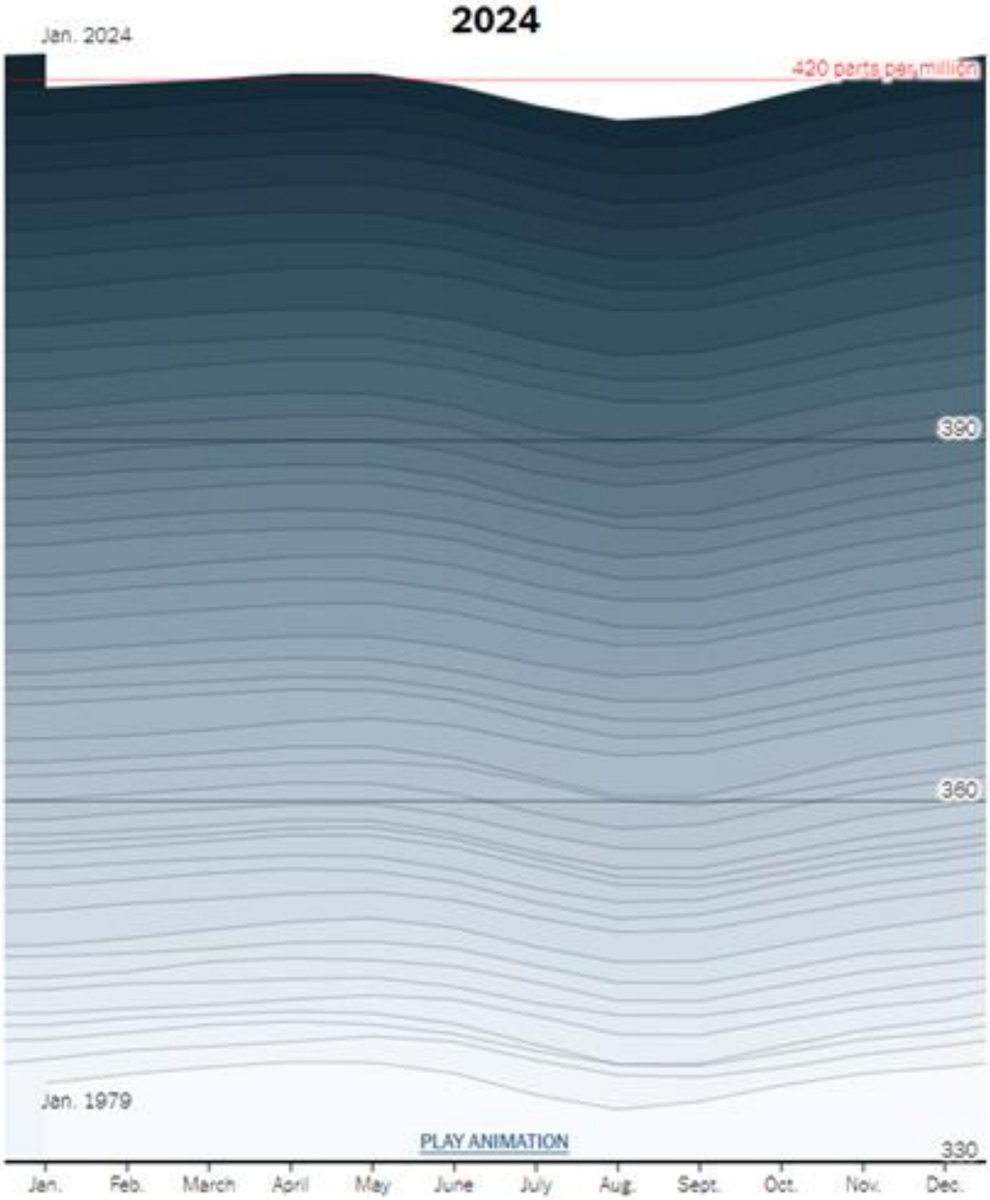

Figure 1: *The chart shows monthly numbers of carbon dioxide molecules per million molecules of dry air. Because of seasonal differences, levels are higher in May than in August.*

2. Assessment of spatial and temporal variability of carbon fluxes:

Regular measurements are taken at landfills to determine the spatial and temporal dynamics of carbon emissions and absorption. These data allow the creation of integrated carbon balance models, assessing how these flows change depending on the season, time of year, weather conditions and landscape features. As a result, conclusions can be drawn about how differences in climate and geography can affect the carbon balance of various ecosystems.

3. Development of technological solutions to reduce emissions and increase absorption of greenhouse gases:

One of the project's priorities is testing and verification of technologies aimed at reducing emissions and increasing absorption of GHGs by natural ecosystems. Such technologies include forest restoration, regulation of agricultural practices (e.g. minimizing the use of fertilizers and improving agricultural practices), water and soil management. In addition, polygons are used to test these technologies under conditions close to real ones and verify their effectiveness in different climate zones and ecosystems.

4. Development of technologies for remote monitoring of ecosystems:

To manage carbon flows, it is necessary to develop technologies for remote monitoring of the structure and condition of ecosystems (vegetation and soil cover, soil moisture, biomass). This is achieved by synthesizing ground-based measurement data with the results of satellite observations and mathematical modeling. The use of such technologies will allow for prompt assessment of the condition of ecosystems and forecasting changes in the carbon balance.

The carbon landfill project proposed by Ctrl2Go is a key initiative to address Russia's unsustainable production and reduce greenhouse gas emissions. With limited government resources to develop their own solutions, business participation is becoming a strategically important step. Ctrl2Go has provided a technology that can not only reduce Russia's gap in the green economy, but also make it one of the leaders in this field. With the European Union introducing a carbon tax from 2023, Russia faces additional challenges amid an economic crisis exacerbated by the COVID-19 pandemic. The carbon landfill project provides an opportunity to minimize risks to the economy and avoid a protracted crisis that could arise due to the complication of trade relations with the EU.

The authors of the project emphasize that carbon landfills are the only fast and effective way for Russian enterprises to reduce greenhouse gas emissions. This is a preferable way compared to the proposal to introduce taxes on excess carbon dioxide emissions, which, according to the authors, will not solve the problem of polluting industries, but will only increase the burden on them. The technology developed by Ctrl2Go is capable of providing real mechanisms for monitoring and reducing emissions, which makes this project a viable alternative to tax measures.

The scientific component of the project also plays an important role. Russia, which has long relied on traditional fuels such as oil and gas, risks falling behind in the field of new energy sources, which will negatively affect its industry and energy sector. Carbon polygons allow not only to implement emission control technologies, but also to create a scientific complex for automated measurement of the level of carbon dioxide absorption in various natural zones of the country. This is especially important in the context of international climate agreements and requirements. The European Union uses closed methods for calculating the carbon footprint, which take into account only the level of emissions, but do not take into account the absorption of carbon dioxide by nature. The carbon polygon project will allow Russia to develop an alternative system for assessing the carbon balance and propose its own adjustments to the international practice of calculating carbon duties, which will strengthen its position in international negotiations.

II. Methods

Carbon landfills are currently being considered as a possible tool to combat the effects of climate change. Their main advantage is that they can improve air quality by capturing and storing carbon dioxide emitted by industrial plants, which is especially important near large emission sources. These landfills also have the potential to reduce the amount of carbon dioxide released into the atmosphere, which helps slow global warming. In addition, the development of this technology can stimulate economic growth and create new jobs.

However, carbon landfills also have their drawbacks. Their implementation requires significant financial costs, which can become a serious barrier to large-scale use. It is also worth considering that the technology is still in the development stage, and there are many technical problems that need to be solved. In addition, the ability of carbon landfills to capture carbon dioxide is limited, and their effectiveness on a global scale remains questionable. Overall, despite the existing difficulties, carbon landfills play an important role in studying the mechanisms of CO_2 absorption by natural ecosystems and can become a significant element in the fight against climate change.

III. Results

The need to combat climate change remains important at the global level, and Russia continues to actively develop climate policy. Data on greenhouse gas (GHG) emissions and absorption play a key role, as they are used to formulate climate goals, compile country and company reports, implement climate projects, and develop carbon markets. However, the quality of this data is still far from ideal. According to the IEA, the uncertainty in estimates of global carbon dioxide emissions is 10%, methane - 25%, nitrous oxide - 30%, and fluorinated gases - 20%. Also difficult is the assessment of the ability of forests and other ecosystems to absorb carbon, which is of particular importance for the Russian climate strategy.

Russia's climate goal for 2030 is to reduce GHG emissions to 70% of 1990 levels, taking into account the maximum absorption capacity of forests and other ecosystems, subject to sustainable socio-economic development. Currently, absorption compensates for about 30% of GHG emissions in the country. The assessment methodology is based on recommendations from the Intergovernmental Panel on Climate Change, but discussions about the accuracy continue.

In February 2022, Russia approved the Federal Program for Environmental Development and Combating Climate Change until 2030, which includes the creation of a system for monitoring GHG flows and the carbon cycle. The law on limiting GHG emissions adopted in 2021 obliged large emitting companies to submit emissions reports and opened up opportunities for climate projects.

The report analyzes the role and current state of the carbon landfill network in Russia, including goals, objectives, regional characteristics, results, scientific research, technologies, educational programs and international cooperation.

IV. Discussion

Global averaged concentrations of carbon dioxide (CO2), the most important greenhouse gas, in 2022 were a full 50% above the pre-industrial era for the first time. They continued to grow in 2023.

The rate of growth in CO2 concentrations was slightly lower than the previous year and the average for the decade, according to WMO's Greenhouse Gas Bulletin. But he said this was most likely due to natural, short-term variations in the carbon cycle and that new emissions as a result of industrial activities continued to rise.

Methane concentrations also grew, and levels of nitrous oxide, the third main gas, saw the highest year-on-year increase on record from 2021 to 2022, according to the Greenhouse Bulletin, which is published to inform the United Nations Climate Change negotiations, or COP28, in Dubai.

“Despite decades of warnings from the scientific community, thousands of pages of reports and dozens of climate conferences, we are still heading in the wrong direction,” said WMO Secretary-General Prof. Petteri Taalas. “The current level of greenhouse gas concentrations puts us on the pathway of an increase in temperatures well above the Paris Agreement targets by the end of this century. This will be accompanied by more extreme weather, including intense heat and rainfall, ice melt, sea-level rise and ocean heat and acidification. The socioeconomic and environmental costs will soar.. We must reduce the consumption of fossil fuels as a matter of urgency,” said Prof. Taalas .

Just under half of CO2 emissions remain in the atmosphere. Just over one quarter are absorbed by the ocean and just under 30% by land ecosystems like forests – although there is significant year-to-year variability in this. As long as emissions continue, CO2 will continue accumulating in the atmosphere leading to global temperature rise. Given the long life of CO2, the temperature level already observed will persist for several decades even if emissions are rapidly reduced to net zero.

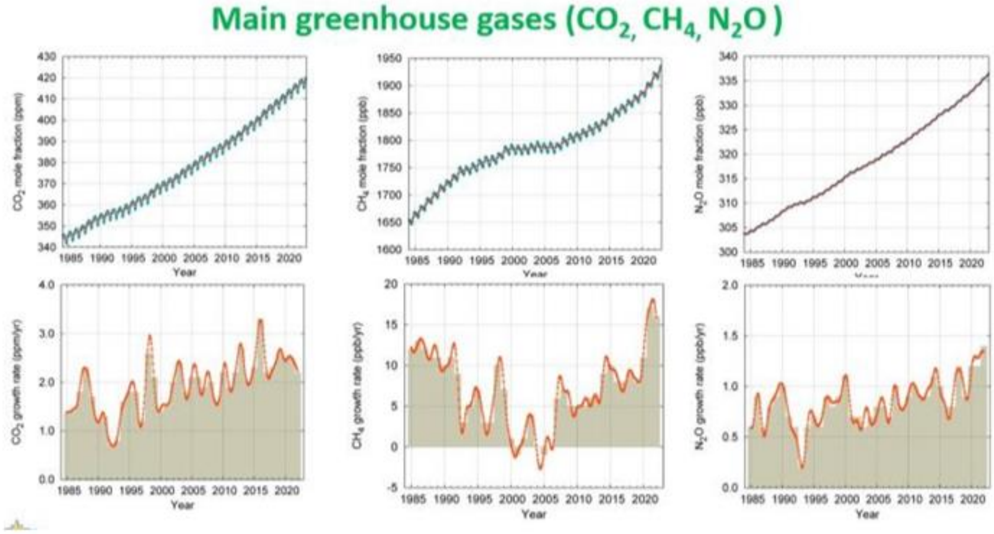

Figure 3: *Graphs - Main greenhouse gases*

The last time the Earth experienced a comparable concentration of CO2 was 3-5 million years ago, when the temperature was 2-3°C warmer and sea level was 10-20 meters higher than now.

The carbon measurement supersite at Kadyrov Chechen State University is distinguished for its scientific research aimed at developing regenerative animal husbandry technologies in mountainous and foothill regions. Regenerative grazing management, especially adaptive grazing across multiple pastures, helps to reduce soil degradation compared to continuous grazing, thereby potentially lowering carbon emissions from the soil. The integration of crop rotation and maintaining perennial cover crops with controlled grazing also contributes to the accumulation of organic carbon in the soil.

This work is being carried out as part of a project to develop a pasture management tool. To achieve these goals effectively, the university collaborates with climate and carbon experts from the Peoples' Friendship University of Russia, the Voronezh State Forestry University, the National Research University Higher School of Economics, the Institute of Geography of the Russian Academy of Sciences, and the Yu.A. Israel Institute of Global Climate and Ecology.

The project aims to identify the most efficient methods of regenerative animal husbandry to enhance carbon sequestration in pastures and study the effects of climate on ecosystems in mountain and foothill landscapes. The planned service will rely on a digital model of pasture sites, enabling the analysis of pasture conditions, degradation, forage production volume, and the detection of soil and grass cover damage, wind and water erosion, and signs of salinization. At each site (reference, intensive grazing, and average grazing sites), aboveground herbaceous vegetation is sampled to evaluate biomass volume and quality. The dominant plant species in each ecosystem are identified. In total, 62 species of vascular plants from 31 families have been cataloged on the southern slope of the Makazhoy Basin.

A mathematical model has been employed as part of the project to account for the physical stabilization mechanisms of soil organic matter. Parameter identification for this model is currently underway at regenerative animal husbandry test sites. The project aims to restore soil quality, increase soil carbon content, improve production profitability by increasing livestock density in the same areas, and reduce production costs through natural pasture restoration.

Figure 4: Carbon Polygon Territories of Kadyrov Chechen State University

Figure 5: *Carbon polygon Way Carbon*

The polygon is unique due to the diversity of landscapes on its territory, including steppe zones, forests and subalpine meadows. This allows for research to be conducted in various natural conditions, making climate research more comprehensive. Each of these zones conducts its own climate research aimed at understanding how different ecosystems respond to changes in the environment.

The key goal of the research is to create conditions for carbon neutrality. This means that scientists aim to ensure that the environment absorbs more carbon than it emits. To do this, strategies are being developed to reduce carbon dioxide emissions and increase its absorption by natural ecosystems such as forests, meadows and soils. Ultimately, this will help combat global climate change and preserve ecosystems.

This excerpt talks about carbon sequestration as one way to achieve carbon neutrality. Carbon neutrality means a balance between the emission of carbon dioxide into the atmosphere and its absorption by natural processes. One effective way to absorb CO_2 is to plant plants with high sequestration potential, i.e. the ability to actively accumulate carbon dioxide from the atmosphere.

Sequestration in this context means the absorption of carbon by plants or soil, which helps to offset CO_2 emissions, and carbon dioxide emissions and absorption are monitored at special landfills to determine how effectively this helps to achieve a carbon balance.

Carbon farms are plots of land where plants with a high potential for carbon sequestration are planted. For example, paulownia and poplar are mentioned as tree species that can actively sequester carbon because they grow quickly and effectively absorb CO_2 from the atmosphere.

Thus, with the help of such projects aimed at increasing the absorption of carbon dioxide, it is possible to offset carbon emissions and get closer to achieving carbon neutrality.

Carbon polygons are an important and promising area in Russia's climate policy. They not only contribute to the creation of a reliable system for monitoring carbon flows in the country's ecosystems, but also increase confidence in Russian climate initiatives, since foreign carbon farms face problems with the reliability of their results. According to the Center for Strategic Research (CSR), the polygons, sharing the goals and objectives of the Ministry of Education and Science of Russia, focus on the practical aspects of their work, including the search for optimal solutions for decarbonization. The presence of industrial partners enhances the practical focus of their activities. Although most Russian carbon polygons are in the initial stages of implementation, by September 2022 they have already achieved some success, especially in the field of education and scientific research.

Most of the current research at the sites is related to the development of scientific and methodological tools for climate monitoring, such as geographic information systems (GIS). The sites emphasize the importance of timely delivery of equipment to intensify scientific work, but most of the necessary equipment in Russia is imported, mainly from the United States. In the context of increasing geopolitical tensions, this creates risks for supplies. According to the Russian Ministry of Education and Science, deliveries continue, but the deadlines have increased, and prices have increased by 20-30%.

The educational activities of carbon polygons are also developing successfully. In 2021–2022, at least seven new educational programs for bachelors and masters were created, existing programs were updated, and new courses were introduced. More than 15 advanced training programs and courses were also prepared. In addition, the polygons actively conduct educational and outreach events.

The most challenging situation at present is international cooperation of carbon polygons, which is extremely important for the recognition of Russian research abroad. There is a breakdown in traditional ties with the West, a transition to more active cooperation within the EAEU and a reorientation towards Asian countries. The Russian Ministry of Education and Science is making efforts to support international cooperation by inviting foreign experts from friendly countries to the Expert Council. The survey showed that polygons almost unanimously recognize the potential for further development in all areas: scientific research, education and international cooperation, and plan to commercialize and scale up best practices in the future. However, they also note the existence of barriers, such as access to technology, funding, infrastructure and administrative difficulties, including difficulties with permitting procedures, lack of standards and unified methods. Among the potential barriers, access to funding and uncertainty with the verification of the obtained data are most often mentioned.

Acknowledgments

The work was carried out within the framework of the state assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 075-03-2021-074/4).

Abstract

The concept of sustainable consumption patterns emphasizes the necessity for individuals and communities to shift towards consumption habits that minimize environmental impact, conserve resources, and support long-term ecological balance. In a green economy, consumer behavior plays a pivotal role in driving the demand for sustainable products and services, which in turn influences production systems and business strategies. This paper explores the intersection of consumer choices and sustainability, investigating how factors such as awareness, values, social influence, and policy interventions impact the adoption of eco-friendly behaviors. By highlighting the barriers to sustainable consumption—such as perceived costs, lack of availability, and knowledge gaps—the discussion delves into how consumers can be empowered through education, incentives, and corporate responsibility to foster a green economy. Ultimately, it advocates for a holistic approach, involving stakeholders across sectors to promote behaviors that support sustainability at both individual and societal levels.

Keywords: sustainable development, consumer behavior, environmental impact, eco-friendly products, resource conservation

I. Introduction

In recent years, the urgent need to address environmental degradation and climate change has driven the shift toward sustainable development and the promotion of a green economy. A green economy prioritizes low-carbon, resource-efficient, and socially inclusive growth. One of the critical elements underpinning the success of a green economy is sustainable consumption, which requires individuals to adopt behaviors and consumption patterns that minimize environmental impact, reduce waste, and conserve natural resources.

Consumer behavior plays a central role in shaping the trajectory of the green economy. The choices that individuals make regarding the products and services they purchase significantly affect the demand for environmentally friendly alternatives, encouraging businesses to innovate and adopt sustainable production practices. However, fostering sustainable consumption is not without its challenges. Numerous factors—such as consumer awareness, economic considerations, cultural norms, and availability of sustainable options—impact individuals' willingness and ability to make eco-friendly choices.

This paper examines the role of consumer behavior in promoting sustainable consumption patterns within a green economy. It explores the drivers and barriers to sustainable consumption, considering how public policies, corporate strategies, and social influences can facilitate the transition to more responsible and environmentally conscious consumption habits. The discussion underscores the need for a collaborative approach that involves governments, businesses, and consumers working together to promote a sustainable future.

By understanding the mechanisms through which consumer behavior can impact the green economy, this research aims to offer insights into how sustainable consumption patterns can be encouraged and adopted more widely. In doing so, it contributes to the broader dialogue on sustainability, emphasizing the importance of individual action as a catalyst for large-scale environmental progress.

Today's consumption is no longer just about using goods and services to meet immediate needs; it has also become a reflection of living standards, a marker of social structure, and a way for individuals to express their identity. In contemporary literature, many definitions of consumption emphasize its social, biological, and psychological dimensions, as well as the factors influencing the satisfaction of human needs. The evolution of consumption, driven by globalization, internationalization, innovation, and the rapid development of a knowledge-based economy, has led to consumption playing not only an important but perhaps a fundamental role, increasingly influencing modern economic processes and growth.

Today, even the youngest family members are becoming active participants in the shopping process, often acting as key advisors and decision-makers, especially when it comes to selecting and purchasing products for family enjoyment, such as modern and high-tech gadgets. In response to environmental degradation, a growing number of consumers are enthusiastic and committed to making significant changes in their daily lives to reduce their ecological footprint. As a result, they make purchasing decisions based on sustainable development principles, fully aware of the impact their choices have on their health and the environment.

Today's consumers, above all, are conscious of the effects of their decisions, largely thanks to greater access to information and active involvement in social life. They are knowledgeable about product quality and the price-to-quality ratio, making more responsible choices in shaping their consumption patterns and asserting their consumer rights. Pro-environmental consumer behavior involves the extent to which consumers engage in deliberate, rational actions to protect the natural environment. This environmentally friendly attitude is a product of knowledge and environmental awareness developed by informed individuals.

Fostering these attitudes and promoting healthy lifestyles in society through awareness-raising is one of the primary goals of education for sustainable development. Current research on the relationship between pro-environmental attitudes and behaviors, as well as the methodology used, requires a modern approach. While much of the literature links consumer behavior with these attitudes, empirical findings remain ambiguous regarding the nature, strength, and direction of these relationships.

Young consumers were selected for this study due to their growing influence and decision-making power within households. They tend to respond more actively to the evolving environment, globalization, and its impact on consumption, lifestyle, and emerging trends compared to other market participants. Understanding their motivations, behavior, and market attitudes can help businesses develop appropriate, innovative marketing strategies and identify the right paths for growth. This will enable companies to stay competitive and offer attractive products or services to new, particularly younger, customers, even amidst rapid changes in consumption patterns and the fast-paced development of mobile technologies and applications.

This article aims to identify the consumer attitudes and behaviors of young people that align with the principles of sustainable consumption. It is divided into three sections: theoretical, methodological, and empirical. The theoretical part explores the concept and essence of sustainable consumption and its link to Fair Trade. The methodological section briefly outlines the research design and sample selection. The empirical section investigates the pro-environmental behaviors of young consumers that can be characterized as sustainable consumption. The article concludes with a summary of key findings and insights.

II. Methods

The research was conducted using a custom-designed questionnaire created by the author, consisting of 50 closed-ended questions focused on alternative consumer trends, including sustainable consumption. The survey was carried out between February 1 and May 1, 2018. One of the challenges was accurately defining the target group, as the term "young consumer" lacks a universally agreed-upon definition in the literature. Different studies define the age range of young consumers in various ways, such as 15-29 years old [Szulce, 2009, p. 637], 15-34 years old [Olejniczuk-Merta, 2001, p. 40], 18-25 years old [Grønhøj, 2007, p. 243], 18-30 years old [Kumar, Kapoor, 2017, p. 218], and 18-35 years old [Phillips, Stanton, 2004, p. 8; Ofosu, Gyanewa, Boadi, 2013, p. 288]. For this study, the population was defined as individuals aged 18-34, in line with Polish literature, where 34 years is considered the end of youth.

Participants were recruited through the "ankietka.pl" platform and social media channels like Facebook, WhatsApp, Messenger, and email. To participate, individuals had to access a specific website containing the questionnaire, which was also shared on specialized forums and the fanpages of universities and private schools. The study focused on young consumers aged 18-34, belonging to Generations Y and Z, who made independent purchasing decisions. Importantly, the research targeted all young consumers, not just those engaged in sustainable consumption. A quota sampling method was applied, with gender and age being the key variables (quotas).

It should be noted that a primary methodological challenge in studying the sustainable behavior of young consumers stems from the non-random sampling approach and the use of an online survey. Incomplete or incorrect responses were excluded (17 cases), and out of the 606 initial questionnaires, 589 valid responses were retained, representing 97.19% of the total sample. These responses were coded, and the data were analyzed using the statistical software SPSS, version 23.

The main objective of the research was to explore sustainable consumption patterns among young Polish consumers. The study aimed to uncover the primary factors motivating young people to engage in sustainable consumption. To this end, three research hypotheses were proposed:

- H1: Sustainable consumption is more prevalent among well-educated young consumers living in large cities.
- H2: Disposable income significantly influences young consumers' positive attitudes toward sustainable development. The higher the income, the more favorable their views on sustainable consumption.
- H3: Young women demonstrate higher environmental awareness than young men, leading to consumer behaviors that are more closely aligned with sustainable consumption principles.

III. Results

The restrictions on both domestic and international transportation during the Covid-19 pandemic led to a significant reduction in travel demand, a near standstill in transportation infrastructure, and numerous serious socioeconomic impacts. On the other hand, reduced transportation activity also meant lower demand for oil and other fossil fuels, which brought environmental benefits, including improved air quality. For example, NO_2 emissions dropped by up to 30%, contributing to enhanced environmental quality (Muhammad et al., 2020). Water quality also improved as a result of people staying home and reducing travel and shipping activities.

However, the pandemic also brought environmental challenges, particularly due to the vast amount of medical waste generated daily. The sudden increase in the use of disposable masks, gloves, and hand sanitizers by millions of people contributed to a surge in waste. Additionally, as household organic waste increased and online purchases required more transportation and packaging, there was a dramatic rise in inorganic waste as well. The environmental consequences of the pandemic, both direct and indirect, continue to raise questions about new strategies and approaches that the global community is exploring to reduce future environmental impacts.

H1: Pandemics have a positive impact on environmental awareness.

Pandemics have had a significant influence on regulatory changes affecting global consumer behavior. At the onset of the Covid-19 outbreak, many countries implemented lockdowns or isolation measures, disrupting normal life and forcing the closure of local businesses. Concerns over product shortages triggered anxiety and led consumers to stockpile essential goods and medical supplies. However, as the pandemic persisted, with new variants emerging, financial instability became more pronounced. This resulted in rising unemployment, inflation, and an economic recession in many countries, all of which have affected consumer attitudes, perceptions, and behavior.

In response, consumers have become more cautious in their purchasing decisions, seeking to balance income and expenditure amid price fluctuations and uncertain wages. A 2021 survey of over 3,000 consumers across 15 countries revealed that the pandemic may have ushered in an era of healthier and more sustainable consumption that could last for the next decade (Accenture, 2021). It is clear that Covid-19 has had a profound impact not only on the global economy but also on the psychology of consumers, leading to notable changes in both short-term and long-term consumption patterns.

H2: Pandemics have a positive impact on consumer attitudes.

Subjective norms play an important role when individuals feel pressure to engage in certain behaviors. In response to unforeseen and potentially dangerous situations, like Covid-19, people often experience anxiety and negative emotions as a protective instinct. When feeling vulnerable, individuals may be more likely to accept negative judgments from others in order to safeguard themselves. For example, to prevent the spread of the virus, individuals may heed advice from their partners and maintain social distancing.

Cultural differences also influence responses to pandemics. Asian cultures, which emphasize social responsibility and collectivism, often encourage individuals to follow societal norms and suppress personal desires. In contrast, Western cultures place a greater emphasis on autonomy, independence, and self-regulation.

H3: Pandemics have a positive impact on subjective norms.

Perceived behavioral control refers to an individual’s assessment of how easy or difficult it is to perform a particular behavior. People are more likely to exert effort to carry out an action if they believe they have the resources and skills needed and expect fewer obstacles. The Covid-19 pandemic disrupted global supply chains and created a workforce crisis, limiting consumer access to sustainable products and services. This led to a surge in stockpiling, although supply capacity could not keep up with demand.

Consumers must also factor in the added costs of green products, which have risen due to market fluctuations caused by the pandemic's direct and indirect effects, along with income loss from job cuts and social distancing mandates. However, reduced spending provides an opportunity to promote sustainable consumption patterns. These include lowering energy use, increasing recycling, cooking at home more often, avoiding unnecessary purchases, and buying secondhand clothing to manage living costs.

H4: Pandemics promote sustainable consumption behavior by encouraging cost-saving and eco-friendly practices.

IV. Discussion

Green consumption has emerged as a popular and novel approach to consumption and lifestyle, gaining traction among a large number of consumers. This approach emphasizes environmental impact, resource efficiency, and consumer rights. Rooted in health protection and resource conservation, green consumption aligns with both personal well-being and environmental sustainability, with its core principle being sustainable consumption. According to the China Consumers' Association, green consumption encompasses three key elements: (1) encouraging consumers to choose eco-friendly products, (2) focusing on responsible waste disposal to prevent environmental pollution, and (3) promoting a shift in consumer attitudes towards valuing nature and prioritizing health. This approach aims to balance the pursuit of a comfortable life with the conservation of resources and energy, ultimately achieving sustainable consumption.

The concept of green consumption was first introduced in 1987 by British scholars Elkington and Hailes in their book *Green Consumer's Guide*. They defined green consumption as the avoidance of certain products, including: (1) goods harmful to health, (2) products that use excessive resources during their lifecycle, (3) items with unnecessary packaging or short lifespans, (4) products derived from endangered animals or natural resources, (5) items involving cruelty to animals, and (6) goods that negatively impact other countries, particularly developing nations (Lin & Xu, 2000; Xu, 2007).

Today, the "5R" principle of green consumption is globally recognized (fig.1): (1) save resources, (2) reduce pollution, (3) reuse and buy durable products, (4) recycle through proper waste sorting, and (5) protect and preserve nature (Wang, 2006). This broad concept covers not only consumer behavior but also the mindset and values behind consumption. Drawing from psychological theory, green consumption is characterized by three interconnected components: green consumption cognition (awareness and knowledge about green practices), green consumption attitude (a favorable or unfavorable psychological stance towards green consumption), and green consumption behavior (specific actions such as buying energy-saving products or avoiding disposable items). According to behavioral science, cognition influences attitudes, which in turn shape behaviors, creating a tightly linked cycle that forms the concept of green consumption.

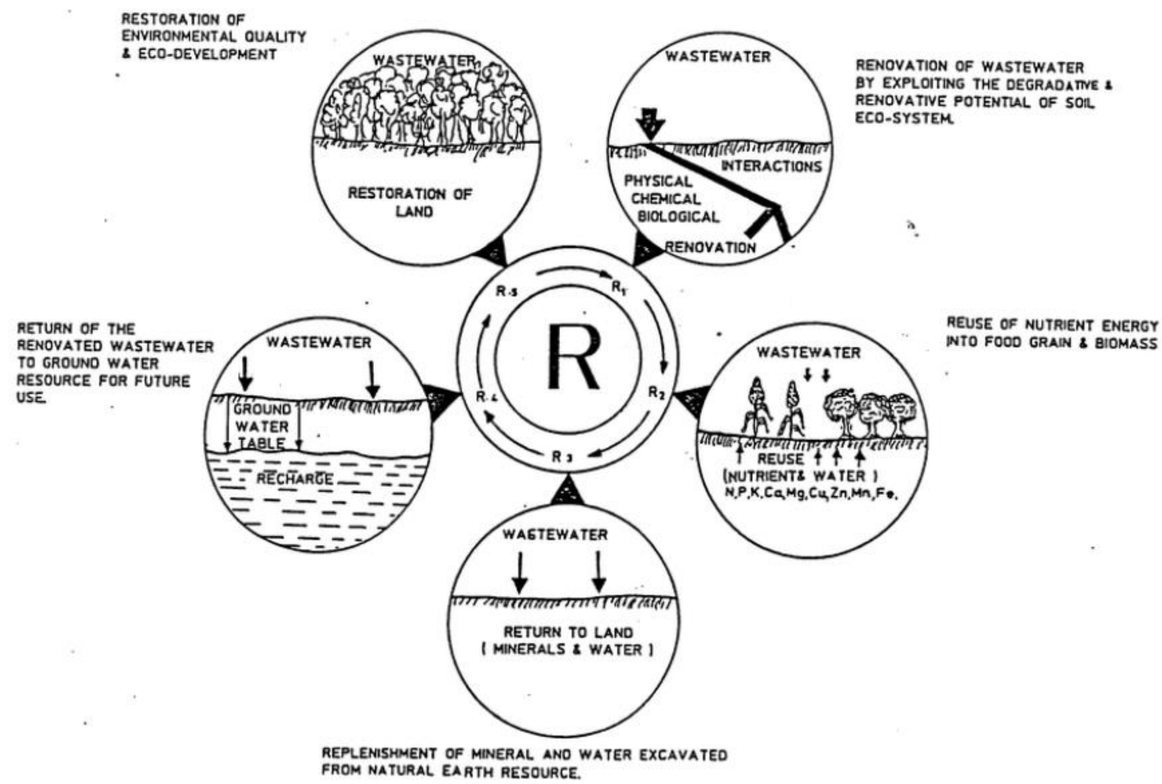

Figure 1: *5R concept of wastewater management and recycling, reuse and eco-development*

Furthermore, Si (2002) identified four core aspects of green consumption: (1) minimizing resource and energy usage (economic consumption), (2) reducing waste and pollutants (clean consumption), (3) ensuring that consumption does not harm health (safe consumption), and (4) avoiding consumption patterns that jeopardize future generations (sustainable consumption). Pan (2003a) proposed a hierarchy of green consumption, starting with moderate consumption, followed by the use of green products, then spiritual consumption, and ultimately leading to a simpler and easier lifestyle. Green consumption not only fosters sustainable development but also helps harmonize the relationship between humans and nature, promoting health, equity, and the long-term prosperity of human society.

Raukoff and Wu (2013) define green consumption behavior as the actions of consumers who aim to protect the environment and minimize the negative impacts of consumption throughout the entire lifecycle of a product—from purchase to use and post-use disposal. Similarly, Chen et al. (2013) describe green consumption as a responsible and sustainable mode of consumption, in which consumers, after recognizing environmental issues, seek to fulfill their purchasing needs while minimizing environmental harm. In reviewing the literature, the terminology for green consumption behavior varies, with some scholars using terms like "ecological consumption" and others using "green consumption." However, after analysis, these terms are found to be fundamentally consistent. This paper uses the term "green consumption behavior," although other sources may refer to it as "green purchasing behavior," with no essential difference between the two.

The prevailing definition of green consumption highlights rational consumption where individuals not only focus on their own health and interests but also emphasize environmental protection, reducing resource waste, preventing pollution, and fulfilling social responsibilities. Other researchers frame green consumption as a socially responsible behavior where consumers are aware of the broader consequences of their consumption choices.

Green consumption is also considered an environmental behavior. Scholars have studied the factors influencing environmental behaviors, offering valuable insights into green consumption research. Stern (2000) categorized environmental behaviors into four types: (1) activism, (2) public-level environmental behaviors (such as supporting environmental policies or paying higher taxes for environmental protection), (3) individual-level environmental behaviors (such as green consumption), and (4) environmental behaviors of organizations. Green consumption falls under individual-level environmental behaviors, setting it apart from other types.

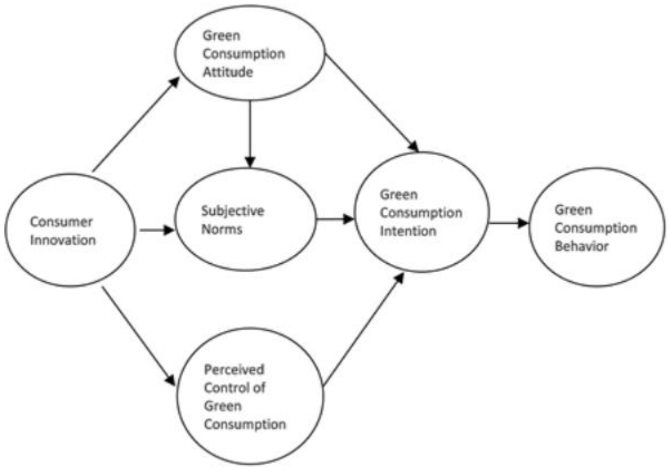

Figure 2: *The influence of consumer innovation on green consumption behavior*

Green consumption differs from other environmental behaviors in a few key ways. First, it is directly tied to consumer choices, where people consider factors like cost, quality, and environmental impact in their purchasing decisions. Second, consumers may use green products and brands as a way to express their values and identity. These distinctions between green consumption and other environmental behaviors suggest that different factors may influence green consumption compared to other types of environmental actions.

Abstract

The article presents a study that attempts to investigate the features of students' environmental behavior. The peculiarity of this work is the inclusion of some indicators of the digital footprint of individuality (openness/closedness) of the profile and the color scheme of the profile) in the analysis of the results obtained using valid methods characterizing students' attitudes to environmental issues. The authors trace the relationship between the indicators characterizing environmental behavior and the studied indicators of the digital footprint of students' individuality. Also, in the process of analyzing the results obtained, a relationship was revealed between the age characteristics of students and the features of their profile in VK.

Keywords: digital trace of individuality, integral individuality, environmental issues, digital environment, VK users, environmental behavior, student age

I. Introduction

Trying to analyze the digital trace of individuality, or as we propose from the point of view of the theory of integral individuality of V.S. Merlin and the theory of polymorphic individuality of V.V. Belous [1] - the supra-status (digital) level of individuality, it is necessary to evaluate its profile in the social network according to available open parameters. In this study, we attempted to analyze the characteristics of the attitude to environmental issues in the student environment, on the one hand, and, on the other hand, to link these characteristics with some parameters of the digital trace of individuality - the openness or closedness of the profile in the social network and the predominant colors in the photographs that are available in the profile. This approach is relevant, since the actively developing digital environment makes its own adjustments to the structure of individuality [2]. Not so long ago - in the early 2000s, psychologists considered this environment, the environment of the Internet space exclusively as a resource that negatively affects the psyche. In studies, the Internet environment was considered addictive.

II. Methods

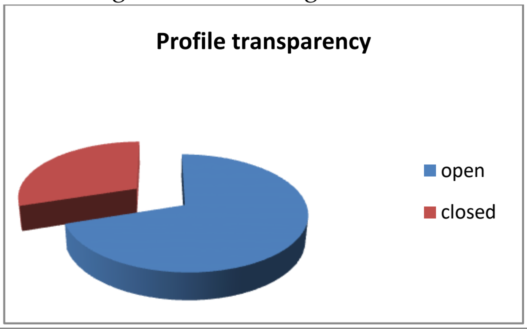
The study involved first-year students of the Institute of International Relations of the Federal State Budgetary Educational Institution of Higher Education "Pyatigorsk State University" - future journalists and specialists in international relations. The diagnostics were conducted in September 2024. We asked the subjects to provide a link to their profile on the social network during the diagnostic methods. Of the 123 students who passed the test, 98 provided this information. Another feature of this component of the study was that several students provided incorrect access to the profile. Thus, 86 people remained in the sample - 69 girls and 17 boys. The profile for analysis was characterized by 2 indicators - openness / closeness of the profile and the predominant color of photos, pictures, etc., which are available in the profile.

To diagnose attitudes towards environmental issues and manifestations of environmental behavior, we used valid diagnostic methods – the Method of Diagnosing Motivation for Interaction with Nature "Alternative"; the Scale of Environmental Concern and the Method of "Differential Emotions Scale" [3]. To process the obtained data, we used statistical data analysis.

At the final stage of the study, a comparative analysis of the obtained data and their interpretation was carried out.

III. Results

At the first stage, our goal was to characterize students' profiles on VK by two characteristics: openness or closedness of the profile and the predominant color scheme of the profile photo, which will indicate the emotional background of the digital trace of individuality.



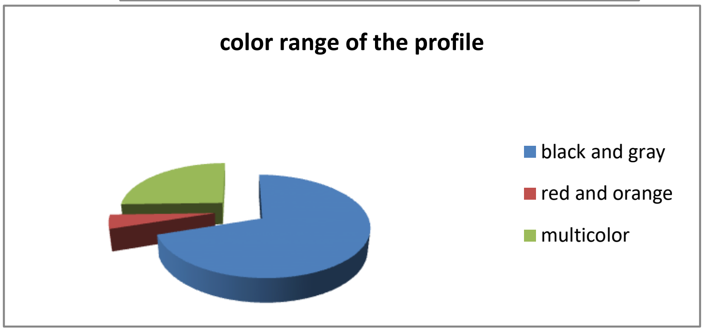


Figure 1: *Results of the analysis of profile openness/closedness and profile color scheme" (%)*

Of the provided VK profiles, 30% were closed. The remaining 70% are open and filled profiles. We assume that students exhibit extroverted behavior in the digital space - they are open to the digital environment and ready to interact. As for the color scheme, black or gray predominates in most profiles (77%). Red or orange predominates in 5% of cases, and in 28% of cases, there is a variety of colors and no dominance of any color. The predominance of black indicates an emotional state characteristic of the stage of adaptation to the university conditions, the presence of a certain stress characteristic of the transition from adolescence to young adulthood. Black in this situation is a desire for independence, resistance to external pressure and denial of any authorities. To this characteristic should be added the manifestation of aggression and depression.

In the further analysis, we will consider the results of diagnostics using methods that determine environmentally responsible behavior - the Method of Diagnostics of Motivation for Interaction with Nature "Alternative"; the Scale of Environmental Concern and the Method "Scale of Differential Emotions". In the analysis, we will trace the relationship between the obtained results and the features of the digital trace of individuality.

Fig. 2 shows the results of diagnostics using the Alternative method of diagnosing motivation for interaction with nature. In the sample under study, two types of motivation predominate: aesthetic and cognitive. This fact indicates that respondents perceive nature as an object of beauty when actively interacting with it. High rates of this type of motivation are demonstrated by 68% of students with an open VK profile.

Also, high rates are presented in the cognitive type of motivation, which indicates the attitude to the environment as an object of knowledge in interaction with it. This type of motivation prevails in 30% of students with an open profile. It should be noted that 89% of students have a multi-color profile photo.

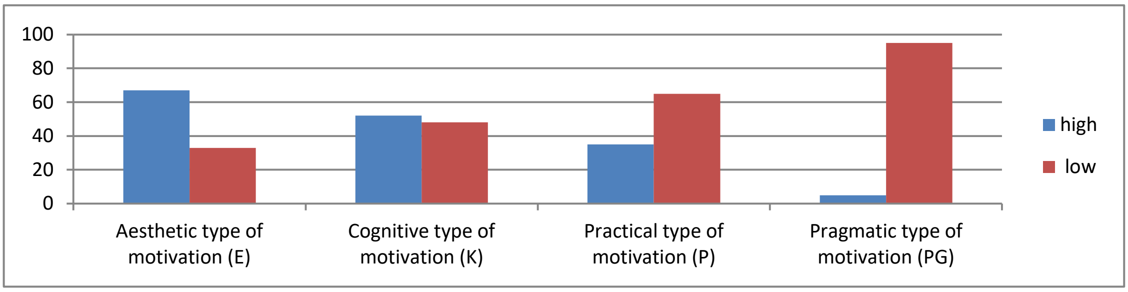

Figure 2: *Results of the Methodology for diagnosing motivation for interaction with nature "Alternative" (%)*

Fig. 3 shows the results of the "Scale of Environmental Concern" method. It is obvious that high scores were obtained for all scales, which indicates concern about the fate of animals, birds and the ecosystem as a whole, as well as concern about the impact of the consequences of environmental problems on children, people who live in the same region. A high level is also observed for the "Egoistic Concern" indicator - everything that concerns the consequences of environmental problems for one's own health, one's own lifestyle and future. Such scores indicate a high level of involvement in understanding the consequences of environmental problems in real life. Moreover, such data are shown by all representatives of this sample - students with open and closed profiles and with all types of color schemes in the profile.

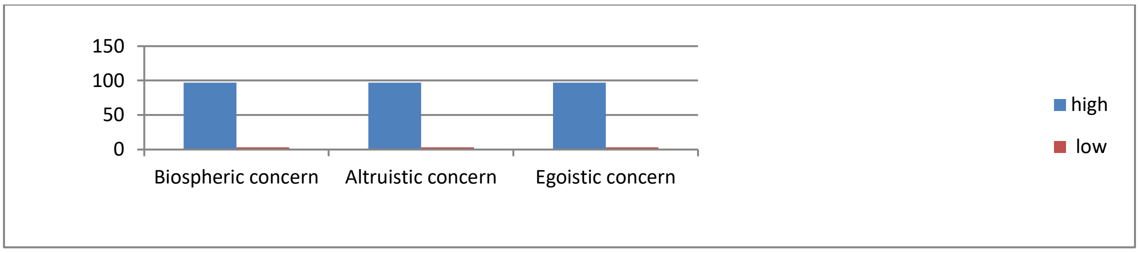

Figure 3: *Results for the Environmental Concern Scale Methodology (%)*

Based on the data obtained, we can state a high level of environmentally responsible behavior.

The results presented in Fig. 4 determine the level of emotion that the subjects showed regarding the current situation. In the block of positive emotions, there is a predominance of low emotion in all indicators: "Interest", "Joy" and "Surprise". Comparing the data with the manifestation of the digital trace of individuality, and specifically in the prevailing color scheme - black and gray, there is a connection between the emotional state and the prevailing color of the profile. In the block of negative emotions, low values are recorded for all four indicators, which once again confirms the closeness and some emotional instability inherent in first-year students. In general, the general index of positive emotions and negative emotions are distributed approximately in equal shares between high and low indicators. At the same time, the picture is complemented by the predominance of the low level of the indicator " Anxious and depressive emotions ", which characterizes the predominance of environmental features over individual ones in the manifestation of emotions regarding the situation associated with the attitude to environmental problems.

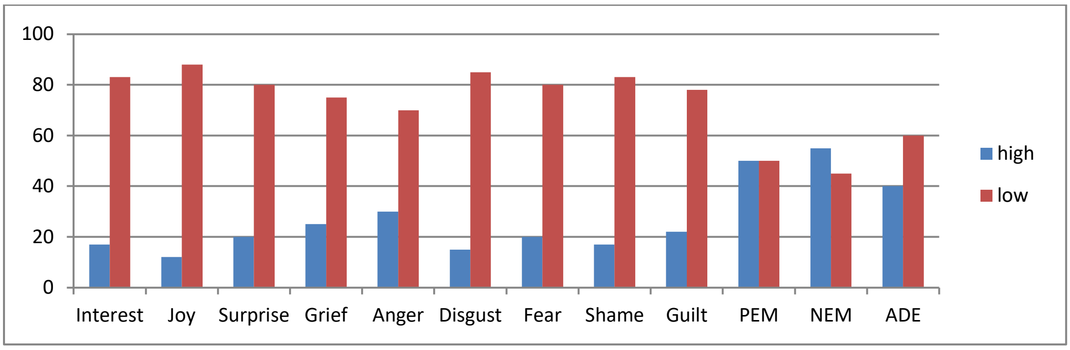

Figure 4: *Results for the "Differential Emotions Scale" method (%)*

IV. Discussion

The study by Ivanova I.V. and Konenkova N.V. examines the influence of the reflexive-value approach on the formation of environmentally responsible behavior of young people [4]. Scientists have proven the importance of interpersonal relationships and both general and environmental culture in the formation of environmentally responsible behavior. The study by Matovaya N.I and Shagarova L.M. highlights a very relevant and burning topic of our country's share - tourism and its development [5]. Their work examines the need for environmentally responsible behavior of tourists in nature conservation areas. This problem is considered within the framework of the contradiction between the need to develop domestic tourism and the need to preserve unique natural monuments of Russia. Demenshin V.N. in his "Review of Foreign Studies of Environmental Consciousness" [6] refers to the studies of I. Tilikidou and J. Zotos, who, based on the works of B. Schlegelmilch, developed an approach to describing environmental consciousness, in which they included all components of environmentally responsible consumer behavior, while the behavioral aspect includes pro-environmental purchasing behavior, pro-environmental behavior after purchase and environmental protection activities [7]. Summarizing the sources we have cited, we can state that environmentally responsible behavior in the student environment is not considered in psychological science.

In the aspect of the digital trace of individuality, Tulupyeva T.D. and Ivanova A.Yu. consider a psychological approach, which involves studying the manifestation of mental properties and characteristics of a person during communication and behavior on the network, taking into account that communication occurs within social groups, this approach is characterized as socio-psychological [8; 9; 10]. Gaidash O.V. in his study, describing modern approaches to the interpretation of the digital trace, states the fact that the features of these characteristics of individuality are used mainly by marketers [11].

From the point of view of the theory of integral individuality by V.S. Merlin and polymorphic individuality by V.V. Belous [12], the digital trace of individuality (the data that can be openly available in the digital environment) has not yet been considered as a supra-status level of integral individuality. In this paper, we postulate a new approach to the study of the holistic individuality of a modern person.

Abstract

The COVID-19 pandemic has been an important catalyst for the adoption of sustainable environmental practices. Restrictive measures such as quarantines and curtailment of international travel have reduced greenhouse gas emissions and improved air quality in cities. This has provided an opportunity to rethink consumption and resource use patterns and accelerate the transition to greener and more sustainable approaches across sectors including transport, energy and manufacturing. The pandemic has also highlighted the relationship between environmental health and human quality of life, spurring the development of green economy, renewable energy and circular economy initiatives. In the long term, the adoption of sustainable practices can not only mitigate the impact of climate change but also improve public health and well-being. COVID-19 pandemic, sustainable environmental practices, climate change, air quality, renewable energy, circular economy, quality of life, green economy.

Keywords: sustainable environmental practices, climate change, air quality, renewable energy, circular economy, quality of life, green economy

I. Introduction

The COVID-19 pandemic triggered extensive global measures aimed at curbing its spread, resulting in unexpected consequences for both the environment and the economy. These unforeseen effects have shed new light on how pandemic control strategies influence environmental health and economic systems, thereby affecting global sustainability efforts. This detailed narrative review thoroughly explores the complex relationship between COVID-19 control measures and environmental well-being (fig.1). Our study examines critical ecological factors such as air and water quality, noise pollution, soil quality, and energy consumption, analyzing how these aspects changed during lockdown periods. We also investigate the pandemic's unexpected economic implications, especially the rapid shift toward digitization and e-commerce. Our research methodology relies on a comprehensive literature review, utilizing meticulous comparisons between conditions during lockdown and those prior to it. Our results indicate a significant improvement in environmental quality indicators during peak lockdown phases, exceeding pre-pandemic levels. This change highlights the possibility of integrating sustainable behaviors into everyday life. The pandemic has acted as both an awakening and a catalyst for sustainable practices. This review emphasizes the unprecedented positive environmental and economic insights revealed by the COVID-19 crisis. As the global community prepares to enhance health and economic resilience for future challenges, the critical lessons learned from the pandemic's benefits should inform the development of future environmental policies and goals. This interplay among health, economy, and environment offers a unique chance to move closer to our collective sustainable development objectives. The COVID-19 outbreak in 2020 prompted the World Health Organization (WHO) to declare a global public health emergency. As of May 2023, COVID-19 had resulted in over 750 million cases and nearly 7 million deaths worldwide. In response to the virus's severity and rapid spread, governments implemented various measures such as lockdowns, restrictions on social interaction, and limitations on movement and economic activities. Among the most affected sectors were transportation, with air travel plummeting by 96%, and the industrial sector, as global oil consumption and prices dropped sharply.

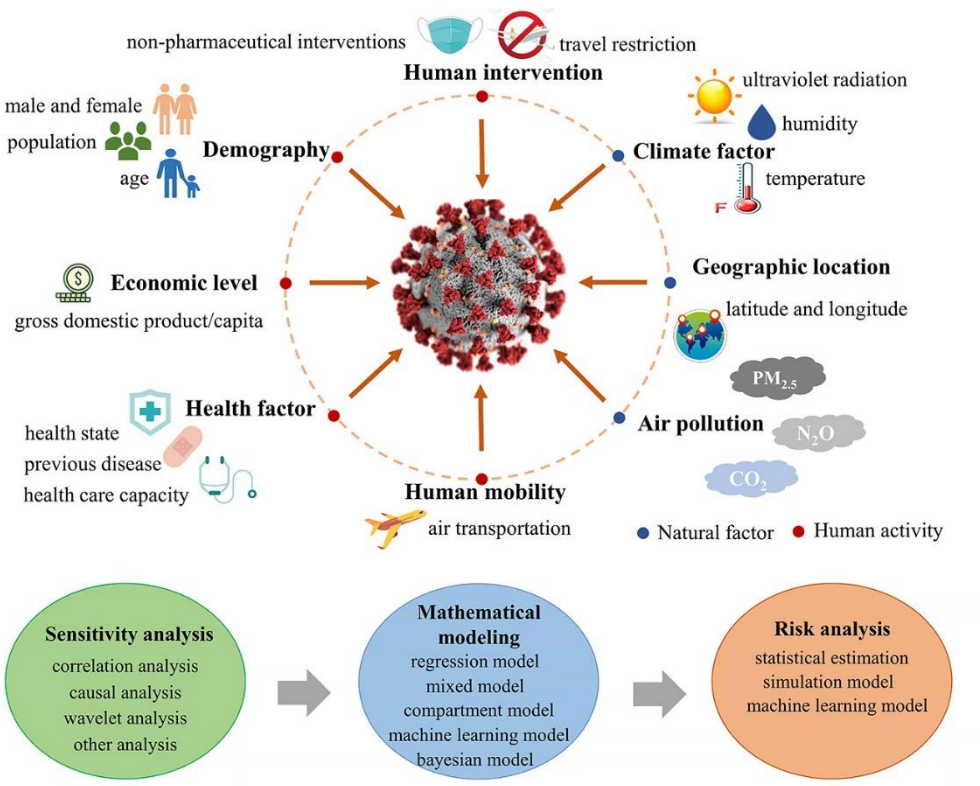

Figure 1: *Impact of main geo-environmental factors on global COVID-19 spread.*

Inger Andersen, Executive Director of the United Nations Environment Program, suggested that post-pandemic leadership in environmental sustainability would be crucial. While the pandemic shifted the global focus toward public health over environmental conservation, it also led to several positive environmental developments. For instance, reduced economic activity lowered pollution and industrial waste emissions, and ecosystems began to recover. Lockdowns helped mitigate environmental issues like climate change, ozone depletion, and air pollution. Silva et al. (2021) noted that COVID-19 indirectly supported several UN Sustainable Development Goals (SDGs) by reducing greenhouse gas emissions, air and noise pollution, and pressures on wildlife.

However, negative environmental impacts also emerged, such as the increased use of single-use plastics and worsening indoor air quality. The pandemic highlighted the intricate relationship between human health, economic stability, and environmental health. Drawing insights from this complex interplay is essential for fostering sustainable practices in the post-pandemic era.

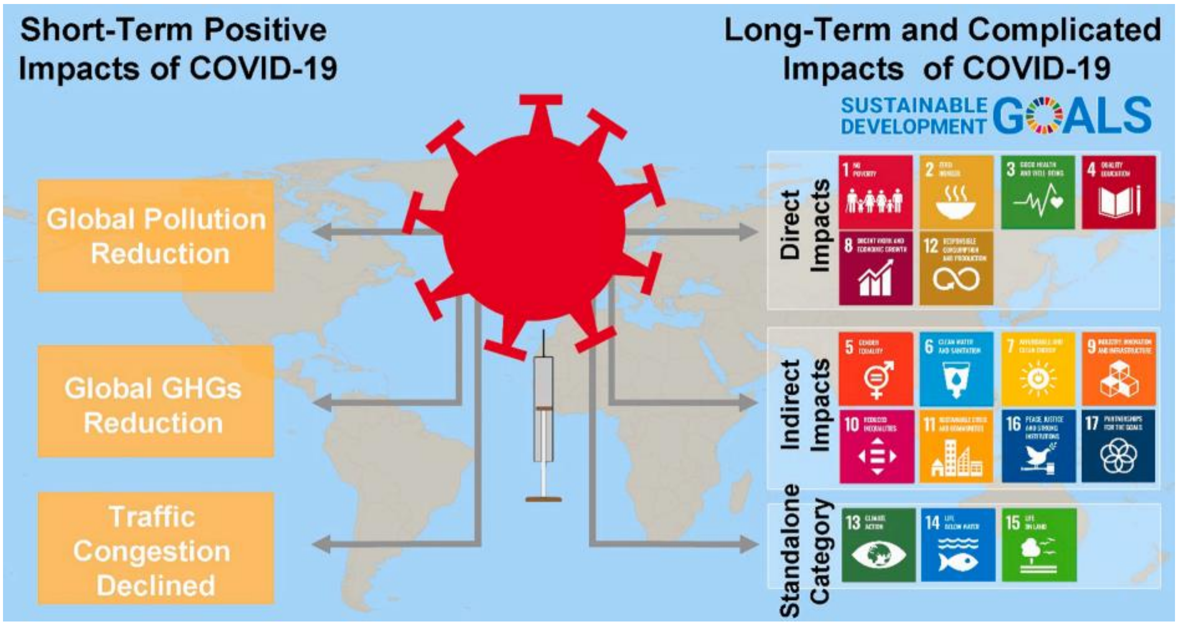

Figure 2: *Conceptualized diagram showing the 17 SDGs as impacted by the COVID-19 in three categories. SDGs-icons are reproduced from UN-website (UN-SDGs)*

This study aims to thoroughly examine both the positive and negative environmental consequences of the pandemic. It will assess immediate impacts, such as improvements in air and water quality, and explore how these changes align with specific SDGs. By linking these environmental shifts to broader global sustainability goals, the study underscores the need for interdisciplinary collaboration in addressing future sustainability challenges. It also calls for further research into the long-term environmental implications of the pandemic, advocating for the continued adoption of eco-friendly practices like digitization and reduced industrial activity. The study's hypotheses propose that COVID-19 lockdowns led to significant improvements in air and water quality, that these improvements contribute to the achievement of certain SDGs, and that the pandemic has revealed sustainable practices that could have lasting positive environmental impacts.

II. Methods

A comprehensive literature review was conducted to gather relevant scientific articles, governmental reports, and research studies examining the impact of COVID-19 on air, water, and soil pollution. Key databases such as PubMed, Google Scholar, and government websites were searched using keywords like "COVID-19," "air pollution," "water pollution," "soil pollution," "lockdown," and "pandemic." The search was restricted to publications from the past five years (2018–2022) to ensure the inclusion of recent and pertinent data.

To ensure rigor, specific inclusion criteria were set, focusing on studies published between 2018 and 2022 that addressed COVID-19's effects on air, water, or soil pollution. These studies needed to provide quantitative data on pollution indicators such as pollutant concentrations, emission levels, or water quality metrics, and compare pre-pandemic levels to those during the lockdown period. Only peer-reviewed articles, governmental reports, and reputable studies were considered. Exclusion criteria eliminated studies published before 2018, those lacking direct relevance to pollution impacts of COVID-19, non-quantitative studies, and non-peer-reviewed materials like opinion pieces and editorials.

The data synthesis and analysis process involved extracting key data from the selected studies, focusing on changes in pollution indicators. This data was categorized by pollution type (air, water, or soil) and geographic region for structured analysis. Summary tables were compiled to compare data across studies, emphasizing significant trends. Descriptive statistical methods were employed to quantify changes in pollution levels during lockdowns relative to pre-pandemic baselines, while comparative analysis helped identify consistent trends across regions and pollution types. The results were also linked to specific United Nations Sustainable Development Goals (SDGs) to assess the broader sustainability implications.

Despite the thorough approach, the study had several limitations. It relied on existing data, which varied in measurement techniques, monitoring locations, and reporting formats, potentially affecting the comparability of findings. Additionally, the study primarily focused on short-term effects of the pandemic, with the acknowledgment that further research is needed to understand long-term impacts. Nevertheless, these methodological details enhance the transparency and reproducibility of the review, offering a solid foundation for evaluating the environmental consequences of COVID-19 lockdowns.

III. Results

The COVID-19 lockdown led to a significant reduction in industrial activities and a subsequent drop in air pollution from sources such as automobiles, power plants, and industrial sites across many urban areas worldwide. This improvement in air quality was confirmed by pollution-monitoring satellites from NASA and the European Space Agency, which reported sharp declines in air pollution, particularly in China and European cities. For example, air pollution in China dropped by 20–30%, and India experienced its lowest airborne particle concentrations in 20 years. Major European cities like Rome, Milan, Madrid, and Paris saw reductions in air pollution by up to 54%, while levels of nitrogen dioxide (NO2) in Eastern and Central China decreased by 10–30%. Similarly, the United States and the UK also recorded notable reductions in NO2 levels.

These findings are consistent with previous research linking industrialization and urbanization to environmental degradation. However, while the improvements in air quality during the lockdown were substantial, they are not enough to achieve the Paris Agreement's goal of limiting global warming to below 1.5°C. Air pollution, exacerbated by industrial and transportation emissions, poses a serious risk to human health, contributing to tens of thousands of premature deaths annually in the UK alone. Long-term exposure to air pollution has been linked to respiratory illnesses, heart disease, lung cancer, and asthma, all of which have been worsened by COVID-19. Yet, during the lockdown, improved air quality likely saved lives by reducing the harmful effects of pollution.

Despite these positive outcomes, scientists caution that the temporary reduction in pollution during the pandemic is not a permanent solution to the broader climate and health challenges posed by air pollution.

IV. Discussion

The COVID-19 pandemic led to the largest annual decline in CO2 emissions ever recorded, exceeding reductions observed during any prior economic crisis or wartime period (Verma and Prakash, 2020). This unprecedented drop in global CO2 emissions was one of the major environmental benefits of the pandemic, primarily driven by a sharp decline in energy consumption, which in turn reduced greenhouse gas (GHG) emissions worldwide (see fig. 3). The decrease is primarily attributed to the ground transportation sector (−18.6%), as well as domestic (−35.8%) and international aviation (−52.4%) (Figs. 3). Figure 3 illustrates the distribution of daily emissions changes across different sectors. The largest contributors to the global emissions reduction in 2020 were ground transportation (−613.3 Mt CO2, 40% of the total decrease; purple in Fig. 3a) and the power sector (−341.4 Mt CO2, 22% of the total decrease; orange in Fig. 3a), with smaller reductions in the industrial sector (−263.5 Mt CO2, 17% of the total decrease; warm orange in Fig. 3a) and the aviation sector (including both domestic and international aviation, −200.8 Mt CO2, 13% of the total decrease; yellow in Fig. 3a). Relatively minor decreases were seen in international shipping (−89.1 Mt CO2, 6% of the total decrease; blue in Fig. 2a) and emissions from the residential sector, which includes residential, public, and commercial buildings (−42.5 Mt CO2, 3% of the total decrease; green in Fig. 2a). The reduction in CO2 emissions during the pandemic was even greater than the combined decreases seen in the five previous economic recessions (IEA, 2020).

However, as economies recover, emissions tend to rise again, potentially masking the progress made during the pandemic unless there is a focused shift towards cleaner, more sustainable energy infrastructures (IEA, 2020). At the same time, some cities saw an increase in pollutants like sulfur dioxide (SO2) and carbon monoxide (CO), which is likely due to a rise in private vehicle use during the pandemic as people avoided public transport and carpooling (Orak and Ozdemir, 2021). These pollutants, which primarily come from the combustion of fossil fuels such as coal and oil, remained prevalent in areas heavily reliant on non-renewable energy sources, such as coal-fired power plants (Filonchyk et al., 2020).

In colder months, the increased demand for heating in residential areas, particularly those dependent on fossil fuels, is expected to further elevate emissions, counteracting some of the temporary reductions achieved during the lockdown. This underscores the need for a transition to cleaner energy sources to sustain the environmental benefits observed during the pandemic. The COVID-19 lockdown brought significant improvements in air quality, primarily due to reduced industrial activities and fewer vehicles on the road. However, maintaining these improvements requires a strategic and gradual shift towards cleaner energy and transportation systems. A key step is increasing the number of electric vehicle (EV) charging stations and encouraging the use of low-emission fuels. Cities need to reorganize by introducing measures like clean air zones or low-emission classifications to restrict polluting vehicles from entering congested urban areas (PHE, 2020).

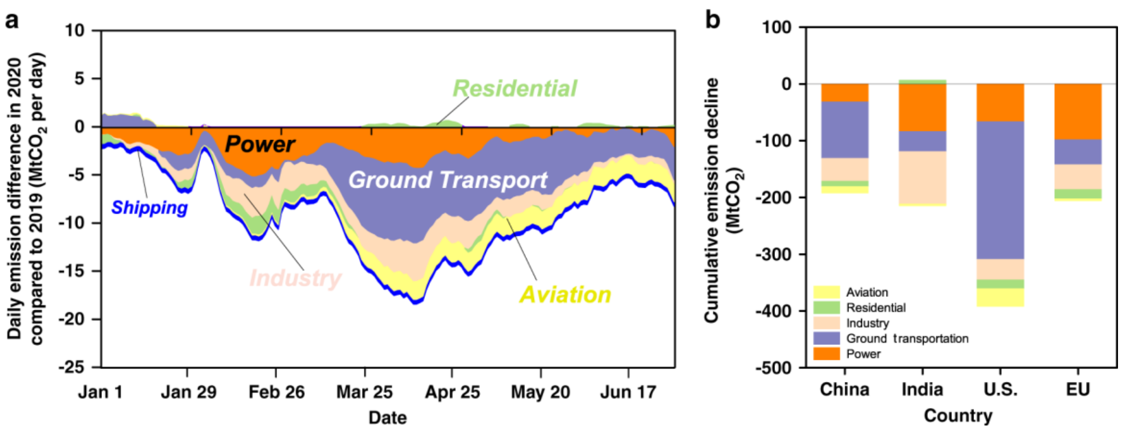

Figure 3: *Sectoral effects of COVID-19 on CO2 emissions*

A critical component of decarbonizing road transport and integrating renewable energy into power grids is the advancement of battery technology (World Economic Forum, 2019).

Overcoming these challenges will require a circular value chain that includes designing products for extended life, implementing Vehicle-to-Grid (V2G) systems, and scaling up shared electric mobility solutions. Integrating the transportation and energy sectors is crucial for building a sustainable battery ecosystem (Masiero et al., 2017; PHE, 2020). Yet, simply replacing all vehicles with electric models won't solve traffic congestion or resource consumption issues. Instead, adopting circular value chains can help minimize these risks, enabling the development of a more sustainable battery industry by reducing emissions during production, ensuring ethical working conditions, and promoting reuse, recycling, and remanufacturing.

The assumption that industrialized economies inherently produce substantial pollution is essential, as air pollutants significantly impact COVID-19 death rates (Fofana et al., 2020). Studies have demonstrated that higher levels of air pollution contribute to increased fatalities. For example, Wu et al. (2020) found that a 1 $\mu g/m^3$ increase in fine particulate matter (PM2.5) correlated with a 15% rise in COVID-19 mortality. These findings highlight the urgent need to prioritize air quality improvements, as poor air quality can exacerbate the spread and severity of airborne diseases like COVID-19. For instance, strong airflow in an air-conditioned restaurant in Guangzhou, China, facilitated viral transmission among diners (Liu et al., 2020).

Road traffic noise, a significant environmental issue in Europe, affects millions of people's health and well-being, contributing to a range of negative outcomes such as sleep disruption, anger, and serious impacts on metabolic and cardiovascular systems (EEA, 2020). The European Environment Agency (EEA) reported that approximately 20% of Europeans live in areas with noise levels that are harmful to their health. This chronic noise pollution leads to around 12,000 premature deaths and 48,000 new cases of ischemic heart disease annually. Additionally, about 22 million people experience chronic high irritability due to noise, and 6.5 million suffer from severe sleep disturbances (EEA, 2020).

Airplane noise has also been shown to impair cognitive abilities, particularly reading, in children. For example, one estimate suggests that airplane noise negatively impacts the reading abilities of 12,500 schoolchildren. While air pollution leads to more premature deaths, noise pollution has a broader impact on people's quality of life and mental health (EEA, 2020).

The COVID-19 pandemic, however, brought a drastic reduction in noise pollution due to a sharp decline in road traffic and industrial operations. Lockdowns reduced noise input into both the troposphere and stratosphere, as noted by Verma and Prakash (2020). Road traffic became rare during this period, contributing to an unprecedented quietness in urban environments (Nazir et al., 2021). This reduction in environmental noise created a conducive environment for outdoor activities, including exercise. A global study found that, during the lockdown, exercise rates increased dramatically. Average individuals experienced an 88% increase in their exercise rates, moderately active individuals saw a 38% rise, and sedentary individuals had a 156% increase (Snider-McGrath, 2020). These statistics reflect the broader positive influence of reduced noise and air pollution on physical well-being.

Marine life also benefited from the reduction in human activity during the lockdown. Noise pollution in the ocean, largely caused by shipping and seismic air cannon experiments for gas and oil exploration, can severely disrupt marine life. Sound travels much farther and faster in water than in air, making noise a significant threat to marine ecosystems (Duarte et al., 2021). One study on humpback whales and other marine animals found that elevated stress hormone levels in these species were linked to increased ocean noise, and prolonged stress can negatively impact reproductive success (Rolland et al., 2012). The temporary reduction in marine traffic during the pandemic likely provided some relief to marine life, although the long-term consequences of decreased ocean noise remain to be fully understood.

In summary, the COVID-19 lockdown led to significant reductions in both terrestrial and marine noise pollution, highlighting the deep connection between human activities and environmental health. The data underscores the importance of addressing noise pollution not only for human well-being but also for the broader ecological health of both land and marine environments.

A NEW DESİGN SOLİD GRAVİTY ENERGY STORAGE SYSTEM FOR RENEWABLE ENERGY

Nijat Mazhlumov, Vusal Jivishov
•
Azerbaijan Technical University
mecnunovnicat63@aztu.edu.az
ejivishov@yahoo.com

Abstract

Climate change and global warming necessitate a shift towards renewable energy as the primary source of power. Consequently, environmentally clean renewable energy technologies are rapidly developing. However, the intermittent nature of renewable energy sources has introduced new challenges in grid integration. Addressing these issues is crucial for solving environmental problems on a large scale. To mitigate these emerging challenges, the demand for energy storage systems has increased significantly. These systems play a vital role in maintaining grid stability during the utilization of renewable energy sources and preventing energy crises. By connecting to energy networks, they store excess generated energy and return it to the grid when necessary, ensuring stable system operation. In recent years, solid gravity energy storage technologies have emerged as a promising solution among energy storage systems. This article presents a novel design for a solid gravity energy storage device. The primary objectives of this system are to facilitate large-scale grid integration of renewable energy sources and maintain system stability. Solid gravity energy storage technology offers several advantages over other energy storage technologies, including cost-effectiveness, high security, long lifespan, and increased flexibility. The development and implementation of these systems play a crucial role in advancing the energy sector and supporting the transition to renewable energy sources.

Keywords: mechanical energy storage, renewable energy, solid gravity energy storage, sustainable energy

I. Introduction

The global population growth and rapid industrial development are driving an increasing demand for energy. Both developed and developing countries are prioritizing the energy sector due to its irreplaceable role in economic growth and national development. This escalating energy demand is primarily met through two types of sources: renewable and non-renewable.

Currently, fossil fuels (oil, gas, and coal) account for the majority of global energy consumption [1,2]. Their widespread use is primarily attributed to their relatively low cost and accessibility [3]. However, despite their economic efficiency, fossil fuels are the main contributors to climate change and global warming, posing urgent challenges for all nations [4].

The environmental impact of fossil fuels is severe and long-lasting. Their combustion releases significant amounts of greenhouse gases and carbon dioxide into the atmosphere [1,3]. These emissions are the primary drivers of climate change and global warming, with fossil fuels responsible for over 75% of global greenhouse gas emissions and 90% of all carbon dioxide emissions [5].

Climate change and global warming have far-reaching consequences, affecting human health, water resources, and food security [4]. They contribute to droughts, vegetation destruction, heat waves, and increased water vapor in the atmosphere [4,6].

According to the Intergovernmental Panel on Climate Change (IPCC), the Earth's average temperature has risen by approximately 0.8°C over the past century [7]. Without significant reductions in greenhouse gas and carbon dioxide emissions, global warming is projected to exceed 1.5°C and potentially reach 2°C in the 21st century. The Paris Agreement stipulates that to mitigate these problems, greenhouse gas and carbon dioxide emissions should be reduced by 50% by 2030 and reach "net zero" by 2050 [6,8].

Renewable energy sources offer a clean and sustainable alternative to fossil fuels. Unlike their non-renewable counterparts, renewable energies produce negligible greenhouse gas emissions and have minimal negative impact on the environment and human health. These sources are inexhaustible and have the potential to meet global energy needs many times over [1,8,9,10]. The main types of renewable energy sources include:

- Solar energy
- Wind energy
- Hydroelectric energy
- Geothermal energy
- Wave energy
- Bioenergy

Renewable energies contribute significantly to reducing energy dependence and promoting economic and social development. Their availability in all countries and zero fuel costs make them an attractive option for many nations [1]. As a result, global investment in renewable energy continues to increase annually. According to the International Energy Agency, renewable energy capacity is expected to increase by 50% in 2023 compared to the previous year, reaching 507 GW. Solar, wind, and hydroelectric power are currently the most widely adopted renewable technologies [11].

Despite their numerous advantages, renewable energy sources face several [12]:

1. High initial costs: Development and installation of renewable energy technologies require substantial upfront investments [12].
2. Geographical constraints: Large open areas are often needed for wind and solar energy production, limiting suitable locations [12].
3. Production variability: Solar and wind energy depend on weather conditions, leading to inconsistent energy generation [12].
4. Energy storage: The intermittent nature of many renewable sources necessitates efficient energy storage systems [12].
5. Supply constraints: Equipment, materials, and raw materials for energy production can create bottlenecks [12].

Addressing these challenges is crucial for the widespread adoption of renewable energy and the complete phaseout of fossil fuels. Energy storage technologies play a vital role in overcoming the intermittency of renewable sources, allowing excess energy to be stored and used when needed. The development of these technologies is one of the most effective ways to combat climate change and global warming [13,14].

II. Classification and Advancements in Energy Storage Technologies

Energy storage technologies play a crucial role in the energy sector, facilitating the transition to renewable energy sources as the primary power supply and ensuring grid stability. For renewable energy to become the dominant source, these technologies must address the inherent intermittency of renewables. Energy storage systems are considered the most effective solution for achieving this stability [13,14,15,16].

These systems integrate with renewable energy networks, storing excess generated energy and releasing it back to the grid when renewable sources are unavailable, thus maintaining stable system operation [14,15,16].

Classification of Energy Storage Technologies

Energy storage technologies can be classified based on two main criteria: type and capacity.

1. Type-based classification:

- Chemical energy storage
- Thermal energy storage
- Mechanical energy storage

2. Capacity-based classification:

- Thermal energy storage
- Electrical energy storage

Among these, mechanical energy storage technology is considered more cost-effective than other types. Mechanical energy storage can be further divided into three categories (Figure 1):

1. Gravitational potential energy storage
2. Kinetic energy storage
3. Elastic energy storage

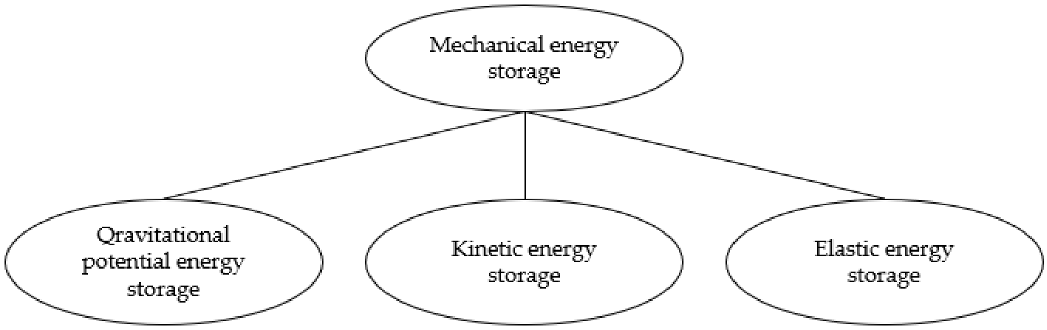

Figure 1. C*lassification of mechanical energy storage technology*

Gravitational Potential Energy Storage

Gravitational potential energy storage technology comprises two main types:

1. Pumped hydroelectric power
2. Solid gravity energy storage

Solid gravity energy storage technology offers advantages over pumped storage and other energy storage technologies due to its economic efficiency and geographical flexibility. Despite being a relatively new technology, it is developing rapidly. The main advantages of solid gravity energy storage are its cost-effectiveness and long operational lifespan [14,15,16].

Solid gravity energy storage technology stores potential energy generated by changing the height of a heavy object in a gravitational field. This process involves converting excess energy from the grid into mechanical energy through an engine-generator system.

Types of Solid Gravity Energy Storage Technologies

There are eight primary types of solid gravity energy storage technologies:

1. Tower Solid Gravity Energy Storage (T-SGES) [17,18,19]
2. Shaft Solid Gravity Energy Storage (S-SGES) [18,19]
3. Rope-hoisting Piston Solid Gravity Energy Storage (RP-SGES) [20,21]
4. Mountain Mine-Car Solid Gravity Energy Storage (MM-SGES) [19,22]
5. Linear Electric Machine-Based Solid Gravity Energy Storage (LEM-SGES) [19,23]
6. Compressed Air Piston Solid Gravity Energy Storage (CAP-SGES) [20,24]
7. Mountain Cable-Car Solid Gravity Energy Storage (MC-SGES) [19,25]

8. Piston Solid Gravity Energy Storage (P-SGES) [24,26]

A critical component of these energy storage technologies is the weight system. The choice of weights significantly influences the technical performance of the storage system. Materials such as sand, concrete, and iron are commonly used due to their efficiency as weights.

Proposed Design: Novel Solid Gravity Energy Storage System

This study presents a new design for a solid gravity energy storage device specifically tailored for use with renewable energy sources, particularly solar and wind energy (Figure 2). The system utilizes excess electricity generated on the grid to lift a massive concrete block, storing energy as gravitational potential energy.

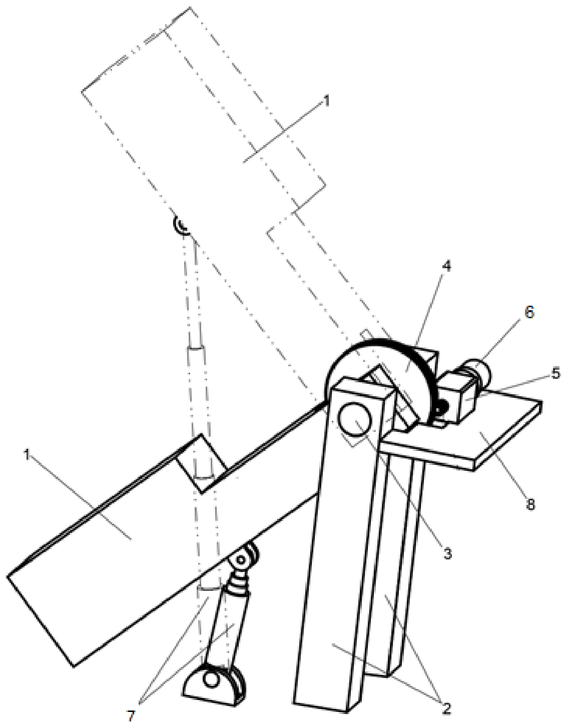

Figure 2: *New design solid gravity energy storage system*

System Components and Operation

The key components of the system include:

1. A concrete block (mass: 1000-3000 tons)
2. Concrete supports
3. A control shaft
4. A gear wheel
5. A reducer with gear wheel
6. An electric motor-generator
7. A hydraulic mechanism for controlled descent
8. A stand to keep the reducer and electric motor at a certain distance

The system operates in two main phases:

Energy Storage Phase

1. Excess energy from the grid powers the electric motor-generator.
2. The motor's rotation is transmitted through the reducer to the gear wheel on the control shaft.
3. As the shaft rotates, it lifts the concrete block.
4. The rising concrete block gains gravitational potential energy.

5. When the block reaches a defined height, the system is fully charged and disconnects from the grid.

Energy Release Phase

1. During a power shortage, the stored mechanical energy is converted back to electrical energy.
2. The concrete block descends, controlled by the hydraulic mechanism.
3. The descending motion drives the electric motor-generator, producing electricity.
4. The generated electricity is fed back into the grid.

System Specifications

- Concrete block mass: 1000 - 3000 tons
- Required construction area: approximately 300 m^2

Mathematical Model

The energy storage capacity of the system is defined by:

$$E = \eta mgh \tag{1}$$

Where: E - is the energy storage capacity; η - is the system's output efficiency; m - is the mass of the concrete block; g - is the acceleration due to gravity; h - is the height change of the concrete block.

The average output power of the system is given by:

$$\bar{P} = \frac{E}{T} \tag{2}$$

Where: $\bar{P}$ - is the average output power; E - is the energy storage capacity; T - is the system's energy discharge time.

According to expression (2), the instantaneous output power is determined by:

$$P = \frac{dE}{dt} \tag{3}$$

For circular motion of the concrete block, the average output power can be expressed as:

$$\bar{P} = M\omega \tag{4}$$

Where: M - is the torque generated during the rotation of the concrete block; ω - is the angular velocity of the concrete block.

This novel solid gravity energy storage technology has been developed to enhance the efficiency of renewable energy sources. The system's energy storage capacity can be adjusted by varying the weight of the concrete block, offering flexibility in design and implementation.

The presented energy storage device represents a promising solution in the fight against climate change and global warming, offering an efficient means of storing and releasing energy from renewable sources.

III. Results

The novel solid gravity energy storage system proposed in this study emerges as a promising solution to the challenges faced in renewable energy storage. Our analysis reveals a multitude of advantages that collectively position this system as a potentially transformative technology in the renewable energy sector.

At the core of the system's appeal lies its structural simplicity. By incorporating straightforward components, the design facilitates easier construction and maintenance processes. This simplicity extends beyond mere ease of assembly; it translates into tangible economic benefits. The minimal maintenance requirements and streamlined construction process result in cost-effective energy storage capabilities, enhancing the system's overall economic efficiency.

One of the most striking features of the proposed system is its compact design. Unlike many traditional energy storage systems that require vast geographical areas, our system's small overall dimensions significantly reduce the space needed for installation. This spatial efficiency opens up a wider range of potential locations for deployment, from urban settings to remote areas with limited available space. Importantly, this compact design does not come at the expense of storage capacity. Our analysis indicates that the system provides substantial energy storage capacity relative to its initial cost, striking an impressive balance between size and performance.

The system's design also prioritizes longevity and safety. Its robust construction and simple mechanics contribute to an extended operational life, a crucial factor in the long-term viability of energy storage solutions. This longevity is further enhanced by the low maintenance requirements of the structural components, which do not necessitate frequent or complex technical inspections. Beyond durability, safety considerations were paramount in the system's design. The proposed configuration incorporates features that effectively reduce potential risks associated with energy storage, an essential aspect for widespread adoption in various settings.

IV. The discussion of the results

To contextualize these advantages, we conducted a comprehensive comparative analysis against existing solid gravity energy storage technologies. This comparison encompassed a range of systems, including Tower (T-SGES), Mountain Cable-Car (MC-SGES), Shaft (S-SGES), Rope-hoisting Piston (RP-SGES), Mountain Mine-Car (MM-SGES), Linear Electric Machine-Based (LEM-SGES), Compressed Air Piston (CAP-SGES), and Piston (P-SGES) systems. Our analysis focused on critical factors such as structural complexity, economic efficiency, required geographical area, energy storage density, and useful lifespan.

The results of this comparison further highlight the potential of our proposed system. Many existing technologies, while innovative, face significant limitations, particularly in terms of geographical requirements and construction challenges. They often necessitate extensive land areas for installation and present considerable hurdles during the construction phase due to their complex structural designs. In contrast, our system's compact dimensions and simpler construction process offer a more versatile solution, adaptable to a diverse range of locations and applications.

Moreover, the scalability of our proposed system emerges as a significant advantage. Its design allows for relatively easy scaling, potentially enabling customization to meet various energy storage capacities. This flexibility could prove invaluable in adapting to different energy demands and grid requirements, a crucial feature in the ever-evolving landscape of renewable energy.

While these theoretical advantages are promising, we acknowledge the need for further research to fully validate the system's benefits. Future investigations should focus on several key areas. Prototype development and testing will be crucial to validate the theoretical performance metrics presented in this study. A comprehensive cost analysis, encompassing construction, operation, and maintenance expenses over the system's entire lifecycle, will provide a holistic view of its economic viability. Environmental impact assessments will ensure the system's alignment with sustainable development goals. Optimization studies could potentially enhance energy storage density and overall system efficiency, while integration studies with various renewable energy sources will assess the system's real-world compatibility and performance.

In conclusion, our novel solid gravity energy storage system shows considerable promise in addressing key challenges associated with renewable energy storage. Its simplicity, potential cost-effectiveness, and space efficiency position it as a valuable addition to the portfolio of energy storage technologies. As the global energy landscape continues to evolve towards sustainability, innovative solutions like the one proposed in this study could play a crucial role in accelerating the transition to a more sustainable energy future. However, it is important to emphasize that while our theoretical analysis suggests significant advantages, the realization of these benefits hinges on the outcomes of the proposed future research directions. The journey from concept to implementation is complex, but the potential rewards in advancing renewable energy storage are substantial.

However, it is important to emphasize that while our theoretical analysis and comparisons suggest significant advantages, the realization of these benefits hinges on the outcomes of the proposed future research directions. The development of prototypes, comprehensive cost and environmental impact analyses, optimization studies, and integration tests with renewable energy sources will be crucial in validating and refining the system's performance.

As the global energy landscape continues to evolve towards sustainability, innovative energy storage solutions like the one proposed in this study will play an increasingly vital role. By addressing the intermittency challenges associated with renewable energy sources, such systems have the potential to accelerate the transition away from fossil fuels and towards a more sustainable energy future. The promising results presented here provide a strong foundation for further research and development in this critical field.

Abstract

This study explores the intricate relationship between medical practices and human capital development, highlighting how healthcare systems significantly impact economic growth and sustainability. By examining various medical practices across different regions and historical contexts, the research aims to understand their effects on individual health, productivity, and overall economic performance. The analysis begins with a review of existing literature on the interplay between health outcomes and economic development, emphasizing the role of a healthy population as a cornerstone of human capital. Key indicators of human capital—such as education, workforce participation, and productivity—are assessed to establish how medical practices influence these dimensions. Additionally, the study employs case studies to illustrate successful healthcare models that have effectively enhanced human capital. It examines how investments in preventive care, access to quality medical services, and health education contribute to a healthier workforce, thereby promoting sustainable economic development. Through quantitative and qualitative methodologies, the research identifies barriers to effective medical practice implementation and suggests strategies for integrating healthcare improvements into broader economic policies. Ultimately, the findings aim to provide policymakers, healthcare professionals, and stakeholders with insights on optimizing medical practices to foster human capital development and achieve long-term sustainable economic growth.

Keywords: medical practices, human capital, sustainable development, health influence, economic productivity, access to healthcare, population health, health investments

I. Introduction

The intersection of medical practices and human capital is increasingly recognized as a critical factor in achieving sustainable economic development. As nations strive for economic growth and improved living standards, the health of their populations emerges as a foundational element that drives productivity, innovation, and social well-being. Medical practices encompass a wide range of healthcare services, interventions, and policies designed to promote health, prevent diseases, and manage existing health conditions. These practices not only influence the physical well-being of individuals but also significantly impact their cognitive abilities, educational attainment, and overall economic contributions.

Human capital, defined as the collective skills, knowledge, and experience possessed by individuals, is essential for fostering economic development. Healthier populations tend to exhibit higher levels of productivity, as good health enhances the ability to learn, work, and engage in economic activities. Conversely, poor health outcomes can hinder individuals' capacity to participate in the labor force and can lead to increased healthcare costs, reduced income, and lower economic output.

Moreover, sustainable economic development requires a holistic approach that integrates health into economic planning. Policies that prioritize medical practices not only enhance individual well-being but also contribute to broader economic goals such as poverty reduction, gender equality, and social equity. As such, understanding the influence of medical practices on human capital is vital for policymakers, healthcare professionals, and economists alike.

This investigation aims to explore the various dimensions through which medical practices affect human capital and, consequently, their contribution to sustainable economic development. By examining existing literature and empirical evidence, this study seeks to highlight the importance of investing in healthcare systems, improving access to medical services, and promoting health literacy. Ultimately, this exploration underscores the integral role of health in shaping a resilient and sustainable economy, emphasizing that the well-being of individuals is inextricably linked to the prosperity of societies. The complex of modern vectors of socio-economic development of Russia includes the increase of human capital, which can be achieved through the improvement and development of the healthcare system. Among the problems arising in the modern regional sphere of medical care, there is insufficient resource provision of medical and preventive institutions, an increase in the number of paid services, a shortage of primary care specialists and their low salaries, which leads to reduced motivation of personnel for high-quality work. Taking into account the above problems, in January 2019, the national project (NP) "Healthcare" was launched, which includes 9 federal projects (FP) and was developed by the Ministry of Health of the Russian Federation in order to implement the Decree of the President of the Russian Federation dated May 7, 2018 No. 204. The activities of the national project under consideration are aimed, first of all, at increasing the population and ensuring maximum accessibility of medical and preventive institutions for citizens. In this regard, the study of indicators of medical care in the Republic of North Ossetia-Alania (ROA) in the context of the implementation of the NP "Healthcare" is very relevant.

II. Methods

Open data from the EMISS register of the Federal State Statistics Service, as well as the portal of the budget system of the Russian Federation "Electronic Budget" were taken into account for indicators reflecting the effects of the implementation of federal projects of the NP "Healthcare" in the Republic of North Ossetia-Alania and the Russian Federation for the period from 2020-2023. Relative deviations were calculated for the studied indicators using MS Excel 2016 and SPSS " Statistics " software.

III. Results

A very large federal project is the "Development of the Primary Health Care System" (FP N1), which includes ensuring optimal accessibility of primary care for all segments of the population, including citizens living in remote areas, as well as increasing the coverage of the number of patients who have undergone preventive examinations. Table 1 presents an analysis of the dynamics of changes in the indicators characterizing the development of FP N1. As can be seen from the table, in the Republic of North Ossetia-Alania, starting from 2021 to 2023, the share of citizens undergoing annual medical examinations and professional examinations has been steadily increasing by 11% and 54%, respectively. A similar trend can be seen in the Russian Federation as a whole. In addition, the share of outpatient institutions that took part in the implementation of the "New Model of Organizing Medical Care" has significantly increased in the republic by 26% (2022) and 27% (2023).

Table 1: Dynamics of changes in indicators for the primary health care development system

Name	2021 %	2022		2023	
		%	Relative deviation to 2021, %	%	Relative deviation to 2022, %
(N1) The proportion of citizens who undergo annual preventive medical examination and/or medical check-ups in the total population					
RF	26.3	34.7	132	46.3	133
RSO-A	25.8	28.6	111	44	154
(N1) The share of polyclinics and polyclinic departments participating in the creation and replication of the "New Model for Organizing the Provision of Medical Care"					
RF	61.7	70.8	115	75.1	106
RSO-A	45.9	57.9	126	73.7	127

Analyzing the implementation of Federal Program No. 1, it can be said that in the Republic of North Ossetia-Alania there is a tendency towards the development of primary health care, which is confirmed by a number of transformations according to the data of the Ministry of Health of the Republic of North Ossetia-Alania, including the construction of a medical outpatient clinic in the village of Predgornoye (Mozdok district), the renovation of medical outpatient clinics in the villages of Vinogradnoye, Priterechny (Mozdok district), and Nogir (Prigorodny district); a feldsher-midwife station in the village of Krasnykh Khod (Alagirsky district); polyclinics in the village of Oktyabrskoye (Prigorodny district), and the village of Chikola (Irafsky district).

Another important milestone of the NP "Healthcare" was FP N2 "Combating cardiovascular diseases", which implies equipping cardiology and vascular departments of medical institutions, as well as the formation of conditions for the prevention of cardiovascular diseases in the population. As can be seen from the data in Table 2, starting from 2020, mortality from diseases of the circulatory system in the RNO-A has had positive dynamics. Thus, in 2021, compared to the previous year, mortality decreased by 2%, and in the following years by 7% (2022) and 16% (2023). A similar trend can be seen in the Russian Federation as a whole, with the exception of 2021, when mortality remained virtually unchanged.

Speaking about FP N3 "Combating Cancer", it is important to note that the project is aimed at re-equipping regional oncology centers, organizing outpatient care centers for cancer patients, developing reference centers for effective diagnostics of malignant neoplasms. RUB 983.4 billion was allocated for the implementation of this project, which is half of the financial support for NP "Healthcare". According to statistics, starting from 2020, the share of malignant neoplasms detected at stages I - II has slightly decreased in 2021 (1%), and increased by 3% and 8% in 2022 and 2023, respectively, compared to 2020. Similar positive dynamics are observed throughout the country, which indicates the effective implementation of FP N3.

IV. Discussion

The development of medical care for the population under 18 years of age is also reflected in the directions of the NP "Healthcare". Thus, within the framework of the implementation of FP N4 "Development of children's health care, including the creation of a modern infrastructure for the provision of medical care to children", it is expected to reduce infant mortality to 4.5 cases per 1 thousand newborns; reconstruction and improvement of children's hospitals, clinics, departments; training of health workers in simulation centers of Russia. Analyzing the mortality of children in the Republic of North Ossetia-Alania from 0 to 17 years old, we can say that in 2021, compared to the previous year, this figure increased by 21%, a similar negative trend is observed in subsequent years. Thus, in 2022, mortality increased by 18%, and in 2023 - by 1% compared to 2020. However, comparing the data for 2022, it can be said that child mortality has decreased by 2% compared to 2021, and by 15% in 2023 compared to the previous year. In addition, according to statistics, 100% of children's healthcare institutions are equipped with modern infrastructure for providing medical care to children.

Table 2: *Dynamics of temporary changes in some indicators reflecting the development of federal projects of the NP "Healthcare"*

Name	2020, person	2021		2022		2023	
		person	Relative deviation to 2020, %	person	Relative deviation to 2020, %	person	Relative deviation to 2020, %
(N2) Mortality from diseases of the circulatory system (per 100 thousand population)							
RF	640.8	640.3	100	566.8	88	556.7	87
RSO-A	596.6	586.2	98	553.7	93	499.4	84
(N3) Proportion of malignant neoplasms detected at stages I - II							
RF	56.3	57.9	103	59.3	102	60.5	102
RSO-A	54.6	54	99	55.5	103	59.1	108
(N4) Mortality rate of children 0-17 years (per 10,0000 population of the corresponding age)							
RF	44.6	47.1	106	43.4	97	40.7	91
RSO-A	36.1	43.6	121	42.7	118	36.5	101
Name	**2020, %**	**2021**		**2022**		**2023**	
		%		**%**	**Relative deviation to 2022, %**	**%**	**Relative deviation to 2022, %**
(N4) Number (proportion) of children's clinics and children's clinic departments with a modern infrastructure for providing medical care to children							
RF	-	89.2		98.1	110	98.3	100
RSO-A	-	100		100	100	100	100
(N5) Staffing of medical organizations providing outpatient medical care with doctors							
RF	81.1	81.1	100	82.2	101	89.3	109
RSO-A	90.6	89.7	99	96.9	108	100	103
(N5) Staffing of feldsher stations, feldsher-midwife stations, and medical outpatient clinics with medical workers							
RF	84.6	85.2	101	85.6	101	91.4	107
RSO-A	90.9	95.5	105	96	101	100	104

Note: "-" - the corresponding indicator is not present in the statistical report

The issue of staffing in the problems of organizing medical care has been particularly acute in recent years. In this regard, FP N5 "Provision of medical organizations of the healthcare system with qualified personnel" includes training specialists using distance learning technologies, increasing the number of accredited specialists, and developing interactive educational modules. Assessing the degree of staffing of outpatient organizations and departments with qualified doctors, it can be said that the share of such specialists in the Republic of North Ossetia-Alania in 2021 slightly decreased (1%), and in 2022 and 2023 compared to 2020 increased by 8% and 3%, respectively. Positive dynamics are observed in the change in the staffing of medical workers in feldsher-obstetric stations and medical outpatient clinics. Compared to 2020, the share of such specialists increases significantly up to 2023, which indicates the successful implementation of FP N5.

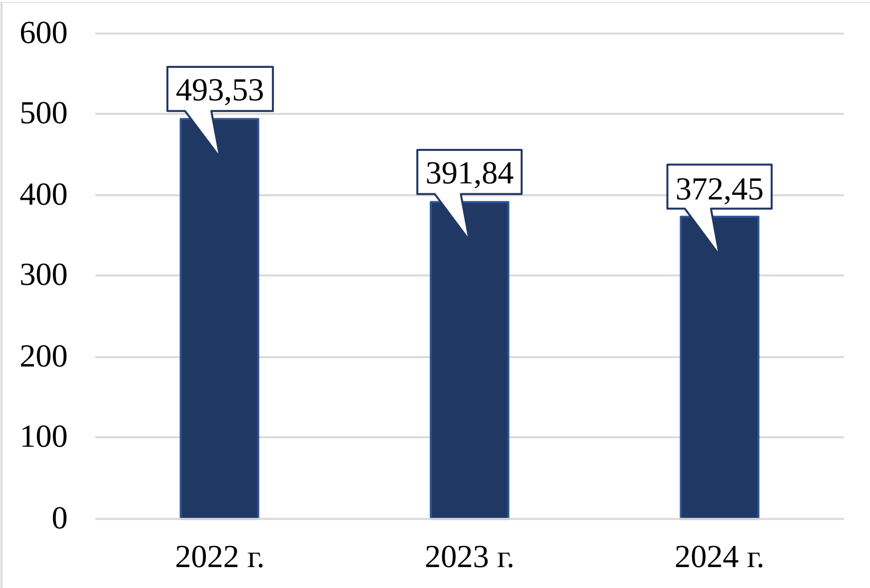

Figure 1: *Financial support for the Federal Program "Modernization of Primary Healthcare in the Russian Federation" (N9) in the Republic of North Ossetia-Alania, million rubles*

In 2022, a new federal project "Modernization of the Primary Healthcare of the Russian Federation" (FP N9) was included in the NP "Healthcare", the implementation of which is expected to increase the availability of medical care for all groups of citizens through the creation of the optimally necessary infrastructure. As can be seen from the histogram (Fig. 1), the volume of financial support for FP N9 from 2022 to 2024 has a negative trend. Thus, in 2023, the volume of funding decreased by almost 21% compared to 2022, and as of October 2024 - by 5% compared to the previous year.

Within the framework of the implementation of federal projects of the NP "Healthcare", such as FP N1, N2, N3, positive dynamics in improving the availability of medical care and reducing mortality from certain diseases are observed. In particular, the share of citizens undergoing medical examinations and preventive examinations annually in the republic is steadily increasing, which indicates a very successful implementation of the corresponding FP. An important aspect is also the fight against cardiovascular and oncological diseases, which has led to a significant decrease in mortality from diseases of the circulatory system, as well as to a decrease in cases of confirmation of malignant neoplasms. However, a number of indicators related to child mortality require closer attention, despite the positive changes in equipping children's institutions with modern infrastructure. Thus, the set of measures implemented within the framework of the NP "Healthcare" has a positive impact on improving the quality and availability of medical care in the Republic of North Ossetia-Alania. To ensure long-term results from the implementation of projects, further integration of digital technologies and modern approaches to healthcare management is necessary, which will ensure the availability of medical services for the population, especially in remote regions. In addition, it is important to develop new training programs and improve the qualifications of medical personnel, with an emphasis on training primary care specialists.

The relationship between medical practices, human capital, and sustainable economic development is multifaceted and critical for understanding how health influences economic outcomes. This discussion delves into several key areas, including the mechanisms by which medical practices enhance human capital, the socio-economic implications of health interventions, and the policy considerations necessary to promote sustainable development.

1. Mechanisms of Influence

Medical practices influence human capital primarily through improving health outcomes and increasing productivity. Effective healthcare services reduce the incidence and severity of diseases, leading to a healthier workforce. This has several direct implications:

- Increased Productivity: Healthier individuals are often more productive at work. They tend to have lower absenteeism rates and higher performance levels, which contributes positively to economic output. Research has shown that every dollar invested in health can yield significant returns in productivity.
- Cognitive Development: Access to quality healthcare, especially during critical developmental periods (such as childhood), significantly affects cognitive abilities. Healthy children are more likely to perform better in school, leading to higher educational attainment and the development of a skilled workforce.
- Life Expectancy and Workforce Participation: Improved medical practices can extend life expectancy, encouraging older individuals to remain in the workforce longer. This can help alleviate labor shortages and ensure the sustainability of social security systems.

2. Socio-Economic Implications

The impact of medical practices on human capital extends beyond individual health outcomes; it also influences broader socio-economic factors:

- Equity and Access: Disparities in access to medical practices can exacerbate social inequalities. Populations with limited access to healthcare services often experience worse health outcomes, which can hinder their economic contributions. Ensuring equitable access to healthcare is essential for maximizing human capital across all segments of society.
- Public Health Investments: Countries that invest in preventive healthcare (e.g., vaccinations, health education) tend to experience lower healthcare costs in the long run. By reducing the prevalence of diseases, these investments not only improve population health but also relieve pressure on healthcare systems and public finances.
- Interconnectedness with Other Sectors: Health intersects with various sectors, including education, employment, and social services. For example, a healthy workforce supports economic growth, which in turn can enhance funding for education and infrastructure, creating a virtuous cycle of development.

3. Policy Considerations

To leverage the influence of medical practices on human capital for sustainable economic development, several policy considerations should be prioritized:

- Strengthening Healthcare Systems: Governments must invest in healthcare infrastructure, ensuring that all individuals have access to quality medical services. This includes funding for hospitals, clinics, and preventive care programs.
- Promoting Health Education: Increasing health literacy is crucial for empowering individuals to make informed health choices. Educational initiatives can foster better health practices, leading to improved individual and community health outcomes.
- Integrating Health into Economic Planning: Policymakers should recognize health as a critical determinant of economic growth. Strategies that promote health in economic development plans can enhance overall productivity and ensure a sustainable future.
- Evaluating Outcomes: Ongoing research and evaluation of health interventions are essential to understand their impact on human capital and economic development. Policymakers should utilize data-driven approaches to assess the effectiveness of healthcare investments and adjust strategies accordingly.

The influence of medical practices on human capital and their contribution to sustainable economic development is profound and far-reaching. By improving health outcomes, enhancing productivity, and addressing socio-economic inequalities, effective medical practices lay the foundation for a resilient and thriving economy. As nations navigate the challenges of economic growth in an increasingly interconnected world, prioritizing health as a cornerstone of development will be crucial for fostering sustainable progress. Policymakers must recognize this relationship and implement strategies that align healthcare initiatives with broader economic goals, ensuring that health and prosperity go hand in hand.

Abstract

In times of economic crises and unstable market conditions, companies face many factors that exacerbate their financial vulnerability. Currency volatility, lower consumer demand and higher cost of credit resources create additional financial burdens on organizations. debt default and inability to maintain normal operations. Moreover, the bankruptcy of one company can cause a chain reaction, affecting its counterparties. Thus, the bankruptcy of even one organization exacerbates crisis phenomena, increases systemic risks and threatens both individual sectors of the economy and the economy as a whole. This necessitates the development of strategies to minimize the risk of bankruptcy of economic entities.

Keywords: bankruptcy of an organization, financial risks, risk minimization strategies, risk management, financial management, organization, microeconomics

I. Introduction

In economic science, bankruptcy is considered as a process during which an enterprise loses its solvency and cannot continue its activities without the intervention of external structures - creditors, insolvency practitioners or third-party investors. Bankruptcy is the final stage of the financial crisis of the enterprise, in which its liabilities significantly exceed assets, which leads to the impossibility of independent restoration of financial stability. As a result of bankruptcy, there is a redistribution of property and resources, which can significantly affect the socio-economic situation of the company's employees. The bankruptcy of large enterprises leads to a sharp reduction in jobs, a decrease in tax revenues to the budget and a deterioration in the socio-economic situation of the regions.

The factors of bankruptcy of an organization can be divided into two large groups: external and internal. External factors of bankruptcy of an organization are a set of macroeconomic, political, legal, social and market conditions that do not depend on the activities of the organization itself, but have a significant impact on its financial stability and ability to fulfill obligations to creditors. The classification of external factors is presented in Fig.1.

Thus, the financial condition of the organization is most influenced by macroeconomic factors - economic cycles, inflationary processes, fluctuations in exchange rates, the state of international trade and the availability of external financing. An economic recession reduces the purchasing power of consumers and slows down capital turnover, which negatively affects the company's earnings. Inflation increases the cost of raw materials and labor, and instability in foreign exchange markets increases the cost of imported goods and services. International sanctions and trade barriers limit the access of economic agents to the necessary resources, technologies and markets, which can lead to their bankruptcy.

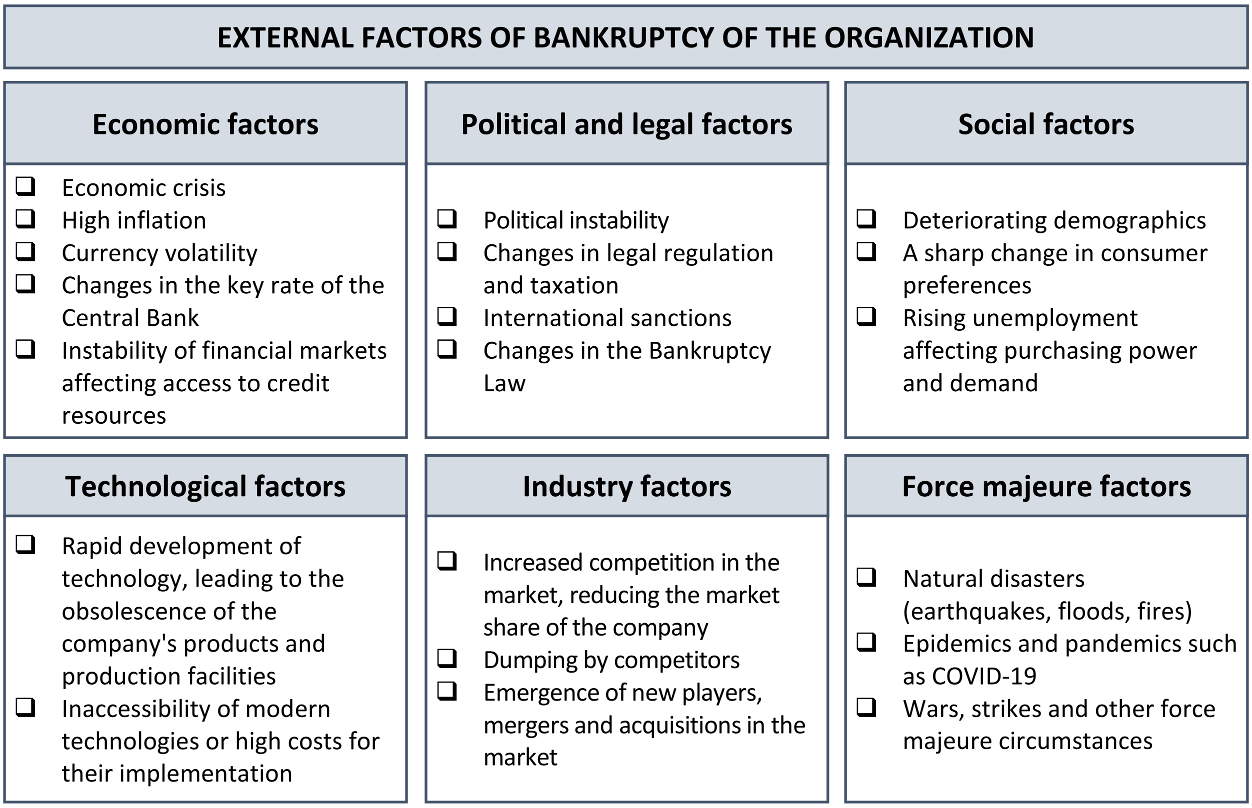

Figure 1: *External factors of bankruptcy of the organization*

II. Methods

Political and legal factors play a key role in shaping the environment in which business operates, and significantly affect the likelihood of bankruptcy risks. Frequent changes of power, political conflicts, social unrest or coups d'état can create an unfavorable environment for doing business, which leads to a reduction in investment, a decrease in confidence from international partners and, as a result, an increase in the risk of bankruptcy. The impact of political instability is particularly strong in countries with irregular legislative processes and poorly developed property rights protections.

Demographic changes (population ageing, migration processes) create imbalances in labor markets, complicating the search for skilled labor and changing consumption patterns. A decrease in demand for specific goods and services, transformations in consumer behavior can lead to a drop in company revenues. Social tensions also lead to lower economic activity and increased risks for businesses, especially in sectors sensitive to fluctuations in demand. The rapid pace of technological change creates risks for companies that do not have time to adapt to new conditions or ignore the implementation of innovations. For example, the development of innovative technologies and products leads to the displacement of traditional products, turning the current business model of the company into outdated and unprofitable. Many companies do not have enough funds to finance R&D and are forced to leave the market. Economic entities investing in innovative technologies may also not receive the expected results, which leads to a shortage of liquidity.

III. Results

Natural disasters, epidemics, man-made accidents, military conflicts, economic sanctions and other force majeure circumstances disrupt normal business processes, causing disruptions in supply chains, destruction of infrastructure and production facilities, as well as a sharp reduction in demand for goods and services. Thus, the COVID-19 pandemic has led to mass bankruptcies of organizations operating in the field of tourism, retail and catering due to the restrictions imposed and changes in consumer habits. Companies that do not have sufficient financial reserves or mechanisms to adapt to such circumstances are on the verge of insolvency and are forced to cease their activities.

The risks of bankruptcy of an organization are also influenced by internal factors related to its production, financial, marketing and other subsystems (Fig. 2).

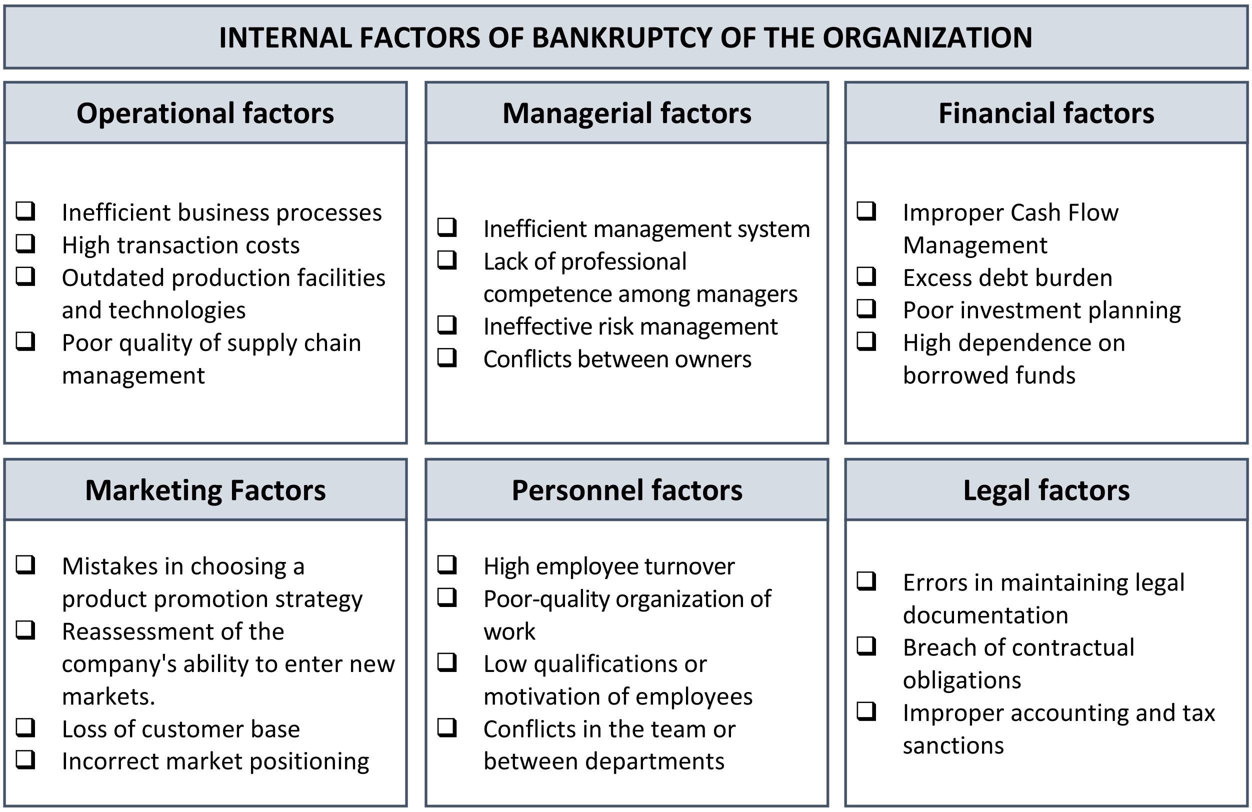

Figure 2: *Internal factors of bankruptcy of the organization*

Thus, the operational factors of bankruptcy are associated with shortcomings in the organization of the company's main business processes.

Managerial factors of bankruptcy are associated, first of all, with incompetent management and lack of strategic vision.

Marketing factors of bankruptcy are associated with the wrong positioning of the company in the market, unsuccessful marketing strategies and the inability to adapt to market transformations.

The legal factors of bankruptcy may be errors in the conduct of contractual work, violation of tax legislation, lack of intellectual property protection or conflict situations with counterparties. In addition, insufficient legal protection of assets, as well as mistakes during reorganization, exacerbate the crisis situation and lead to the bankruptcy of the company. A comprehensive understanding of external and internal factors of bankruptcy allows you to develop effective strategies to minimize their impact on the organization.

IV. Discussion

The first stage in any strategy for preventing the bankruptcy of an organization is the diagnosis of financial risks. The main source of information for assessing the financial condition and risks of the company is the data of accounting (financial) statements. The most common diagnostic method is the study of financial ratios of liquidity, financial stability, profitability and business activity

Strategies for minimizing the risk of bankruptcy are a set of measures aimed at strengthening the financial stability of the company, increasing its competitiveness and adaptability to changing external and internal conditions. The main goal of these strategies is to reduce the likelihood of crisis situations and prevent possible threats of bankruptcy. In today's highly uncertain economic environment, the successful implementation of these strategies can ensure the long-term stability of the company. The avoidance strategy is the organization's deliberate refusal to participate in operations, projects and partnerships that have a high level of uncertainty or potential losses. This approach avoids an unexpected deterioration in the financial situation, especially in conditions of economic uncertainty. A key element of the evasion strategy is a cautious attitude to attracting borrowed funds, investing current assets in forms that are difficult to implement, as well as participating in projects with uncertain profitability. Organizations that adhere to this approach focus on maintaining liquidity, reducing the debt burden and increasing financial stability. They prefer to cooperate with trusted counterparties who have a stable financial position and a positive reputation in the market. Analysis of financial indicators, research of market trends and assessment of possible risks are of key importance in making decisions on the choice of partners and projects.

Thus, the risk avoidance strategy allows them to reduce the likelihood of crisis situations and maintain stable functioning even in the face of adverse external influences. It should be noted that focusing exclusively on the risk avoidance strategy hinders active development and increase in market share, which has a negative impact on the organization in the long term. Therefore, in a market economy, there are mechanisms for transferring certain financial risks to other business entities using factoring, suretyship, insurance and other methods.

To reduce the risk of bankruptcy, companies can use various strategies, including avoidance, transfer, localization, diversification and compensation of risks. As part of a unified crisis management system, companies develop individual approaches to risk management that allow not only to avoid bankruptcy, but also to ensure sustainable growth in the face of uncertainty.

RESTORATION OF SOILS THAT HAVE LOST FERTILITY DUE TO UNFAVOURABLE CLIMATIC CONDITIONS

Najiba Shirinova
•

naciba.shirinova@aztu.edu.az

Abstract

The article is devoted to the search for alternative ways to prevent the negative impact of climate change on precipitation. It is known that as a result of climate change, both on the scale of the Earth and within any country, excessive precipitation falls on one part of the territory, and on the contrary, drought occurs on another. This affects the productivity of agriculture engaged in the cultivation of crops. The physical and mechanical properties of the soil play a key role in crop production. As a result of climate change in arid areas, it is possible to restore soil fertility and increase productivity by improving soil properties - moisture capacity, water evaporation, dehydration and others with the help of various chemicals. For this purpose, the titanium-substituted organic compounds synthesized by us were tested on gray-brown soils. The introduction of various amounts of the proposed preparations into the soil increased the physical and mechanical properties of the soil. As a result, the yield of agricultural crops increased. Accumulation of the introduced compounds as residues in plant products was not observed. Therefore, by safely using them, it is possible to develop agriculture in arid areas and obtain abundant harvests.

Keywords: climate change, drought, thiethane compounds, physical and chemical properties of soil

I. Introduction

Climate change, which affects all countries of the world and every person, has a negative impact on all sectors of the economy. In each country, these changes manifest themselves locally. The impact of climate change on human development depends on the geographical location of the state, the existing climatic conditions in the country and other factors. These changes will be more pronounced in four main areas in each country:

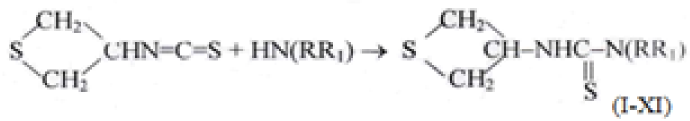
- There is a high probability of reduced agricultural productivity, especially crop production, with the emergence of drought and rainfall patterns in the area. Scientists estimate that by the 2080s, an additional 600 million people will suffer from acute malnutrition as a result of pressures on agriculture and food security caused by climate change [1].
- Shortage of drinking water is a problem. The cause of this problem will be an increase in the number of floods and deluges due to melting glaciers, as well as a decrease in the water level in many rivers during hot weather. This can be observed in the territory of Azerbaijan as well. The current decrease in the level of the Kura River has caused great problems among people living in the surrounding areas. If this problem is not prevented, the number of people suffering from water shortage will increase every year.

- The above problems will lead to the destruction of ecosystems in each area. This will lead to the destruction of biodiversity and the threat of extinction of many plant and animal populations. This will be especially noticeable in coastal areas.
- Climate change will also affect human health. The elderly, those suffering from nervous, cardiovascular, cardiac and respiratory diseases, and children are especially sensitive to these changes. In addition, the risk of infectious diseases is high in areas with floods and droughts.

The above-mentioned climate changes have a negative impact on agriculture. This has a particularly negative impact on the soil, which is the main element of agriculture. Providing the population of each country with food is one of the main directions of the state's economic policy. Work has been carried out in this direction in our republic. "The Food Security Program of the Republic of Azerbaijan" was approved by the Decree of the President of the country, and as a result of the work done within the framework of this Program, the production of agricultural and food products has increased significantly [2]. Reliable food supply is the main condition for economic stability and social stability of each country. In this regard, the Azerbaijani state is implementing comprehensive measures to ensure reliable food supply to its population and is implementing large-scale state programs aimed at developing the agricultural sector, on which food security directly depends. At present, reliable provision of the country's population with food is one of the main directions of the state's economic policy. Therefore, it is very important to constantly implement appropriate measures to fully meet the needs of each member of society for basic food products. In recent years, due to negative trends in the financial market of leading countries as a result of climate change, as well as increased demand for food as a result of population growth, increased floods and droughts, limited water resources and other reasons, prices for basic food products in world markets have begun to rise, and in some countries food shortages have begun to increase, which has become a real threat. Food production in our republic is below the existing potential and capabilities. There are few land plots in our country suitable for cultivation. 1.2 million hectares of land in the country are salinized to varying degrees, have been subjected to various types of erosion, more than 50 thousand hectares of land are polluted. In addition, the fertile layer of more than 1.4 million hectares of agricultural land has been damaged. It is necessary to take step-by-step measures to prevent the process of land degradation. These measures should include the adoption and implementation of land use rules, land management and preparation of relevant maps, as well as the implementation of measures aimed at land rehabilitation and improvement of land quality. One of such measures is the implementation of a set of measures and appropriate mechanisms for the protection and improvement of soil quality [3].

II. Methods

Organic sulfur compounds are used in agriculture for various purposes - pest control, fertilizer production, soil reclamation, etc. For this purpose, we synthesized titanium-substituted compounds. First, 1,2-epithio-3-chloropropane was prepared in an aqueous medium by the reaction of 1,2-epoxy-3-chloropropane with thiourea [4]. Then, 3-thiatanyl isothiocyanate was obtained by the action of ammonium thiocyanate on 1,2-epithio-3-chloropropane in water. The corresponding 3-thiatanyl thioureas were synthesized by the action of various single and binary amines on 3-thiatanyl isothiocyanate [4].



R=R$_1$=H (I); R=H, R$_1$=CH_3- (II), R=H, R$_1$=C_2H_5- (III), R=H, R$_1$=$C(CH_3)_3$- (IV), R=H, R$_1$=$C_{18}H_{37}$- (V), R=H, R$_1$=C_6H_5- (VI), R=H, R$_1$= $C_6H_5CH_2$- (VII), R=H, R$_1$= $C_{10}H_7$- (VIII), R= CH_3- , R$_1$= CH_3- (IX), R= C_2H_5-, R$_1$= C_2H_5-(X), R= C_4H_9-, R$_1$= C_4H_9-(X)

The coupling reactions of aliphatic amines with 3-thiatanyl isothiocyanate are carried out without a solvent, sometimes in benzene, the reaction is isothermal and is completed in 10-30 min. However, the interaction with aryl-substituted amines takes a relatively long time to complete, within 3-4 days. When triethiamine is used as a catalyst to increase the reaction rate, the reaction is completed within 1 day. The synthesized 3-thietanyl-substituted thioureas are white crystalline or oil-like substances. Thiourea can be dissolved in ethyl alcohol and purified by precipitation with benzene. The yield and physicochemical properties of the obtained substances are presented in the table (Table 1).

Table 1: *Physicochemical constants of 3-thiatanyl-substituted thiourea*

№	R	R$_1$	$T_{mel.}$ ^0C	Found, %				Calculated, %				Gross formula

The IR spectrum of the synthesized 3-thiethane-substituted thioureas retains the absorption bands at 670-680, 720-730 and 1420-1445 cm^{-1}, characteristic of the four-membered thiethane cycle. The spectrum also contains an absorption band in the region of 1500-1510 cm^{-1}, corresponding to the stretching vibrations of the NHC(S) fragment. The absorption band corresponding to the isothiocyanate functional group is not observed in the IR spectrum at 2090 cm^{-1}. In the IR spectrum of 3-thiatanyl-substituted thioureas, recorded in a KBr prism, a broad absorption band observed in the region of 3320-3330 cm^{-1} corresponds to the NH bond. When recording the IR spectrum of a 0.005 M solution of these substances in CCl_4, an absorption band is observed at 3380 and 3480 cm^{-1}, corresponding to vibrations of the free valence of the NH bond. In addition, an absorption band at

3040 cm^{-1} is also observed in the spectrum of the dilute solution. This indicates the presence of an internal hydrogen bond NH….S and is consistent with literature data [6]. In the IR spectrum of the compound containing the NH_2 group, unlike other thiatane-substituted ureas, absorption bands are found in the IR spectrum at 3370, 3435 and 3470 cm^{-1}. According to literature data [7]. the absorption bands at 3370 and 3470 cm^{-1} characterize asymmetric and symmetric stretching vibrations of the NH bond.

2.7-3.75 mg.h. in the NMR spectra of 3-titanium-substituted compounds. In the field, signals of protons of two equivalent methylene groups in the four-membered thietane ring are observed as a quintet in the ratio 1.4:6:4:1. The signal of the methine proton, located in the thietane ring, is 4.3-4.7 mg.h. as a quintet. appears in the field. The signal corresponding to the NH group in the thiourea fragment, located in the molecule of all synthesized thioureas, is singlet and is detected in the field of 7.05-7.75 mg.h.

One of the synthesized compounds (VII) was tested as a soil improver for gray-brown soils in greenhouse conditions. The preparation is given in the amount per hectare by dissolving the compounds in water 2.5; 5.0; 7.5; 15.0 kg. As a result of the studies, it was found that after the introduction of the compositions into the soil, the percentage of water-resistant particles >0.25 mm in size, moisture capacity, soil water permeability increases and the under-evaporation capacity decreases, which has a positive effect on soil fertility. Compared with the control, the yield of tomato plants per m^2 in the experimental area increased by 1.2-3.5 kg, and the yield of cucumber plants - by 1.9-4.0 kg.

Table 2: *Effect of 3-thiatanyl-substituted thiourea on the water-physical composition of gray-brown soil*

Scheme of the experiment	Mechanical fraction, volume in mm, %					The volume of waterproof aggregates in mm., %			
	1,0-0,25	0,25-0,01	0,01-0,001	0,001	0,01	>1,0	1,0-0,25	<0,25	>0,25
Option without preparation	37,7	31,5	20,0	10,8	30,8	18,2	34,8	47,0	53,0
Prototype 2,5 kq/hk	34,1	35,6	22,2	9,1	31,3	20,0	35,07	46,3	53,7

Preparation 15 kq/hk	2,9	27,9	37,1	32,1	69,2	7,0	72,7	28,7	71,3

The quality of the grown products also improved. Currently, processed cumbrin [8], lignosulfonate [9] and acrylic acid [10] are used for this purpose. Lignosulfonate, taken as a prototype and improver of loamy soils by the mechanism of action, is expensive and has a limited raw material base. In addition, the technology for obtaining lignosulfonate is multi-stage and uses expensive metal salts (Fe, Cu, Zn) and polyethyleneamine. The experiments were repeated 4 times on an area of 10 m^2. The results obtained on the effect of the newly synthesized compound and the prototype on the mechanical composition of the soil, water-resistant aggregates and the productivity of vegetable plants are presented in the following experiments.

III. Results

Experiment 1.

The effect of the proposed compound on the water-physical composition of the soil was studied. The mechanical analysis of the soil was determined by treating a pipette with sodium pyrophosphate, and the water-resistant aggregate was determined by the Sabbinova method [11]. The results obtained are presented in the table (table 2). As can be seen, the amount of particles 0.001-0.01 mm in size in the control variant was 9.1-11.7 and 30.4-31.3%, and taking into account the effect of the new combination, this figure was 18.4-32.1 and 38.1-69.2%. If in the control variant the amount of water-resistant aggregate 40.25 mm thick was 51.8-55.1%, then under the influence of the new preparation it was 51.6-77.8%.

Experiment 2.

The effect of the synthesized compound on the moisture capacity, water evaporation and water permeability of the soil was studied and the results obtained are presented in the table (table 3). As can be seen from the table, the new preparation increased the moisture capacity of the soil, reduced water evaporation and increased dehydration, which led to an increase in soil fertility.

Table 3: *The effect of 3-thiatanyl-substituted thiourea on the moisture capacity, water absorption and water evaporation capacity of gray-brown soil*

Scheme of the experiment	Moisture capacity, %	Evaporation,%	Humidity, %	Waterproof	
				ml/ minute	ml / per day
Option without preparation	24,5	9,4	6,1	0,5	17,1
Prototype 2,5 kq/hk	24,4	7,8	6,3	0,8	19,3
Prototype5,0 kq/hk	25,7	8,4	6,7	0,7	20,7
Prototype 7,5 kq/hk	27,3	8,7	7,2	1,3	28,4
Prototype 15 kq/hk	25,0	7,8	7,1	1,0	24,6
Preparation 2,5 kq/hk	24,9	5,4	8,4	0,7	26,4
Preparation 5,0 kq/hk	32,5	4,2	8,6	1,2	30,2
Preparation 7,5 kq/hk	44,6	3,2	9,2	1,8	35,1
Preparation 15 kq/hk	40,3	2,4	8,1	1,5	31,6

Experiment 3.

The effect of the studied compound on the productivity and quality of vegetable plants - tomatoes and cucumbers - was also studied. The results obtained are presented in the table (table 4). As can be seen from the obtained result, the productivity of tomato and cucumber plants increased by 1.2-3.5 and 2.6-4.9 kg/m^2, respectively, compared to the prototype. At the same time, as a result of mathematical calculations using the method of V.V. Pereguov, it was established that the quality of vegetable plants also increased.

Experiment 4.

The effect of the new preparation on the accumulation of residues in vegetable plants was determined colorimetrically using the method of O.A. Drozdova [11]. The results obtained are presented in the table (table 5). The results show that the new compound does not accumulate as a residue in plant organs.

Table 4: *The effect of 3-thietanyl-substituted thiourea on the yield and quality of vegetable plants in gray-brown soil*

Experiment 5.

The toxic effect of the new compound was studied in the field. The results are summarized in a table and it is clear from the results that the new compound does not have a toxic effect (Table 6).

Table 6: *Toxic effect of 3-thiethane-substituted thiourea on vegetable plants, (LD_{50} – kq/hk)*

Prototype	18,7
Preparation	20,5

From the experiments conducted and the results obtained, it can be concluded that the newly synthesized compounds increase the fertility of arid territories and uncultivated soils, making them vulnerable to cultivation and increasing the productivity of crops. We cannot accept the consequences of climate change. In addition to solving this problem with solidarity and joint cooperation of all countries of the world, it is necessary to find ways to solve problems using new achievements of science and technology.

Absract

The morphostructural, genetic characteristics and oil-gas potential of local folds of the Buzovna-Mashtaga-Janub-2 anticlinal zone have been studied. These studies made it possible to predict promising oil and gas-bearing objects within individual local structures. This anticlinal zone is situated in the northeastern part of the Absheron Peninsula and consists of en-echelon local folds such as Buzovna–Mashtaga, Gala, Turkan, Zira, Janub and Janub-2. The presence of a regional left-lateral strike-slip fault between the Zira and Janub folds contributed to the displacement of the Janub and Janub-2 folds in the northeast direction and lead to the separation of these structures from studied anticlinal zone. However, they are a tectonic continuation of the anticlinal zone.

The level of dislocation of the studied folds decay in the northeast direction due to a decrease in the intensity of the cross buckle mechanism that forms these structures as they move away from the Greater Caucasus collision.

Due to the complexity of the oil and gas bearing structures under consideration with hemianticlines and taking into account that the latter, as a rule, transform into local folds with stratigraphic depth, they are promising objects for oil and gas prospecting and exploration. The natural reservoirs of the local folds under consideration are saturated with hydrocarbons in accordance with the principle of differential entrapment by S.P. Maksimova - V. Gassou.

Keywords: cross buckle mechanism, natural reservoirs, productive series suites, differential entrapment, Apsheron Peninsula

I. Introduction

The tectonic structure of the Apsheron oil and gas bearing region is characterized by the widespread development of infolded- disjunctive dislocations, injection structures and mud volcanism. There are as well as anticlinal zones, which are characterized by weak developed and buried folds. They are complicated by a small number of relatively low-amplitude faults and are mainly “closed” structures, such as the folds of the Buzovna–Mashtaga–Turkan–Zira–Janub-2 anticlinal zone [1,6].

The studied zone is located in the northeast of the Apsheron Peninsula, extends in a southeastern direction, and includes the local folds of Buzovna–Mashtaga, Gala, Turkan, Zira, Janub and Janub-2.

The Buzovna-Mashtaga fold has a complex structure, while consists by two-dome. The domes are separated from each other by a shallow saddle. In fact, the structure consists of a buried brachyanticlinal Buzovna fold and the Mashtaga structural uplift (Fig. 1) [2, 3].

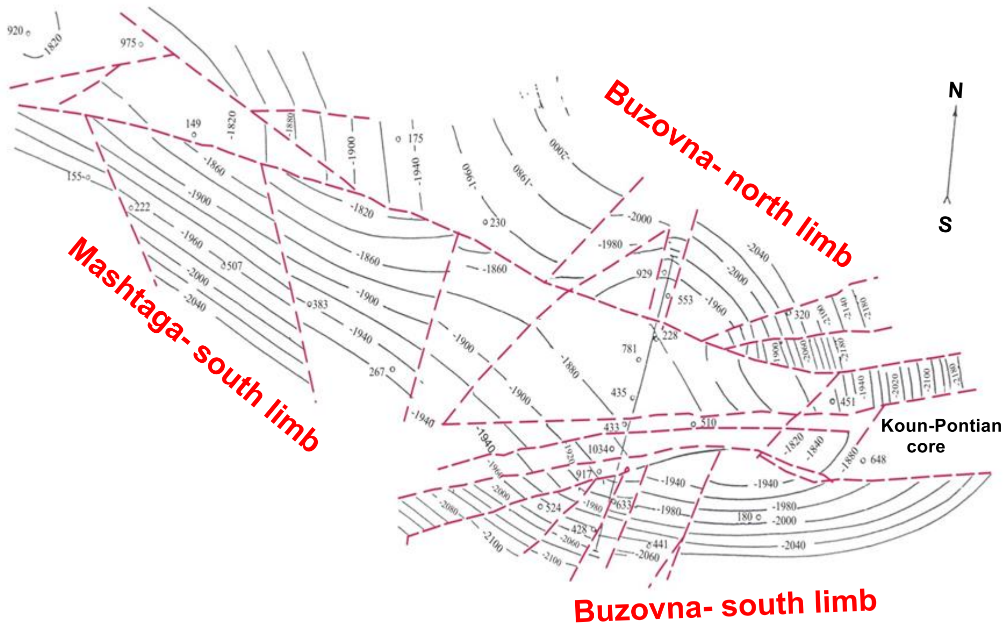

Figure 1:. *Buzovna–Mashtaga field. Structural map constructing by the roof of the PK suite*

II. Method

The goals of the work are to study the morphostructural and genetic characteristics of development, level of complexity, oil and gas saturation of local folds in this anticlinal zone and identifying new promising objects. For this purpose, the study area was analyzed in the direction of Buzovna–Mashtaga–Turkan–Zira–Janub-2 anticlinal zone. The analysis was carried out in the Buzovna–Mashtaga, Gala, Turkan, Zira, Janub and Janub-2 structures. To identifying the

In the study area, models characterizing the problems of anticlinal zone were drawn up. The models are constructed by using of Surfer, Paint programs.

III. Discussion

The Buzovna fold is complicated by longitudinal fault through its axes, along which its northern limb slipped down.

Industrial accumulations of oil in the Buzovna-Mashtaga fold were discovered in the IV, V, VIII horizons of the Sabunchi, X horizon of the Balakhani, as well as in the PKC, PKS, KS and PK suites. Gas was obtained in the near-crest part of the southern limb of the Buzovna fold in horizon II of the Sabunchi suite.

The Gala field, located southeast of the Buzovna-Mashtaga fold, is confined to the same name and sharply asymmetrical brachyanticline. The fold is complicated along the Surakhani suite by 12 transverse faults, as a result of which the tectonic blocks have en-echelon position. In general, the fold is complicated by 13 normal faults (Fig. 2).

It is noteworthy that one normal type fault developed from the upper Miocene to the middle of the Sabunchi suite; its fault plane dips in the direction opposite to the dip of the fault planes that complicate the fold from the Balakhani suite to the top of the Apsheron stage inclusive. The latter mainly complicate the arch of the fold. In turn, 5 faults complicate the near-crest part of the northeastern limb of the fold from the upper half of the Sabunchi suite to the surface. The complexity of the fold crest by a network of faults almost exclusively in the upper part of the section indicates the development of tensile stresses there, not favorable to the preservation of more or less significant accumulations of hydrocarbons (see Fig. 2).

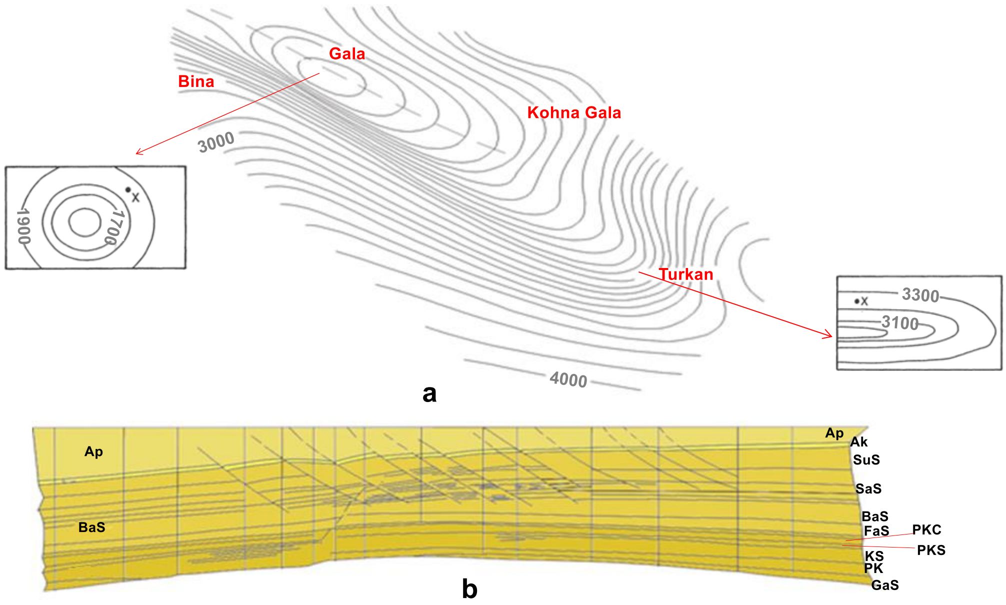

Figure 2: *Gala field: a- structural map along of the roof of the PKC suite; b- geological cross section profile I–I*

In turn, the concentration of hydrocarbon accumulations mainly in the lower section of the Productive series (PS–N $_2{}^1$) is associated with the absence of faults on the crest of the fold, penetrating below the upper half of the Balakhani suite (see Fig. 2). As a result, the lower half of the latter apparently plays the role of a seal for hydrocarbon accumulations in the underlying horizons. The above facts indicate the formation of this fold mainly due to the mechanism of transverse bending [4].

The southeastern periclinal of the fold is strongly elongated along strike due to the development of the Kohna Gala and Turkan structural uplifts in its near-crest zone (see Fig. 2). As a result, the arch of the Gala uplift based on Apsheron deposits is located 3...4 km to the northwest. A characteristic feature of these uplifts is that the dip angles of the layers along the limbs increase with depth. This fact indicates the syndepositional development of the fold. It can be noted that on its southeastern plunge, where the structural uplifts of Kohna Gala and Turkan are located, buried uplifts are developed below the PS, i.e., the fold along the underlying PS deposits is three-arched (see Fig. 2). Structurally, there is a discrepancy between the structure of the upper part of the PS and the structure of its lower section. Another feature of the fold is the complexity of transverse faults, the amplitude of which in the crest of the fold is 50...60 m, closer to the northwestern pericline it decreases to 20...30 m, while on the southeastern plunge to 10...15 m [2]. At the same time, the amplitudes of the faults decrease towards the limbs of the fold and with stratigraphic depth completely attenuate in the upper parts of the Balakhani suite (see Fig. 2, b), which indicates their juvenile age.

The morphology of the Gala uplift changes with depth. Thus, along the roof of the PK suite, the ratio of its width to length is 1:3, while along the Apsheron-Aghjagil deposits it is 1:2. For deposits lying below the PS, the displacement amplitude of faults is 600...700 m, but for the PS it reaches 1200 m [3]. Within the Gala uplift, the main part of the horizons and suites of PS is oil-bearing. In its southeastern pericline there is a structural complication of the Turkan (see Fig. 2), its constituent layers lie at an angle of 5^0. Between the Gala and Turkan areas, the sediments of the Apsheron-Aghjagil stage mainly lie horizontally. Well drilled here

No. 3 (4377 m) showed the presence of oil in the PK suite. Subsequently, wells drilled into this suite No. 1216, 1217 yielded oil only in the second object (GaS_2).

The Zira fold is located southeast of the Turkan structure. Here, the deposits of the upper section of the PS have undergone very weak dislocation, and the lower section manifests itself as a dome-shaped buried uplift. The fold is complicated by two faults with an amplitude of 50 m with a lowered central block (Fig. 3a,b) [2, 3].

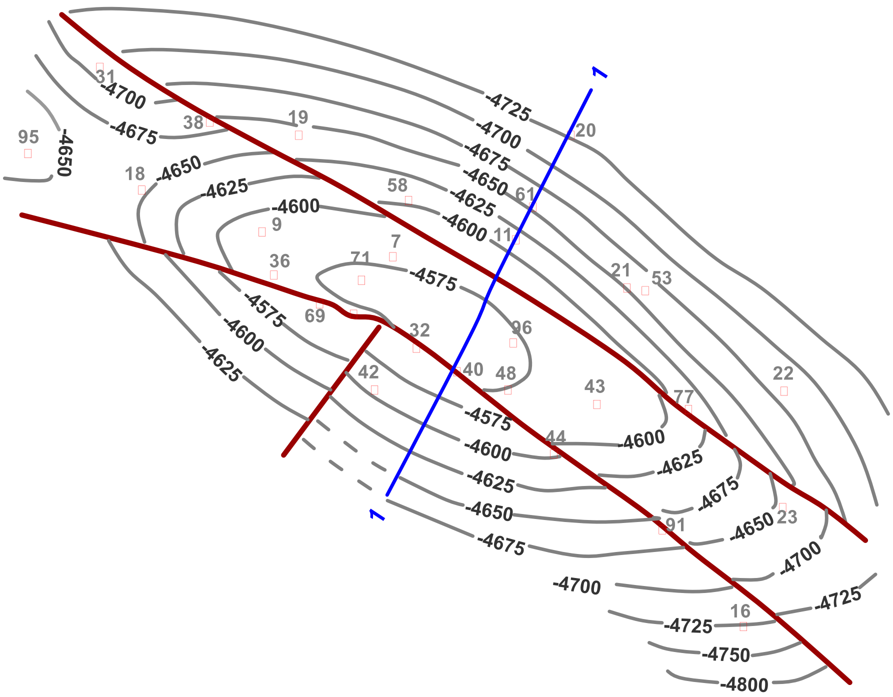

Figure 3a: *Zira field: structural map*

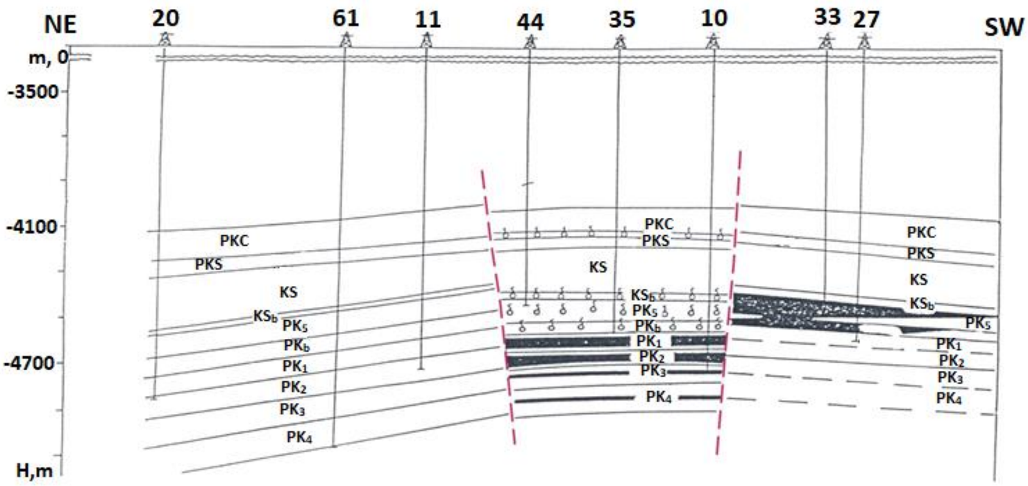

Figure 3b: *Zira field: structural map and geological profile along line I–I*

Based on the profile section, we can say that these fractures played an important role in the distribution of oil and gas over the area and section of the field (see Fig. 3b).

The study of the structures of Zira, Janub, Janub-2 showed that they have a single mode of development and common morphogenetic features. The Zira structure along the top of the PS is also a buried asymmetrical short brachyform fold. Along the roof of the Gala suite, the south limb of the fold lies at an angle of 8...10°, and the north – 3...4°. The Zira field has an oil rim and is gas-condensate-bearing [4].

The Janub structure is a poorly developed buried fold in southeast direction, which flattens upward along the section; as a result, it is very weakly expressed along the top of the Apsheron stage. Along the roof of the Pre-Kirmaki suite, its southwest limb dip at an angle of 6°, and the northeast one – 8° (Fig. 4).

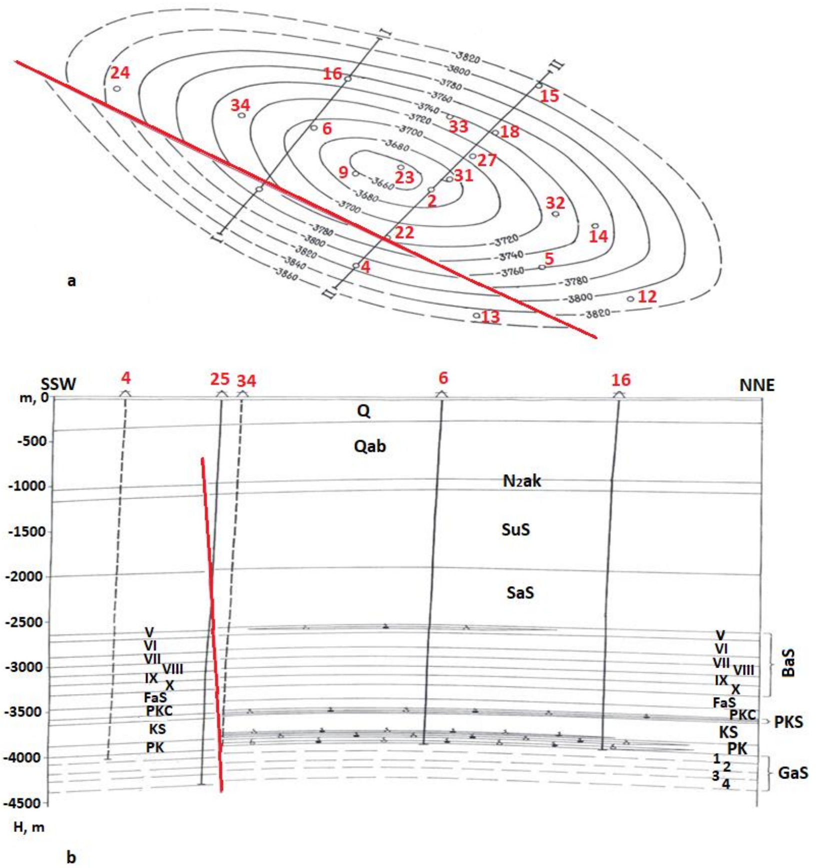

Figure 4: *Janub field: a – structural map by the roof of the PK suite of PS; b –geological cross-section on profile line II–II*

Unlike Zira field, the Janub field in the PS deposits are gas and gas-condensate-bearing.

The Janub-2 fold is located next to southeast of the Janub structure and extends in the same direction. It flattens towards the top of the Aghjagil stage (Fig. 5) and is a gently sloping buried shortened brachyanticline with dimensions of 3.0x1.5 km. With stratigraphic depth, the fold acquires a more distinct form, the dip angles of the limbs increase, and it is more clearly expressed by the bottom of the PS. Based on well data, a transverse fault divides the fold into a downdip northwest and an uplifted southeast blocks. Janub-2 is a gas condensate field, the prospects of which are associated with the lower part of the PS and underlying sediments [4,10].

The Zira, Janub, and Janub-2 uplifts are buried and oil and gas bearing, and are also weakly complicated by disjunctive dislocations, which gives reason to predict the presence of productive objects in the underlying PS strata. The lack complexity with disjunctive dislocations of these folds or its absence also gives reason to predict the likelihood of the formation of gas and gas-condensate accumulations in them.

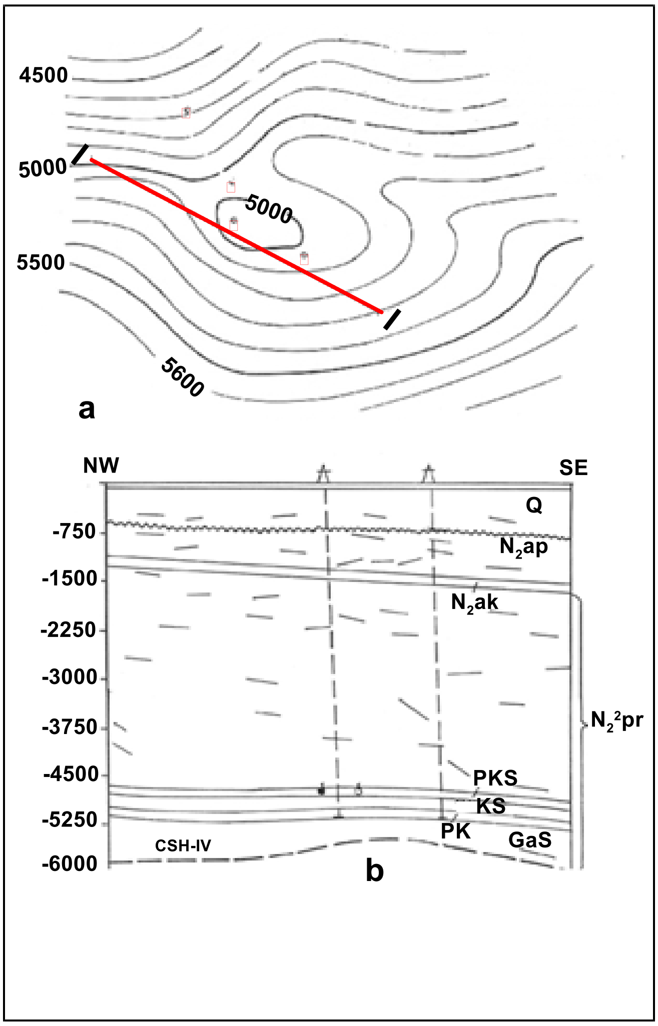

Figure 5: *Janub-2 field: a – structural map by the top of the PK suite of PS; b – seismic geological profile on line I–I*

IV. Results

Thus, it should be noted that along the Buzovna–Mashtaga–Turkan–Janub-2 anticlinal zone, according to the strike of folds from northwest to southeast, as the breakdown of structures by disjunctive dislocations decreases, so phase changes in the accumulation occur. Thus, hydrocarbon accumulations phase changes from oil in the Buzovna-Mashtaga fold to gas condensate and gas phase in the Janub, Janub-2 areas [1].

As can be seen, the degree of complexity of local folds by faults plays a significant role in phase fluid saturation. In this case, regional axis-longitudinal faults can be pathways for the vertical migration of hydrocarbons during the formation of their accumulations or destruction and reformation, and can also serve as a screen on the path of their migration [1].

In other words, any disjunctive can periodically play the role of a screen or conductive. This can also occur in cases where deposits with different hydrodynamic regimes are developed in blocks shielded by a fault. In this case, if a high reservoir pressure gradient occurs between adjacent deposits being developed, it can disrupt the screening role of the fault, which must be taken into account when developing adjacent deposits screened by the same fault.

In the Apsheron oil and gas bearing region, regional axial and transverse disjunctive dislocations play a significant role in the formation, preservation, destruction and reformation of hydrocarbon accumulations. In this area, transverse faults are mostly local and developed mainly in the upper part of the section, and axis-longitudinal faults are mostly regional with deeper penetration and are mostly not components of deep faults. As noted earlier, the Buzovna–Mashtaga field is complicated by 19 transverse and radial faults. Such a large number of them within one fold is obviously associated with upward squeezing of rheologically active clays of the Kovundag-Maykop series (Fig. 6) [2].

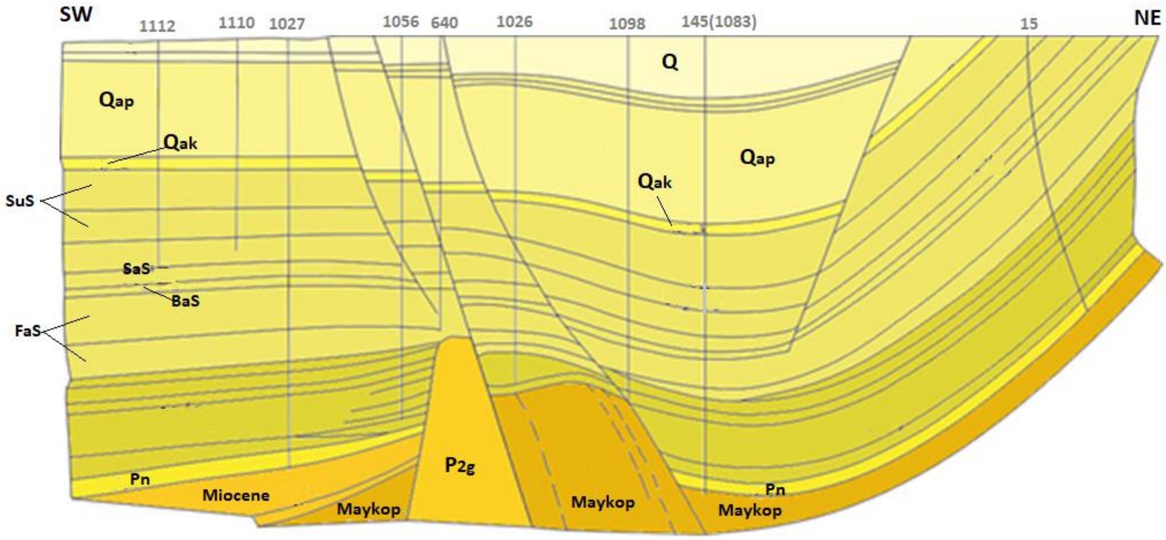

Figure 6: *Geological profile of the Buzovna–Mashtaga field*

As a result, the overlying and more competent rocks of the Pre-Kirmaki, Kirmaki and Post-Kirmaki suites of the lower stage of the PS were subjected to ductile deformations when they were bent and tensile stresses arose in them. The normal faults complicating both limbs of the Buzovna-Mashtaga fold also contributed to the formation of the graben due to the occurrence of tensile stresses. The formation or reformation of hydrocarbon accumulations due to a dense network of normal faults indicates their time-varying role as a conductor and screen, as well as the high probability of the existence of hydrocarbon accumulations in deep-lying rock strata.

From the above, we can conclude that within the territory under consideration, accumulations of hydrocarbons are formed due to stepwise migration. Using the example of the studied anticlinal zone with a chain-like position of local folds and with the main south-southeast–north-northwest direction of fluid migration, i.e., in general along the updip of layers, the differential entrapment of hydrocarbons according to the principle of S.P. Maksimova – V. Gassou is clearly observed [5,7]. Thus, at the southeast end of the zone, in the traps of the Janub, Janub-2 folds, accumulation of gas and gas condensate is found, further along the updip of layers in the Zira fold - gas-gas-condensate-oil, and in the local folds Turkan-Gala-Buzovna-Mashtaga oil deposits were formed (Fig. 7). The presence of gas accumulations in the Aghjagil and Apsheron stages of the Gala and Buzovna-Mashtaga fields may be of a technogenic nature.

The Apsheron oil and gas region is characterized by the destruction and reformation of oil and gas deposits due to the complication of folds by a network of faults and mud volcanism. In the Apsheron, Lower Kura, Shemakhi-Gobustan oil and gas bearing regions, in most cases, mud volcanoes, complicating local uplifts, are located in the zones of intersection of regional axial-longitudinal faults with transverse ones [9]. However, the absence of mud volcanoes in local fold of the Buzovna–Mashtaga–Zira–Janub-2 anticlinal zone is obviously associated with insufficient energy of rheologically active clays of the sedimentary section due to their low mass and absence or very weak development of compressive stresses here. Thus, within the considered anticlinal zone, the Kovundag-Maykop series with a total thickness of about 500...600 m is lithologically represented by clays and shales. An equally important reason for the underdevelopment of local folds in the anticlinal zone under consideration, i.e., their buried nature, is associated with the absence of compressive stresses within this territory [8]. For example, within the Apsheron-Balkan structural megasaddle, complicated mainly by elongated brachy- and linear folds, as well as different-scale and different-type disjunctives, including transverse strike-slip faults, mud volcanism is widely developed. The nature of the latter is associated with the subduction nature of the structural megasaddle.

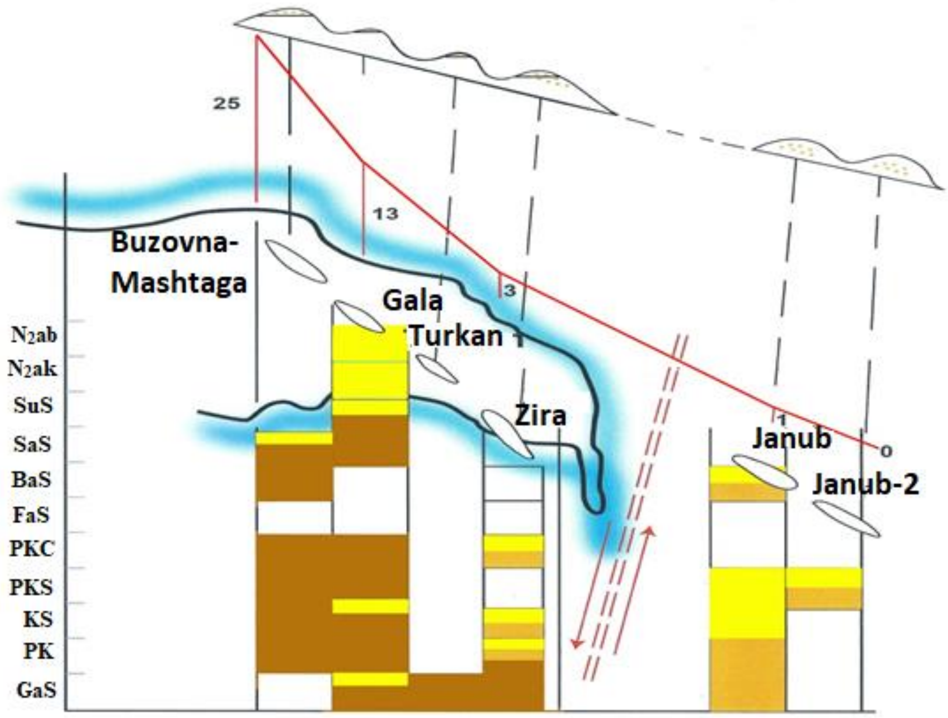

Figure 7: *The nature of oil and gas saturation and the level of dislocation of local folds of the anticlinal zone Buzovna–Mashtaga–Zira–Janub-2*

V. Conclusions

1. Buried folds Janub, Janub-2, according to morphogenetic, structural-tectonic characteristics, spatial orientation and nature of oil and gas saturation, are a structural-tectonic continuation of the Buzovna–Mashtaga–Turkan–Zira anticlinal zone, which developed mainly due to the cross-buckle mechanism.
2. The level of dislocation of local folds of the Buzovna–Mashtaga–Turkan–Janub-2 anticlinal zone weakens in the southeast direction due to distance from the Greater Caucasus collision.
3. Buried local uplifts of the studied anticline zone, expressed as hemianticlines in the overlying rock strata, are promising for oil and gas.
4. Fluid saturation of the reservoirs of natural traps of the studied anticlinal zone occurred according to the principle of differential trapping clearly expressed here by S.P. Maksimova – V. Gassou in the direction of the regional updip of layers and depending on the level of their complexity with disjunctive dislocations.

THE ROLE OF DIGITAL PERSONALITY IN PROMOTING SUSTAINABLE BEHAVIOR

Natalia Alexandrova[1] Elena Arbuzova[2]

•

Dostoevsky Omsk State University, RUSSIA
natalie_v_al@inbox.ru

Abstract

In the context of rapid technological advancement and global environmental challenges, digital identity emerges as a crucial tool for promoting sustainable behavior. Digital identity refers to the way individuals express themselves and interact within the online space, influencing their actions and choices in the real world. This paper explores various aspects of digital identity, including its impact on the formation of sustainable habits and practices, the enhancement of environmental awareness, and the development of social responsibility. It analyzes how social media platforms and digital technologies can be utilized to create communities that foster the exchange of sustainable practices and ideas. Additionally, the challenges related to data security and privacy that may affect the use of digital identity in achieving environmental goals are discussed. In conclusion, the necessity of integrating digital identity into strategies for promoting sustainable behavior is emphasized, as it can contribute to a more conscious and responsible relationship with the environment.

Keywords: digital identity, sustainable behavior, environmental awareness, social media, technology, social responsibility, data protection, privacy, sustainable practices

I. Introduction

In an era defined by rapid technological advancement and escalating environmental challenges, the urgency to promote sustainable behavior has become paramount. The world faces a myriad of pressing issues, including climate change, resource depletion, pollution, and biodiversity loss. These challenges necessitate innovative and effective approaches to inspire individuals and communities to adopt more sustainable practices. One promising avenue is the integration of digital identity into sustainability efforts. As societies become increasingly digitized, understanding how digital identity can shape behaviors and attitudes toward the environment is essential.

Digital identity refers to the online persona that individuals cultivate through their interactions on various digital platforms, including social media, forums, and other online communities. This identity encompasses not only personal information but also the values, beliefs, and behaviors individuals express in the digital realm. With the advent of social networks and online communication, people are no longer passive consumers of information; they actively engage, share, and influence one another's behaviors. This engagement provides fertile ground for promoting sustainable practices, as individuals can leverage their digital identities to advocate for environmental issues and inspire change.

Digital identity can significantly impact sustainable behavior in several ways. First, it influences how individuals perceive themselves in relation to sustainability. When people align their digital identity with eco-friendly values—such as reducing waste, conserving energy, and supporting local businesses—they are more likely to adopt these behaviors in real life. For instance, individuals who showcase their sustainable practices online may feel a heightened sense of accountability to continue these actions, as their peers reinforce these behaviors through likes, shares, and comments.

Additionally, digital identity fosters community building around shared sustainability goals. Online platforms enable individuals to connect with like-minded people, forming communities that support and encourage sustainable practices. These communities can facilitate the exchange of ideas, resources, and information about sustainable living, creating a sense of belonging that motivates individuals to engage in environmentally friendly behaviors. As these digital communities grow, they can amplify their collective influence, driving broader societal change.

Another critical aspect of digital identity's role in promoting sustainable behavior is its capacity to raise awareness about environmental issues. Digital platforms serve as powerful channels for disseminating information about sustainability, from climate science to local conservation efforts. Influencers, activists, and organizations can use their digital identities to share compelling narratives, engage followers, and mobilize action. This can include campaigns to reduce plastic use, promote renewable energy, or support wildlife conservation initiatives.

Moreover, digital identity enables the sharing of educational resources, helping individuals understand the impact of their choices on the environment. Online tutorials, webinars, and interactive content can provide valuable insights into sustainable practices, making it easier for individuals to incorporate eco-friendly habits into their daily lives. By harnessing the power of digital identity, individuals can become informed advocates for sustainability, influencing others and contributing to a larger movement toward environmental responsibility.

Despite its potential, the integration of digital identity into sustainability initiatives is not without challenges. Privacy concerns are paramount, as individuals may hesitate to share personal information or engage in online discussions about their eco-friendly choices due to fears of data misuse or surveillance. The need for robust data protection measures is essential to ensure that individuals feel safe in expressing their digital identities.

Furthermore, the phenomenon of "greenwashing" poses a significant challenge. As businesses and organizations increasingly adopt sustainability messaging, discerning authentic commitments from superficial marketing tactics can be difficult for consumers. Digital identity can inadvertently contribute to this issue, as individuals may align their online personas with sustainable practices that do not reflect their real-world behaviors. This disconnect can undermine the credibility of sustainability efforts and diminish trust in digital advocacy.

II. Methods

To explore the role of digital identity in promoting sustainable behavior, three distinct methods were employed: survey analysis, interviews and focus groups, and case study analysis. Each method contributed unique insights into the relationship between digital identity and sustainable practices.

1. Survey Analysis

A comprehensive survey was distributed across various demographic groups to gather quantitative data. The survey included questions on digital identity usage (e.g., social media, digital platforms) and sustainable behaviors (e.g., recycling, energy conservation, ethical consumption). Respondents were asked about:

How often they engaged with digital platforms that focus on sustainability.

Whether their online identity influenced their real-world sustainable actions.

Perceived barriers to adopting eco-friendly behaviors through digital means.

Analysis: The data was statistically analyzed to find correlations between digital engagement and sustainable behavior, using regression models and cross-tabulation to identify trends across different age groups, education levels, and regions.

2. Interviews and Focus Groups

Semi-structured interviews and focus group discussions were conducted with key participants, including sustainability advocates, environmental researchers, and digital platform developers. These qualitative methods provided a deeper understanding of:

Personal experiences with how digital identity influences their commitment to sustainable practices.

Motivations for engaging in online sustainability communities and how digital identities shape those motivations.

Challenges and opportunities faced in promoting eco-consciousness through digital identities.

Analysis: Thematic analysis was employed to identify common themes such as social accountability, digital peer influence, and the impact of digital rewards systems on promoting environmentally responsible behavior.

3. Case Study Analysis

Several case studies of digital platforms that successfully promote sustainability (e.g., apps or websites dedicated to green living, carbon footprint tracking, or ethical shopping) were analyzed. The focus was on:

How these platforms construct and maintain user digital identities that align with environmental values.

The mechanisms used to encourage sustainable actions, such as gamification, social sharing, or incentives.

The long-term impact of these platforms on user behavior and environmental outcomes.

Analysis: Comparative analysis was conducted across case studies to evaluate which strategies most effectively integrate digital identity with sustainable behavior. Specific factors such as user engagement levels and measurable environmental impact were compared.

By combining these three methods, the study offers a comprehensive understanding of how digital identity can drive sustainable behavior and what strategies can further enhance this connection.

III. Results

Although discussions on sustainability and its relevance began to surface prominently towards the end of the last century, particularly with the 1972 Stockholm Conference organized by the United Nations (UN) (Rodrigues, 2009), concerns regarding this issue actually date back to the first (1760-1840) and second (1850-1945) industrial revolutions. The industrial revolution led to a dramatic increase in the production of goods and wealth, raising people's purchasing power. However, it also resulted in negative outcomes, including increased economic inequalities and significant environmental impacts due to heightened production. During this time, economists like John Stuart Mill (1848) and Thomas Malthus (1878) warned of the adverse effects that unchecked economic and population growth could have on both the environment and human well-being. Furthermore, the industrial revolution introduced a surge in consumption, making it a central aspect of economic development and shaping human relations. Mass production created an environment where consumerism—driven by the need to quickly dispose of goods—became normalized and encouraged. Over time, the satisfaction of personal desires began to take precedence over the fulfillment of genuine needs. This "consumerism," the ever-increasing production and acquisition of non-essential goods in pursuit of well-being, has since become a critical consideration within the sustainability discourse, as it places tremendous pressure on natural resources and the environment. Growing concerns over long-term environmental degradation sparked global events and environmental movements in the late 1960s and 1970s, which initiated widespread debates on the limits of growth and how environmental issues could be integrated into mainstream development goals. One significant milestone in this sustainability debate was the UN World Commission on Environment and Development's (WCED) 1987 "Our Common Future" report. It was one of the first comprehensive efforts to establish a global agenda for rethinking the human development model. The report defined sustainable development as development that "meets the needs of the present without compromising the ability of future generations to meet their own needs". It highlighted poverty in developing nations and rampant consumerism in developed countries as key factors preventing equitable development and causing serious environmental crises, which in turn sparked extensive academic and political discussions worldwide. This evolving sustainability discourse eventually found its way into business practices, with the introduction of the "Triple Bottom Line" concept. This framework expanded corporate objectives beyond just economic factors, proposing that sustainability involves the pursuit of economic prosperity, environmental protection, and social equity in an interconnected manner. In environmental terms, this approach urged businesses to preserve natural capital and maintain the planet's life support systems by balancing resource generation, consumption, and waste management.

IV. Discussion

Scientific and academic advancements in sustainability, alongside technological innovations and the rise of an eco-friendly culture, have fostered an environment where brands are increasingly motivated to address environmental issues and contribute to their resolution. Consequently, numerous online brand campaigns have emerged, wherein companies raise awareness about environmental challenges and strive to encourage sustainable behaviors among consumers. Many brands are now implementing pro-environmental initiatives, such as creating digital re-commerce platforms that promote conscious consumption.

However, while some brands successfully influence consumers' pro-sustainability behaviors through these actions, others fall into the trap of greenwashing, which can have detrimental effects not only on the brands themselves but also on consumers’ willingness to engage in environmentally friendly practices. To ensure the success of their online environmental campaigns and effectively inspire pro-sustainability in their consumers, brands must establish a well-defined and authentic environmental purpose. This means aligning their communications with their actual practices to avoid inconsistencies. Specifically, brands must ensure that their environmental stance is congruent with their corporate identity, values, business operations, and overall mission. Additionally, brands must engage authentically and actively with the causes they advocate.

Lin emphasizes that companies should invest their resources and expertise in areas where they possess knowledge and a competitive advantage. They should also ensure that their internal policies align with the environmental purpose they wish to project in their campaigns. Collaborating with activists is crucial for understanding and fulfilling their collective moral responsibilities toward communities and the environment.

For brands to effect meaningful changes in consumers' pro-sustainable behavior, their environmental positions must be perceived as genuine and sincere. Authentic environmental activism requires maintaining a continuous alignment between a brand's stated intentions—reflected in its communication messages—and the actions it takes, such as implementing pro-environmental corporate practices, forming partnerships with environmental organizations, and supporting environmental initiatives.

Beyond establishing a coherent environmental purpose and maintaining authenticity, companies must communicate their environmental stances and actions effectively to ensure they resonate with the target audience and catalyze positive environmental changes. According to Key et al. (2021) and Taylor et al. (2001), brand activist communications should prioritize dialogic communication, facilitating ongoing interactions and providing relevant information to the target audience. Companies must understand how their audience receives and interprets their messaging, creating campaigns that align with consumers' expectations, experiences, and comprehension of the environmental issues at hand.

To encourage consumers to adopt pro-sustainable behaviors and commit to conscious consumption, brands should not only inform consumers about their environmental policies and the importance of the advocated environmental issues but also educate them on how to act and consume more sustainably. This could involve providing guidance on the responsible use and disposal of products. Additionally, brands must consistently convey their perspective across all online and offline communications, capturing and reinforcing the essence of their environmental stance with transparency and credibility. This includes highlighting their environmental strengths while also acknowledging areas for improvement.

In summary, companies need to be intentional in communicating their environmental positions and causes, grounding their messages in tangible evidence of their environmental performance. This could include third-party audits or ecolabels to reduce the risk of consumer alienation and enhance their capacity to drive pro-environmental behaviors. Given the significance of environmental communication within the realm of new digital platforms, particularly in market contexts, further investigation into how these platforms can facilitate or hinder pro-environmental change is essential. Future research could explore how brands' online environmental communication strategies impact various stakeholders, including employees and shareholders, analyze consumer reactions to greenwashing on social media, and examine whether such campaigns hinder conscious consumption by fostering skepticism. Additionally, studying how brands can make environmental issues more appealing to consumers through immersive technologies like augmented and virtual reality could prove valuable. Internally, it would be insightful to investigate how brands leverage digital technologies to reduce their ecological footprints, for instance, by enhancing internal communication regarding sustainability, improving supplier product breakage management, or optimizing distribution routes.

Abstract

Based on an analysis of the capabilities of various software systems for analyzing the modes of distribution power networks using simulation models, it was determined that the most effective module that allows for visual and operational research is the use of the DIgSILENT PowerFactory program. Using this complex, a study of the load conditions of the Sarygaya distribution network of Azerishik OJSC was carried out. The results obtained showed that the loads of most 6 kV feeders exceed the permissible values, the voltage drops are high, and these conditions confirm the high probability of emergency outages in the network. Accordingly, proposals were made to redesign and design the network topology. The calculated experiments conducted with the application of the software complex require the implementation of the necessary scheme-mode measures for the improvement of the reliability of the distribution network and the implementation of uninterrupted electric power supply. As one of such measures, it was proposed to connect green energy sources to two points of the studied distribution network. Studies have confirmed that the obtained new circuit topology is convenient and effective.

Keywords: distribution network, DIgSILENT PowerFactory complex, line overloads, voltage drop, voltage profile

I. Introduction

The application of green energy technologies through renewable sources is a priority for modern energy systems. These sources are primarily integrated into distributive electric systems (DES) at lower voltage levels [1-4]. However, addressing the challenges of modern demands involves improving or reconstructing existing distributive networks and employing various approaches to solve emerging issues. Primarily, adopting effective decisions among existing and proposed alternatives requires rigorous regime investigations. Conducting regime investigations through simulation models is advantageous [5]. These models simulate the processes of electricity generation, transmission, and distribution in the power system, enabling the analysis of system performance mechanisms. Such analyses typically aim to identify important regime parameters such as voltage drops, active and reactive power losses, non-sinusoidal and non-symmetrical regimes, and power distribution to assess the overall state of the energy system.

One of the main issues addressed by DES is assisting in optimizing system design. Simulations are conducted to improve the system's performance mechanism and increase efficiency by altering different components and parameters. This is crucial for reducing investment costs, minimizing power losses, and ensuring security. Furthermore, simulation models in DES allow for the optimization of exploitation processes, such as energy production and transmission, in the most effective and secure manner, empowering system and network operators to manage them in real time through simulations.

Moreover, in complexly configured DES, simulations can be used to determine the type of fault and implement necessary corrections, analyze and resolve issues such as energy imbalance, regime oscillations, non-sinusoidal voltage problems, voltage drops, and other problems. Simulations can also be employed for the analysis and resolution of these issues[6,7]. The article focuses on the analysis of regimes and the enhancement of efficiency based on real DES using DIgSILENT PowerFactory complex models, in conjunction with the application of green energy technologies.

II. Mathematical Model for the Regime Calculation of the Distributive Network

Generally, the following non-linear equations system is used in the investigation of regimes in electric power systems: [8]:

$$\left.\begin{aligned}\Delta P\left(\delta,\ P_s,\left|U_{наг}\right|,\ Q_g\right)=P_i^{sp}-\left|U_i\right|\cdot\sum_{j=1}^{N}\left|U_j\right|\cdot\left(G_{ij}\cos\delta_{ij}+B_{ij}\sin\delta_{ij}\right)=0,\ \ \forall i\in N\\ \Delta Q\left(\delta,\ P_s,\left|U_{наг}\right|,\ Q_g\right)=Q_i^{sp}-\left|U_i\right|\cdot\sum_{j=1}^{N}\left|U_j\right|\cdot\left(G_{ij}\sin\delta_{ij}-B_{ij}\cos\delta_{ij}\right)=0,\ \forall i\in n_{pa}\end{aligned}\right\}\qquad(1)$$

in here $\Delta P, \Delta Q$ - the non-linear difference functions of active and reactive power injections in the $i -$ node; P_i^{sp}, Q_i^{sp} the given values of active and reactive power injections at the $i -$ node; $\delta -$ the angle of the voltage vector at the node; $P_s -$ the generation active power of the base node; $Q_g - PU$ the generation reactive power; $|U_{наг}| - PQ$ the voltage at the nodes; $|U_i| -$ the voltage at the
$i -$ node; $\delta_{ij} -$ The angle between the voltage vectors of busbars i and j ; $G_{ij}, B_{ij} -$ the real and imaginary parts of the admittance matrix elements; $N -$ the number of nodes.

Equations (1) and (2) can be written in vector form as follows:

$$f(x)=\begin{bmatrix}\Delta P\left(\delta,P_s U_{PQ},Q_g\right)\\ \Delta Q\left(\delta,P_s,U_{PQ},Q_g\right)\end{bmatrix}=0\qquad(2)$$

Since it is directly impossible to obtain several solutions simultaneously based on equation (3), the problem is solved iteratively with the help of known methods. For example, by using the Newton-Raphson method, the problem posed by the linearization of equations (1) and (2) can be solved:

$$\begin{bmatrix}\Delta P\\ \Delta Q\end{bmatrix}=\left[J\right]\begin{bmatrix}\Delta\delta\\ \Delta P_s\\ \Delta U_{PQ}\\ \Delta Q_g\end{bmatrix}\qquad(3)$$

here $[J]-$ As known, the Jacobian matrix is written as follows [10,11]:

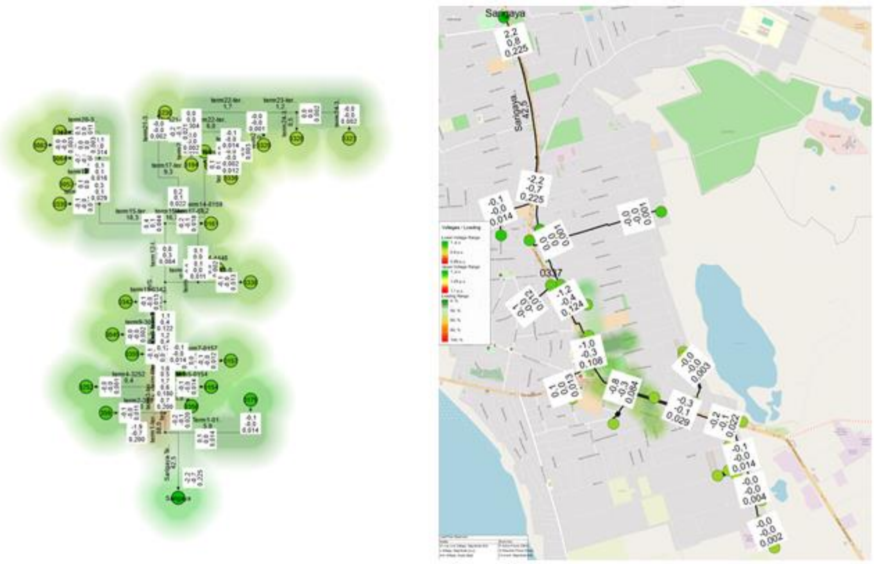
$$[J] = \begin{bmatrix} \frac{\partial P}{\partial \delta} & \frac{\partial P}{\partial P_s} & \frac{\partial P}{\partial U_{PQ}} & \frac{\partial P}{\partial Q_g} \\ \frac{\partial Q}{\partial \delta} & \frac{\partial Q}{\partial P_s} & \frac{\partial Q}{\partial U_{PQ}} & \frac{\partial Q}{\partial Q_g} \end{bmatrix} \quad (4)$$

III. Investigation of the Determined Regimes of the Distributive Network

III.1. Research on the current determined regime of the power grid

Currently, the problems identified in the network of the transmission system operator of the electricity system in Azerbaijan have not yet been fully resolved. These problems include inadequate planning for the construction of new substations and half-stations, excessive voltage drop, continued use of outdated electrical equipment, etc. To address these issues, it is crucial to simulate replacement equipment and establish a mathematical model during the refurbishment process. For instance, analyses of load and voltage profiles have been conducted using the "DIgSILENT Powerfactory" program for the 6 kV feeder "Novxanı - 1 H/X," which is 11.2 km long and supplied from the 35/6 kV "Sarıqaya" substation. Active and reactive power losses have been calculated, and simulations have been performed for refurbishment works on the feeder. Several loading regimes have been examined in the simulation program: normal regime, 50%, and 70% overload regimes.

In Figure 1, the simulation model (a) of the load analysis of the Novxanı-1 6 kV feeder and the integration scheme (b) of the feeder into the GIS are presented. As shown in Figure 1a, there are several branches along the length of the distribution network, and the 6/0.4 kV voltage transformer stations are capable of handling underloading conditions (up to 10%). Even in normal loading conditions, some elements may experience overload (Figure 1b), highlighting the necessity of appropriate exploitation, refurbishment, and improvement measures to enhance the efficiency of the network operation. Research investigations on the aforementioned issues were conducted based on the simulation model of the Distribution Management System (DMS). Initially, the loading of the 17-branch 6 kV feeder was examined under the current normal operating conditions. Table 1 illustrates the voltage profile on the "Novxanı-1 6 kV feeder line" within the network area connected to "Sarıqaya" in the normal regime.



a) b)

Figure 1: *Simulation model of the 6 kV "Novxanı-1" feeder: a - model of the load analysis in the determined regime of the feeder; b - integration of the load analysis mathematical model into the Geographic Information System (GIS) in the determined regime of the feeder.*

. In the current determined operating regime, there has been a voltage drop of ΔU=7% at the final transformer station of the feeder.

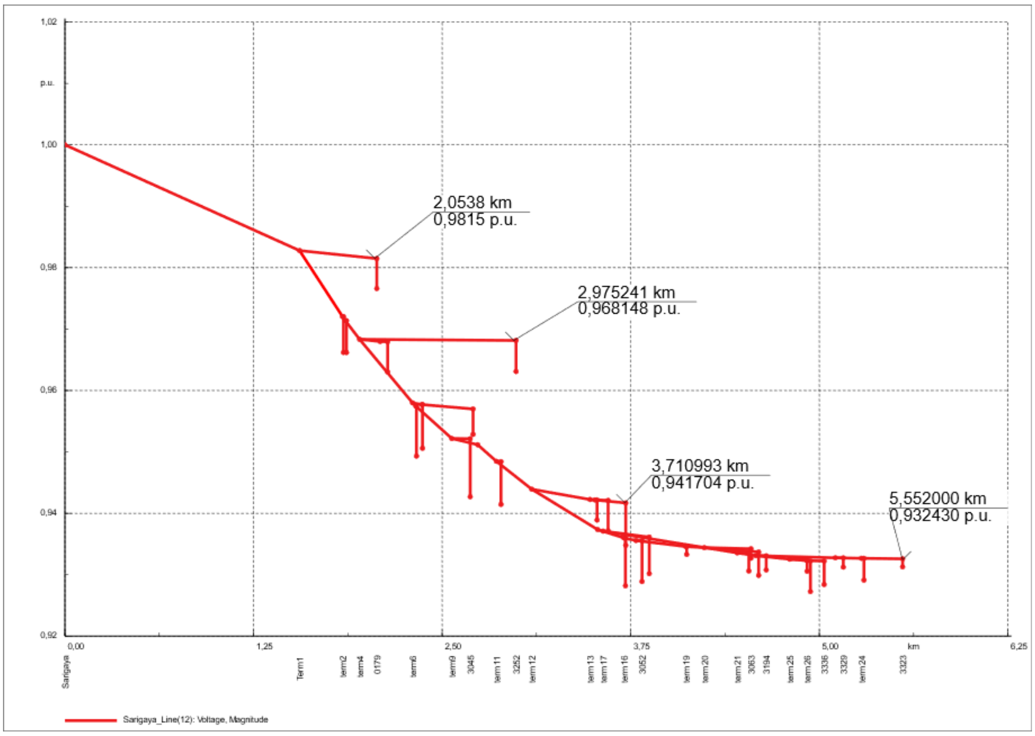


Figure 2: *Voltage profile along the Novxanı-1 feeder line in the current determined operating regime*

Let's examine the loadings on the 6 kV feeder lines (Table 1). As shown, the loadings of individual branches vary within the 23-88% interval. For instance, the load on the term9-term10 branch is minimal at 23%, while the term1-term2 branch is at 88%. In other words, the loadings vary along the length of the feeder, resulting in a wide range of voltage drops. As a result, voltage levels at demand nodes fluctuate between (0.932-0.942)·U_nom, which is below the nominal level.

Table 1: *Loading Degrees of Sarıqaya Distribution Network Feeder Lines*

Name	Network	Loading, %	Current value, kA
term1-term2	Sariqaya	88,0	0,211
term2-term3	Sariqaya	83,4	0,200
term3-term4	Sariqaya	75,1	0,180
Bəzi term4-term6	Sariqaya	68,7	0,165
term6-term8	Sariqaya	58,1	0,139
term8-term9	Sariqaya	51,5	0,124
term10-term11	Sariqaya	50,8	0,122
term11-term12	Sariqaya	45,2	0,108
Sarigaya-Term1	Sariqaya	42,5	0,225
term12-term15	Sariqaya	35,0	0,084
term9-term10	Sariqaya	23,0	0,122

Looking at the current loading regime of the feeder, we see that between two branches, the AS-50 line is loaded up to 88% of its nominal capacity in the determined regime. It has been determined that in some nodes, the reactive/active ratios (reactive power factor) fall within the interval of 0.35 – 0.365. The high demand for reactive power leads to significant power and voltage losses, rendering the regime inefficient. Specifically, an active power loss of 106 kW and a reactive power loss of 259 kVAr are considered.

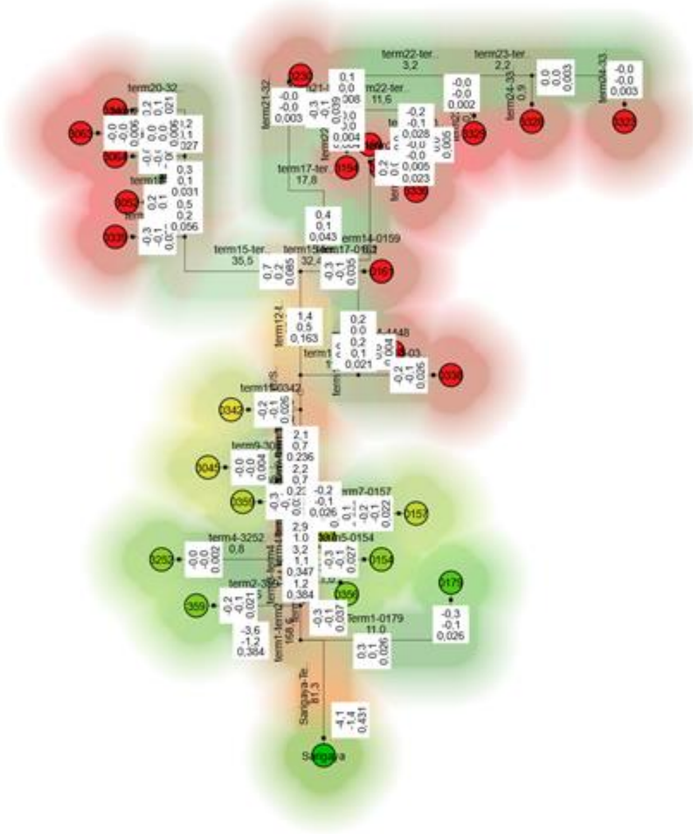
III.2. Simulation Study of Overloading Regime

If we consider a democratic increment, it is anticipated that the loading of the Distribution Management System (DMS) will increase by 50% compared to the current situation. Therefore, a simulation of the feeder's 50% overload regime has been conducted (Figure 3). It is evident from Figure 3 that the probabilities of overload for the branches of the 6 kV feeder line in the distribution network are significantly high (Figure 3a), and the values of voltage drops exceed the permissible limit at 17 nodes (Figure 3b), in other words, they are greater than 11%. In this regime, we can observe an increase in voltage drop at the final node supplied by the feeder by up to 13%.

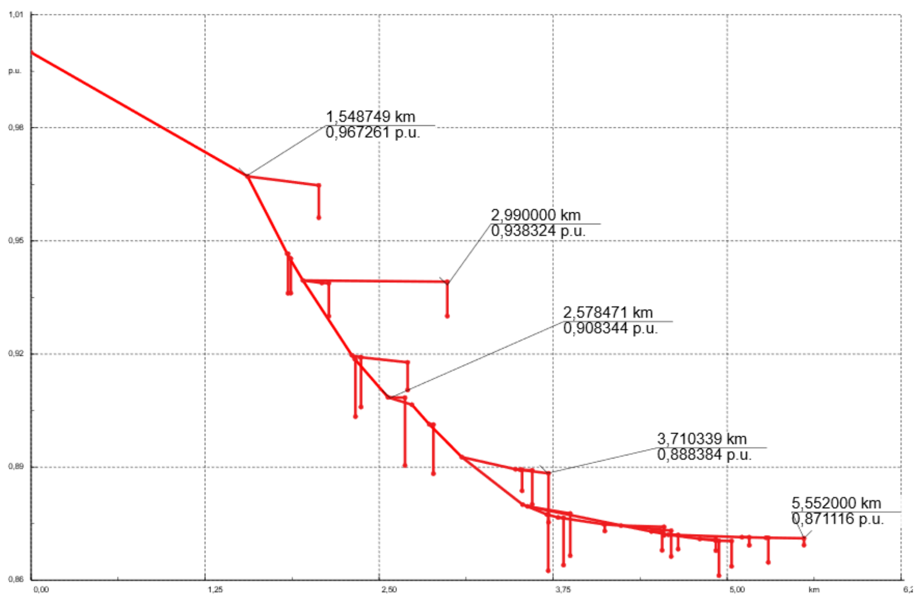
An air line with a nominal value of 240 A being overloaded by more than 68.6% above its nominal value would not only affect the quality of electrical energy but also lead to interruptions and accidents in electricity supply. This is primarily related to the inadequate width and length of the feeders, necessitating appropriate measures to modernize the network.

As shown in Table 2, some branch lines are exposed to overloading beyond their nominal capacity (12.3-68.6%). For instance, an air line with a nominal value of 240 A being overloaded by more than 68.6% above its nominal value could lead to both a decrease in the quality of electrical energy and interruptions or accidents in electricity supply. In Figure 4, the active and reactive demands of consumer nodes are depicted under a 50% overload condition.

As observed, during a 50% overload, the reactive/active ratios (reactive power factor) of the consumer nodes in the distribution network fall within the range of 0.35 – 0.365. In this scenario, the demand for reactive power is high, resulting in significant power (active power loss of 366 kW, reactive power loss of 550 kVAr) and voltage losses (13.4%) in the network, rendering the regime inefficient.



a)



b)

Figure 3. *Overloads of distribution network feeder lines*
a – Loads of feeder lines; b - distance dependence profile of feeder voltages

As seen, the voltage values fluctuate within the range of (0,876-0,915)U_{nom} , and they are significantly below the nominal level.

Table 2: *The loading of the feeder and its branches*

Name	Network	Real Loading, %	Real Loading, kA
term1-term2	Sariqaya	168,6	0,405
term2-term3	Sariqaya	160,0	0,384
term3-term4	Sariqaya	144,5	0,347
term4-term6	Sariqaya	132,5	0,318
term6-term8	Sariqaya	112,3	0,269
term8-term9	Sariqaya	99,7	0,239
term10-term11	Sariqaya	98,2	0,236
term11-term12	Sariqaya	87,5	0,210
Sarigaya-Term1	Sariqaya	81,3	0,431
term12-term15	Sariqaya	67,8	0,163
term9-term10	Sariqaya	44,5	0,236
term15-term16	Sariqaya	35,5	0,085

III.3. Efficiency of the distribution network with the application of green energy technologies promotion

Another method of increasing the operational efficiency of the viewed grid is the application of green energy technologies based on wind and solar energy sources. Since the Absheron region is rich in wind and solar reserves, the connection and integration of these sources should be considered in the modernization of the grid. For instance, given that the average wind speed on the Absheron Peninsula is 9.1 m/s and the solar irradiance density per square meter is 3.7 kWh/m^2, the advantage of utilizing green technologies according to the existing scheme is already known. However, it is necessary to conduct regime investigations and confirm the profitability of the measures taken. For this purpose, research was conducted using the DIgSILENT PowerFactory complex and the simulation model established by PEŞ.

Figure 4 illustrates the simulation model of integrating green technologies (one solar and one wind power station) into the distribution grid. As shown in the figure, a solar station with a capacity of 2 MW is connected to the 6 kV section of the Sarıqaya node, while a wind station consisting of 2 Furhlender FL 2500 wind turbines with a total capacity of 5 MW is connected to the 35 kV node. The “TM 0342” branching from “TM 0338” is divided into two sections via the circuit-breaker.

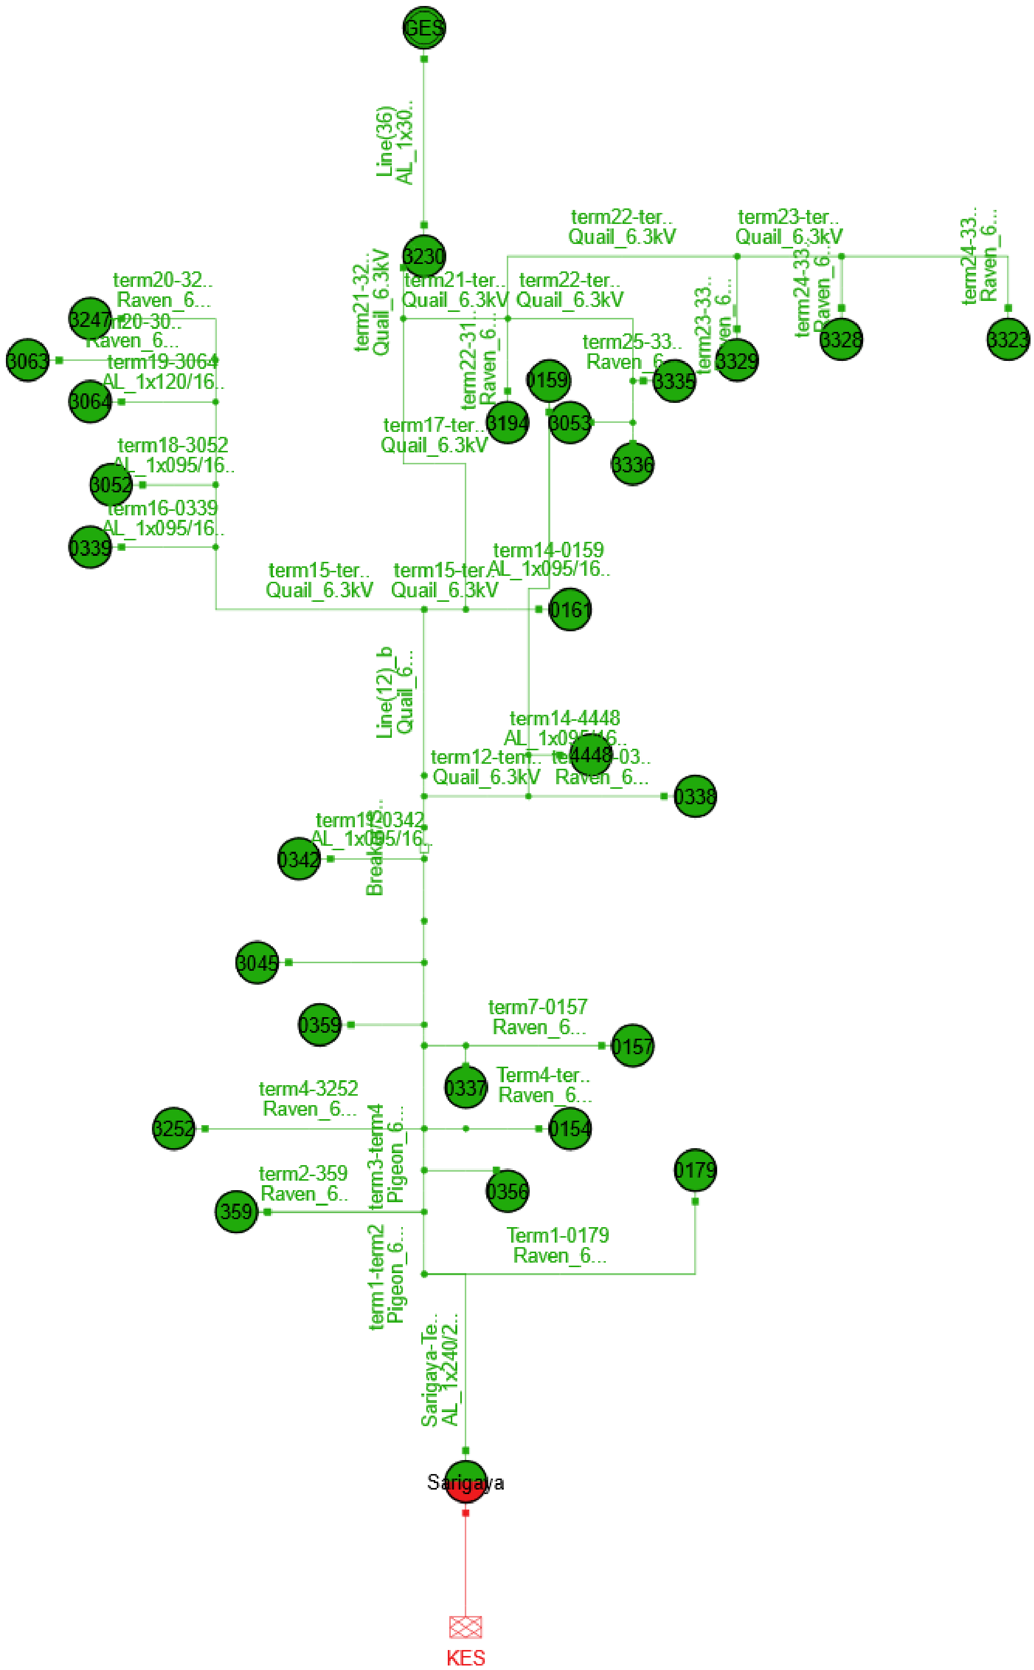


Figure 4: *The model of a distribution network for the current determined regime, integrating green energy sources (wind, solar)*

In Fig.5, the voltage values and profiles of the branches of the 6/0.4 kV distribution network, considering the integration of green energy sources, are provided. As seen from Figure 5, the voltage values on the branches (0,969-1,0)U_{nom} are within the acceptable normal release limits, with a maximum loading of 37%. With the presence of green sources, the analysis of the active and reactive power demands on consumer branches of the distribution network has revealed that the reactive power ratio in the considered regime ranges from 0,112 to 0,465, necessitating appropriate measures for reactive power compensation.

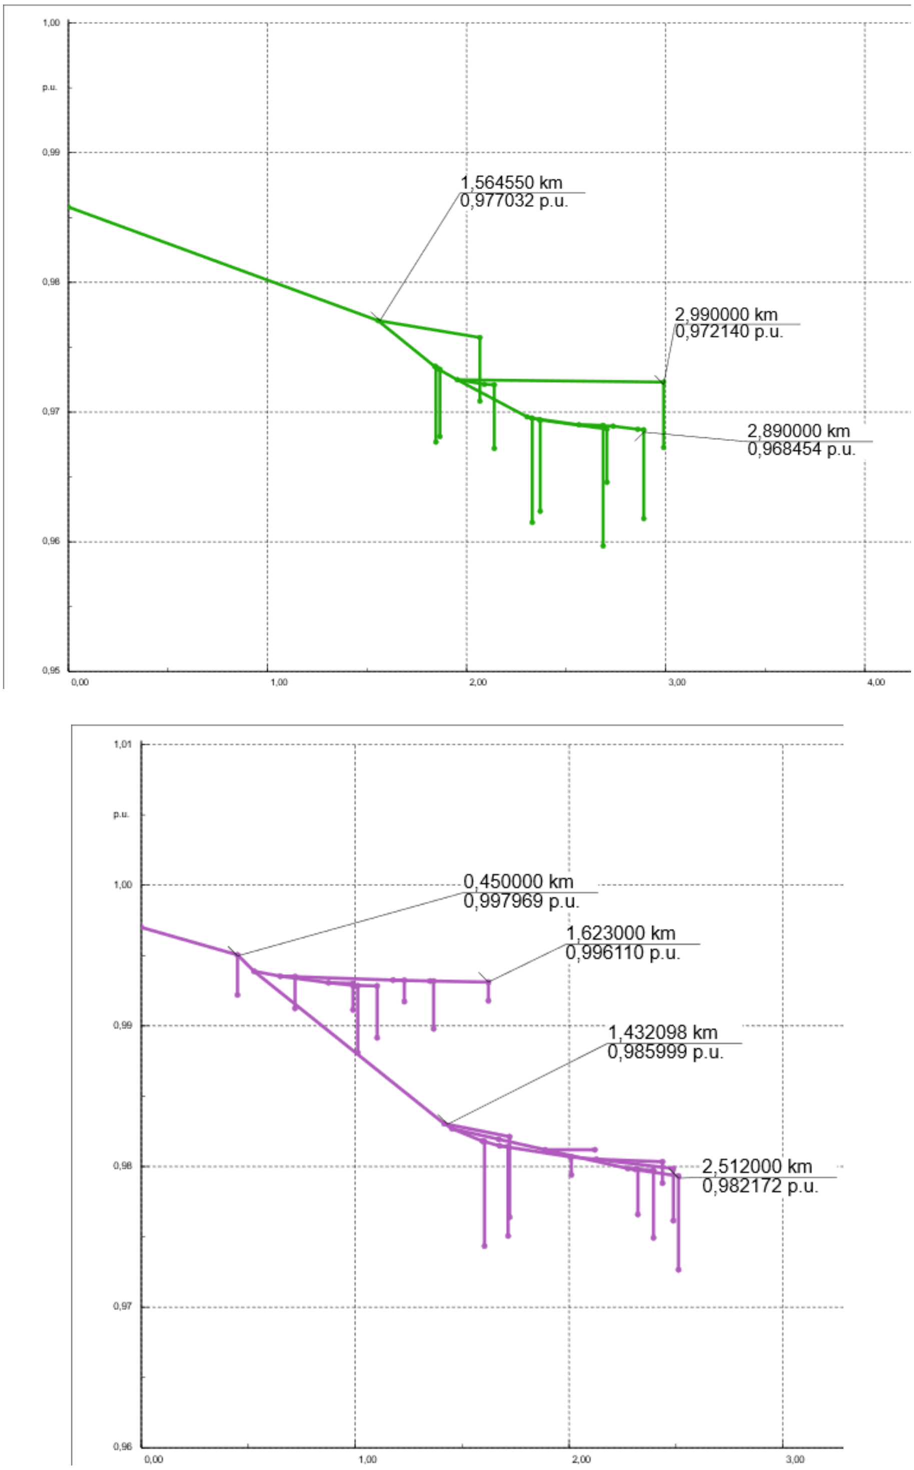

Figure 5: *Voltage profile with the integration of green energy sources*

In Fig. 6, the voltage values and profile for consumer branches are provided for the regime of 50% excess loading with the integration of wind and solar energy sources into the distribution network. As evident from the voltage profile and values, the voltages are within the range of (0,941-1,0)U_{nom} and are considered acceptable. Accordingly, the loading on feeder lines ranges from 13.1% to 67.8% in the considered scenario.

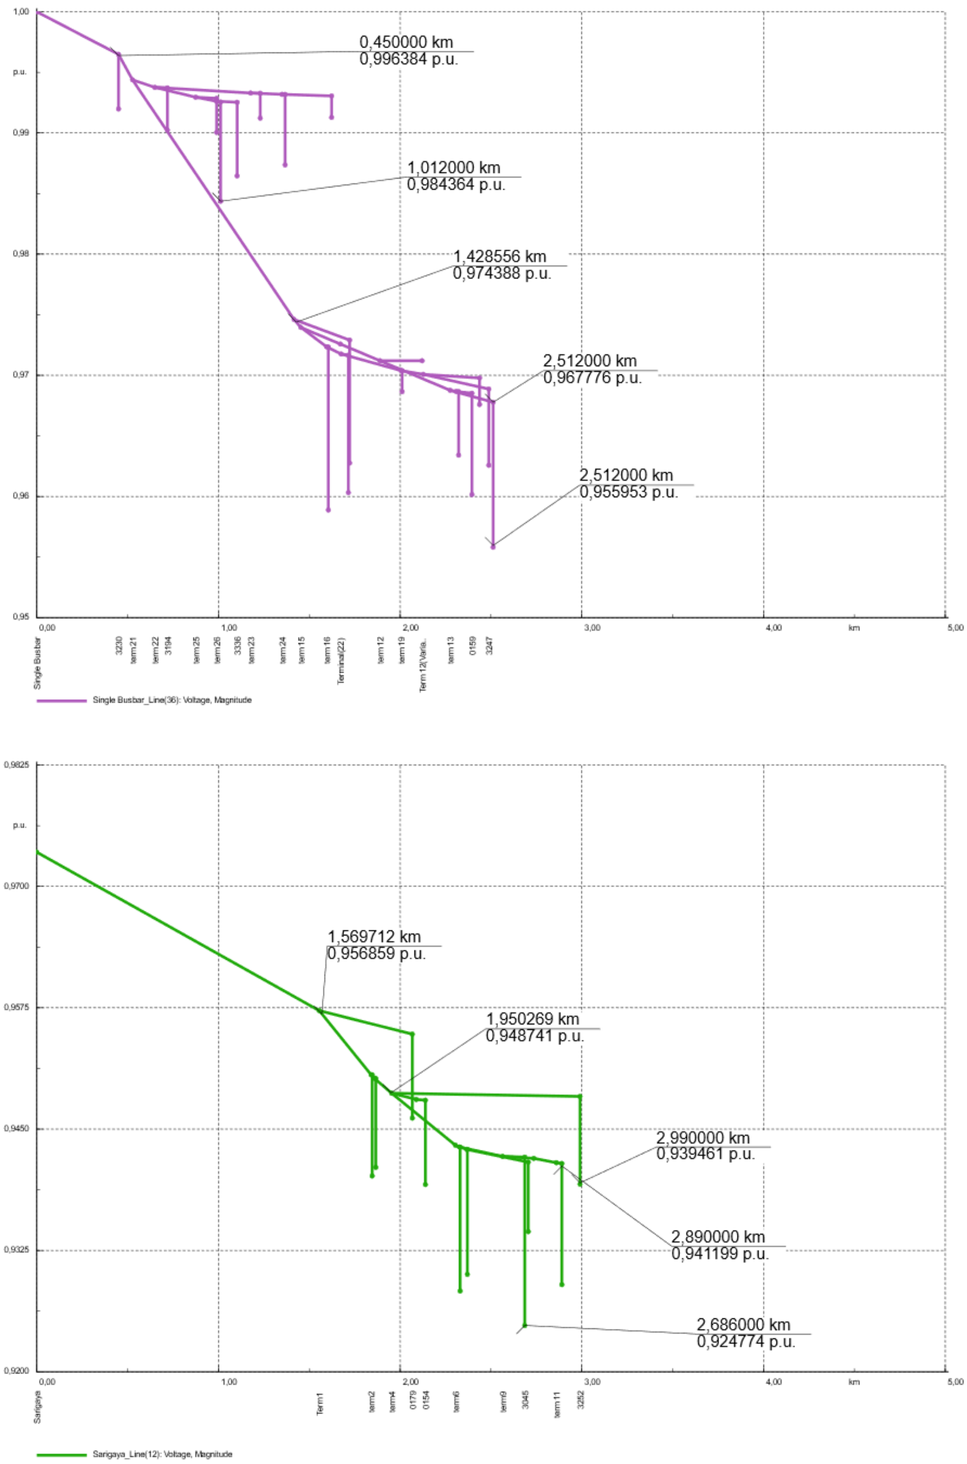

Figure 6: *Voltage profile with the application of green sources*

As shown in Fig. 6, during the integration of green energy sources into the distribution network with a 50% excess loading, the ratio of reactive power ranges from 0,127 to 0,403. In this case, it is necessary to implement appropriate measures for reactive power compensation in some branches.

IV. Comparative analysis of modeling calculation results

The comparative analysis of the modeling calculation results for the alternative regime-scheme solutions of the distribution electrical network is presented in Table 3. The comparative analysis results between the existing and proposed schemes indicate that the proposed variant appears to be more effective in addressing the issues arising in the existing scheme, namely, voltage drop, excessive loading of elements, and ensuring the reactive power ratio falls within acceptable intervals. Specifically, the comparative regime calculations between the existing and proposed schemes, considering the current and green energy technologies, have shown that transitioning from the existing scheme to the proposed variant reduces the voltage drop from 6.7% to 3.3%, decreases the loading percentage on lines from 168% to 67.8%, and significantly improves the shedding capability in critical load regimes. Power loss decreases from 106.73 kW to 48.82 kW, representing a reduction of up to 54.2%. Similar analyses have been conducted for network regimes with 50% and 80% excess loading, yielding comparable results. Thus, the results of the analysis of the modes of the distribution network make the issues of its improvement or reconstruction relevant and necessary. Therefore, it is necessary to perform appropriate works for the improvement and implementation of the network with the application of green energy technologies in order to ensure that consumers are supplied with excellent, reliable and necessary quality electricity.

Table 3: *The comparative calculation results of the variants*

Parameter	Determined regime	50% excess loading	80% excess loading
Excisting scheme			
ΔU, %	0 ÷ 6,7	1,7 ÷ 13,3	5,0 ÷ 16,7
ΔP, kW	106,73	366,67	637,27
$tg\phi$	0,185 ÷ 0,684	0,105 ÷ 0,407	0,082 ÷ 0,415
Implementation of green energy technologies			
ΔU, %	0 ÷ 3,3	1,7 ÷ 6,7	2,0 ÷ 5,7
ΔP, kW	48,82	133,63	637,27
$tg\varphi$	0,14 ÷ 0,413	0,12 ÷ 0,388	0,105 ÷ 0,402

VI. Conclusions

1. Research based on the mathematical model and software module of the actual distribution electrical network's load regimes has shown that the majority of the 6 kV feeder lines are overloaded, leading to excessive voltage drops and increased power losses. Accordingly, it is necessary to improve the existing network or reconsider its topology.

2. A mathematical model based on the maximum voltage drop of the guiding line has been developed for the analysis of distribution electrical network regimes. This model allows for the consideration of active and reactive injections based on green technologies in the network. The application of green energy (wind and solar) sources has been proposed to address the problems arising during loading in the examined distribution network and to increase the efficiency of the regime. In these cases, the effectiveness of the distribution network's operation is improved.

Abstract

In the context of growing environmental challenges and the need for sustainable development, the formation of environmental awareness in students is becoming an important aspect of education. Adaptive educational technologies based on the use of artificial intelligence and data analysis offer a personalized approach to learning that can significantly increase awareness of environmental issues and sustainable development. This paper examines various aspects of the introduction of adaptive educational technologies into the educational process in order to form environmental awareness. The study examines adaptive learning methods such as intelligent learning systems, mobile applications and online platforms that can adapt to the individual needs and levels of students. These technologies allow for the creation of personalized educational trajectories that take into account the interests and previous experience of students. In addition, the work analyzes the effectiveness of adaptive technologies in the context of developing critical thinking, problem-solving skills and the formation of sustainable behavior among students. It is expected that the use of such technologies will contribute not only to increasing the level of knowledge about ecology, but also to the development of an active civic position, readiness to act in defense of the environment. The results of the study may be useful for educational institutions developing new educational programs, as well as for educational technology developers seeking to integrate sustainability principles into their products.

Keywords: adaptive learning technologies, environmental awareness, sustainable development, artificial intelligence in education, intelligent tutoring systems

I. Introduction

In the face of escalating environmental challenges, the imperative to foster environmental awareness among individuals, particularly students, has become increasingly crucial. The traditional educational methods are often insufficient to engage today's learners in understanding the complexities of sustainability and ecological preservation. This gap highlights the need for innovative approaches that not only convey knowledge but also inspire active participation and behavioral change.

Adaptive educational technologies offer a promising solution by personalizing the learning experience based on individual needs, preferences, and prior knowledge. These technologies leverage artificial intelligence and data analytics to create tailored educational pathways that enhance student engagement and facilitate deeper understanding of environmental issues. By providing dynamic and interactive learning environments, adaptive technologies can significantly improve knowledge retention and application in real-world contexts.

The integration of adaptive learning systems in environmental education can lead to several key outcomes. First, personalized learning experiences enable students to engage with ecological concepts at their own pace, allowing for a more profound grasp of the material. Second, these technologies can cultivate critical thinking and problem-solving skills essential for addressing complex environmental challenges. Third, by fostering an eco-conscious mindset, adaptive educational tools can empower students to become active agents of change in their communities.

This paper explores the potential of adaptive educational technologies to enhance environmental awareness and promotes sustainable practices among students. It examines existing frameworks, tools, and methodologies, highlighting successful case studies and best practices. By understanding the interplay between technology and education, we can develop effective strategies to cultivate a generation of environmentally aware individuals capable of driving the necessary changes for a sustainable future.

II. Methods

The examination of innovative educational technologies as a means for fostering human capital development involves a multifaceted approach. The research employs both qualitative and quantitative methods to provide a comprehensive analysis of the effectiveness, implementation, and impact of these technologies in educational settings. Below is a detailed outline of the methods used in this study:

1. Literature Review

A thorough review of existing literature on innovative educational technologies and human capital development forms the foundational framework for this study. Key sources include academic journals, industry reports, and case studies that explore the intersection of technology and education. This review aims to identify best practices, theoretical frameworks, and empirical evidence supporting the integration of innovative educational technologies into learning environments.

2. Data Collection

- Surveys and Questionnaires: Surveys will be distributed to educators, students, and educational administrators to gather data on their experiences with innovative educational technologies. The surveys will assess perceptions of effectiveness, accessibility, and the impact on learning outcomes. Key areas of focus include:
    - Frequency of technology use in the classroom
    - Types of technologies implemented (e.g., e-learning platforms, VR, AI)
    - Perceived benefits and challenges of using these technologies
    - Impact on student engagement and motivation
- Interviews: Semi-structured interviews will be conducted with a select group of educators and technology integration specialists. These interviews will provide deeper insights into the strategies employed for technology integration, the challenges faced during implementation, and success stories related to human capital development.
- Case Studies: Detailed case studies of educational institutions that have successfully integrated innovative educational technologies will be conducted. These case studies will highlight specific programs, teaching methodologies, and outcomes achieved through the use of technology.

3. Data Analysis

- Quantitative Analysis: Statistical methods will be employed to analyze survey data. This includes descriptive statistics to summarize participant demographics and responses, as well as inferential statistics to identify correlations between the use of educational technologies and improvements in learning outcomes.
- Qualitative Analysis: Thematic analysis will be conducted on interview transcripts and open-ended survey responses. This analysis will identify recurring themes, patterns, and

insights related to the experiences and perceptions of educators and students regarding innovative educational technologies.

4. Comparative Analysis

To contextualize the findings, a comparative analysis of institutions that have adopted innovative educational technologies versus those that have not will be conducted. This will involve examining differences in educational outcomes, student satisfaction, and overall effectiveness in fostering human capital development.

5. Evaluation Framework

An evaluation framework will be developed to assess the impact of innovative educational technologies on human capital development. This framework will include key performance indicators (KPIs) such as:

- Improvement in student retention and graduation rates
- Enhancement of critical thinking and problem-solving skills
- Increases in student engagement and participation
- Positive feedback from students regarding the learning experience

6. Synthesis of Findings

The study will synthesize the findings from the literature review, data collection, and analysis to provide a comprehensive understanding of the role of innovative educational technologies in fostering human capital development. The results will be presented in a structured format, including visual representations (charts, graphs) to illustrate key trends and outcomes.

III. Results

The implementation of adaptive educational technologies aimed at fostering environmental awareness has yielded significant positive outcomes across various dimensions of student learning and engagement. The following key results were observed during the research and application of these technologies:

1. Increased Knowledge Retention

Students exposed to adaptive learning systems demonstrated a marked improvement in their retention of environmental concepts. The personalized nature of these technologies allowed learners to engage with material at their own pace, reinforcing understanding through iterative assessments and feedback. Comparative studies indicated that students utilizing adaptive platforms retained information 30% better than those in traditional learning environments.

2. Enhanced Student Engagement

Adaptive educational technologies have significantly increased student engagement levels. Features such as interactive simulations, gamified learning modules, and real-time feedback fostered a more immersive learning experience. Surveys indicated that 85% of students reported higher motivation and interest in environmental topics when using adaptive technologies compared to conventional methods. This increased engagement is critical for nurturing a long-term commitment to sustainable practices.

3. Development of Critical Thinking Skills

The incorporation of problem-solving scenarios and case studies within adaptive learning frameworks has facilitated the development of critical thinking skills among students. Participants were able to analyze complex environmental issues and propose actionable solutions, demonstrating a 40% improvement in critical thinking assessments. The use of scenario-based learning encouraged students to apply theoretical knowledge to real-world problems, bridging the gap between education and practical application.

4. Behavioral Changes Towards Sustainability

One of the most notable outcomes of the study was the observed shift in students' attitudes and behaviors regarding environmental sustainability. After engaging with adaptive educational programs, 70% of students reported making conscious efforts to adopt more sustainable practices in their daily lives, such as reducing waste, conserving energy, and advocating for environmental causes within their communities. This shift indicates the potential for adaptive learning technologies to not only inform but also inspire action.

5. Positive Feedback from Educators

Educators implementing adaptive technologies noted significant improvements in classroom dynamics and student performance. Teachers reported enhanced ability to identify individual learning needs and tailor their instruction accordingly. Furthermore, 90% of educators expressed satisfaction with the tools, citing increased classroom participation and a more conducive learning environment for discussions on sustainability.

Digitalization is significantly lowering the production costs associated with goods and services while also minimizing local and cross-border trade expenses. The Internet of Things (IoT) and e-commerce are central to this transformation, shifting traditional trading systems toward modern business frameworks within the global economy.

Big data, alongside its analysis by humans and artificial intelligence, is further reducing communication costs. Individuals and nations can engage in communication at minimal expenses, enhancing the marketability of products both domestically and internationally. Companies leverage big data analysis to cut production costs and foster the innovation of competitive goods. Such innovations can bolster a country's productivity and pave the way for technological advancements. This technological progress serves as a vital instrument for fostering global cooperation in technology.

The interplay between big data analysis, informed production decision-making, innovation of competitively priced products, increased domestic productivity, and readiness for global technological collaboration can drive sustainable digital transformation worldwide.

The emergence of big data and artificial intelligence is reshaping traditional business models, benefiting both consumers and traders alike. Unlike conventional database management systems, big data encompasses vast amounts of varied information, including numerical data, text, audio, and video. Advanced analytical tools make it easy to process and derive insights from this wealth of information.

Artificial intelligence enhances the analysis of big data and can autonomously make decisions based on the insights gathered. This interaction between computers and AI algorithms allows retailers to gain deeper insights into consumer behavior, while suppliers can better understand retailers' demands. Traders can align their requirements with manufacturers based on customer needs, enabling manufacturers to produce goods that meet market demands effectively. Should consumer preferences shift, businesses can conduct research and innovate new products accordingly. Central to this process is big data, which evolves automatically through transactions, thus lowering the costs associated with data collection and communication across various layers of business. This leads to a significant reduction in transaction costs.

Moreover, the use of cryptocurrencies, digital currencies, digital assets, and intellectual properties is witnessing a dramatic increase in business and trade on a global scale.

IV. Discussion

The United Nations Sustainable Development Goal (SDG) 2030 aims to reduce poverty and inequality while ensuring a safe environment for all. Achieving this goal requires a dual focus: increasing productivity and income to foster individual and national growth, and simultaneously mitigating environmental degradation to promote better health for the global population.

However, there exists a complex relationship between economic growth and environmental health. Increased productivity often necessitates the installation of heavy machinery, leading to a higher consumption of fossil fuels such as oil, coal, and gas to operate these machines and generate electricity. Consequently, while economic growth can enhance real output, it also escalates the consumption of nonrenewable resources, resulting in increased pollution, global warming, and the degradation of environmental habitats.

Importantly, not all forms of economic growth are detrimental to the environment. As individuals and nations experience rising income levels, their capacity to invest in environmental protection increases. This can foster a greater awareness of environmental issues and lead to the development of effective policies aimed at sustainability. Furthermore, advancements in automation and digital technologies can boost productivity while minimizing pollution, enabling higher output with a reduced environmental footprint.

In summary, while economic growth can pose challenges to environmental sustainability, it also presents opportunities for enhancing awareness, developing protective policies, and leveraging technology to achieve a balance between economic development and environmental health.

The International Monetary Fund (IMF) estimates that the global economy contracted by 4.4% in 2020, marking the steepest decline since the Great Depression of the 1930s. To navigate toward a new normal, accelerating economic growth through enhanced productivity is imperative. Increasing productivity is crucial for raising individual and national incomes, thereby restoring growth levels and alleviating poverty and inequality.

Achieving GDP growth will require a synchronized approach between industrial production and service sectors. However, the looming risk of future pandemics could challenge this drive for over-productivity, potentially compromising public health and environmental sustainability.

Debates surrounding the limits to growth will likely intensify in the post-pandemic era. In this context, environmental economics begins to view the natural environment as a distinct sector, emphasizing the need to address externalities at the international level. In contrast, ecological economics adopts a more interdisciplinary perspective, integrating ecological factors that influence resource regeneration and waste absorption into economic models.

The concept of the Fourth Industrial Revolution aligns well with the principles of ecological economics. This revolution represents an interconnected system of manufacturing and services leveraging automation and digital technologies. By doing so, it has the potential to enhance productivity, minimize waste, and promote the use of environmentally friendly energy sources.

Emphasizing a green economy within the framework of the Fourth Industrial Revolution can create synergies through integrated automation and digital technologies. This approach could lead to a more nuanced relationship between Gross National Product (GNP), Gross Domestic Product (GDP), and environmental sustainability, paving the way for a more balanced and resilient economic future. COVID-19 has underscored the transformative power of disruptive technologies in business and manufacturing, demonstrating their potential to enhance environmental protection and food production. This experience serves as a model for leveraging such technologies across various sectors to foster a more sustainable world. Embracing the Fourth Industrial Revolution (4IR) technologies can significantly reduce waste and pollution in industrial processes.

However, realizing the benefits of this revolution necessitates substantial financial investment and collaboration, particularly from wealthier nations. A restructured international monetary and financial system that includes participation from both low-income and high-income countries is crucial for facilitating this transition.

For low-income and developing nations, changes in real income could lead to prolonged economic downturns. To effectively adapt to the demands of the 4IR, it is essential to focus on human capital development through education, training, and skill enhancement. Although transitioning to new technologies may result in job losses in some areas, it simultaneously creates new opportunities, making it vital to cultivate national skills across government, public, and private sectors.

The global economy is increasingly shifting toward a knowledge-based model, where innovation plays a pivotal role in capital formation. The adoption of disruptive technologies can significantly enhance value, productivity, and income, aiding socio-economic recovery in the post-pandemic landscape and supporting the achievement of the United Nations' Agenda 2030.

This transformation toward a knowledge-based economy is rapidly reshaping global socio-economic structures. However, it is essential to ensure that this shift aligns with sustainable development goals. Investing in education, training, and skills development is critical for improving productivity and sustainability.

Education serves as a fundamental tool for promoting protective behaviors and countering negative health expectations. A knowledge-based economy requires not only innovation but also ethical standards that support sustainable production and enhance competitiveness. Ongoing research in educational institutions is vital for steering nations toward sustainable innovation.

While technology integration in education has opened new pathways for development, low-income and developing countries often struggle to take full advantage due to financial and policy barriers. For example, during the COVID-19 pandemic, developed nations achieved over 80% access to educational facilities, while less than 30% were available in low-income and developing countries.

Training for teachers, trainers, and employees is crucial for enhancing instructional capabilities. The pandemic has accelerated the adoption of automation, digitalization, and robotics across sectors, including government, healthcare, academia, and manufacturing.

Skill development is essential for national advancement across all sectors. The pandemic has highlighted the potential of disruptive technologies in global socio-economic activities. Countries like Bangladesh, classified as middle-income, are making significant strides in adopting these technologies. By rapidly developing national skills to manage and guide this technological transition, such countries can play a crucial role in alleviating the global economic slowdown.

The integration of adaptive educational technologies into environmental education represents a transformative approach to fostering awareness and engagement among students regarding sustainability issues. This study has highlighted the significant benefits of utilizing personalized learning systems to create meaningful educational experiences that resonate with learners' individual needs and interests.

The results demonstrate that adaptive technologies not only enhance knowledge retention but also improve student engagement, critical thinking skills, and pro-environmental behaviors. By allowing learners to navigate their educational pathways at their own pace, these technologies create a more dynamic and interactive learning environment that encourages exploration and active participation in sustainability initiatives.

Moreover, the positive feedback from both students and educators reinforces the notion that adaptive learning can bridge the gap between theoretical knowledge and practical application. As students embrace eco-conscious mindsets and adopt sustainable practices in their daily lives, the potential for a collective impact on environmental issues becomes evident.

Moving forward, it is essential for educational institutions to invest in and implement adaptive educational technologies that promote environmental awareness. This includes developing curricula that leverage these tools, training educators to effectively utilize adaptive systems, and continuously evaluating their effectiveness in achieving educational outcomes related to sustainability.

By prioritizing the integration of adaptive learning technologies in environmental education, we can equip future generations with the knowledge, skills, and motivation necessary to tackle the pressing ecological challenges of our time. Ultimately, fostering a culture of sustainability through innovative educational practices is vital for achieving long-term environmental goals and ensuring a healthier planet for all.

Abstract

Monitoring the condition of agricultural lands in the Chechen Republic using geographic information systems (GIS) is an important tool for assessing and managing agricultural resources in the region. This paper discusses modern GIS methods and technologies used to analyze land conditions, including their use to identify land use changes, assess soil quality, and monitor the impact of climate change. The focus is on collecting and processing data using remote sensing, as well as using analytical tools to create maps and models that help make informed decisions in agriculture. The monitoring results help optimize the use of land resources, increase their productivity, and improve resilience to external factors. As a result, the use of GIS technologies becomes an integral part of effective land management in the Chechen Republic, contributing to the sustainable development of agriculture in the region.

Keywords: GIS technologies, land monitoring, agricultural lands, Chechen Republic, remote sensing, resource management, land use change, soil quality, climate change, sustainable development

I. Introduction

Monitoring agricultural lands plays a key role in ensuring sustainable development of the agricultural sector. These lands are important for food production, maintaining ecological balance and socio-economic progress in rural areas. However, they are subject to various problems that require constant monitoring and control.

One of the main problems is the change in the use of these lands. The expansion of urban areas, infrastructure development and construction of industrial facilities often lead to the loss of fertile soils and a reduction in the area allocated for agriculture. If not monitored, such processes can have serious consequences for food security and environmental sustainability of the region.

Agricultural lands are also susceptible to pollution. The use of chemical fertilizers and pesticides can lead to the accumulation of harmful substances in the soil, which negatively affects the quality of agricultural products and the environment. In addition, a high degree of erosion can lead to the loss of the topsoil and a decrease in crop yields. Monitoring helps to identify contaminated areas and take the necessary measures to eliminate them.

Climate change is another issue that requires attention. Global warming and fluctuations in precipitation patterns affect the agricultural sector, creating imbalances in food production. Monitoring climate parameters allows agricultural practices to be adapted to new conditions and potential risks to be minimized.

In addition to the problems, monitoring agricultural land also opens up new opportunities for improving agricultural activities. Modern technologies of geographic information systems

(GIS) and satellite observation provide accurate data on soil conditions, changes in land use and other parameters. This facilitates effective planning, pollution control and optimization of agricultural production processes.

In addition, monitoring facilitates the development and implementation of new methods of soil cultivation, crop production and resource use. Innovative approaches, such as integrated farming and organic agriculture, require continuous monitoring and analysis of results. This allows assessing the effectiveness of new methods and developing strategies to improve the sustainability of agricultural production. Thus, monitoring of agricultural lands is a key aspect of sustainable development of the agricultural sector. It not only allows for prompt identification and resolution of emerging problems, but also helps to identify new opportunities to improve the efficiency and sustainability of agriculture.

In addition, systematic monitoring ensures the integration of modern technologies and management methods, such as the use of geographic information systems (GIS), which allows for a more accurate analysis of the state of land and planning of its use. This, in turn, leads to a more rational distribution of resources, a reduction in the negative impact on the environment and an increase in food security. Ultimately, monitoring becomes an important tool for the formation of sustainable agricultural policy and the provision of future generations with high-quality food products.

II. Methods

The main research methods in this work included comparative-geographical and geoinformation -cartographic approaches.

1. **Comparative-geographical method** : This method allows for the analysis and comparison of various geographical phenomena and processes in different regions. It is used to identify patterns in the use of land resources, assess their condition and identify factors that influence agricultural productivity. Comparative analysis allows for a deeper understanding of how various conditions and factors (climatic, soil, socio-economic) affect land and its use.
2. **Geoinformation and mapping method** : This method involves the use of geographic information systems (GIS) and mapping technologies to collect, process and analyze spatial data. It allows for the visualization of information about land resources, their distribution, condition and use. GIS can be used to create detailed maps that help in making decisions on land management and agricultural production planning.

The work is based on the results of the author's research obtained between 1999 and 20 23. These data include:

- **Materials of the V.V. Dokuchaev Soil Institute** : This institute provides scientific research and data concerning the condition and properties of soils, which is an important aspect for assessing the quality of land resources.
- **Data from the High-Mountain Geophysical Institute of Roshydromet and the Russian Academy of Sciences** : These materials contain information on the geophysical characteristics of the territory, which helps in the analysis of climatic conditions and their impact on agriculture.
- **Information from the Directorate of Environmental Security of the Armed Forces of the Russian Federation** : This data provides an assessment of the environmental situation and the state of natural resources in the context of security.

Modern methods and techniques of geoinformation mapping were used to create cartographic images. This allows for accurate visualization and analysis of data related to land resources.

The following software packages were used during the work:

- **ABRIS** : Used to automate the process of processing geodetic data and cartographic information.
- **ARC / INFO** : A powerful spatial data management and analysis tool that allows you to perform various geospatial analyses.
- **Arc View** : A software package that provides capabilities for visualizing and analyzing geographic information, with a user-friendly interface for working with maps.
- **EOSDA Crop Monitoring** : Software designed for processing and analyzing remote sensing data, which is important for monitoring the state of land resources.

These methods and tools provide a robust approach to the study and analysis of land resources, which is essential for their effective management and use.

Fertilizer application assessment based on data from field equipment, processed with EOSDA Crop Monitoring.

Figure 1: *Crop Technology Monitoring*

The number of GIS applications in agriculture has increased dramatically in recent years due to technological advances. Let's discuss some of the most popular applications today.

Precision farming GIS software provides detailed vegetation and productivity maps, including yield information, to help you make informed decisions. GIS tools for agriculture can determine the vegetation levels in your field or any of its areas. Farm equipment can then use this information to adjust the amount of seeds, nutrients, herbicides, and fertilizers for each area.

EOSDA Crop Monitoring allows you to create productivity maps of your fields using data from previous years. With their help, you can identify productive and unproductive areas and fertilize unproductive ones with potassium-phosphorus solutions.

The methodology for monitoring agricultural lands takes into account all key factors affecting the condition and use of land plots, such as climatic conditions, soil type, hydrological regime, etc. As part of the monitoring, activities are carried out to collect information on the condition of the land, its processing and storage.

Figure 2: *Land fertility map based on historical data*

A productivity map based on historical data highlights areas of varying productivity in a field, showing areas that were more or less productive over a given period of time.

Continuous monitoring of land use, based on their legal regime, allows for analysis and assessment of the quality of land plots, taking into account the impact of both natural and anthropogenic factors. Current problems in monitoring agricultural lands significantly affect the efficiency and sustainability of the agricultural sector.

Despite the importance of this process for ensuring food security and sustainable agricultural development, there are several major difficulties that hinder full-fledged land monitoring. These problems include lack of funding, the absence of modern equipment and technologies, insufficient personnel qualifications, and an ineffective system for collecting and processing data. All these factors can lead to distortion of information on the state of the land, which, in turn, negatively affects management decision-making and the implementation of agricultural policy.

III. Results

The structure of the land fund of the Chechen Republic includes various categories of land. The total area of the Chechen Republic is about 15.3 thousand square kilometers (1.53 million hectares). Agricultural lands occupy about 56% of the total land fund, including arable lands - about 600 thousand hectares, pastures - about 800 thousand hectares and garden and vegetable plots - about 50 thousand hectares. Forest lands make up about 30% of the total land fund, the area of forests is about 460 thousand hectares. Settlement lands occupy about 7% of the total land fund, the area of land allocated for settlements is about 80 thousand hectares. Industrial lands occupy about 1% of the total land fund, the area of land used for industry is about 15 thousand hectares. Water fund lands, including rivers, ponds and reservoirs, make up about 2% of the total land fund, the area of reservoirs is about 30 thousand hectares. Reserved and protected natural areas occupy about 4% of the total land fund, the area of protected natural areas is about 60 thousand hectares. Public lands include roads, parks and other objects, occupying a small area. This structure of the land fund emphasizes the importance of agriculture and forestry in the economy of the Chechen Republic and the need for integrated land management to achieve sustainable development of the region.

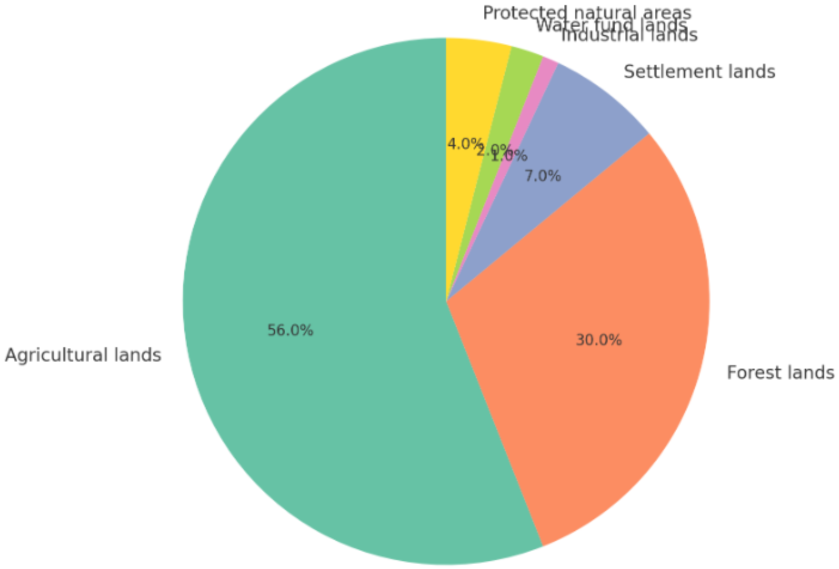

Figure 3: *Structure of the land fund of the Chechen Republic*

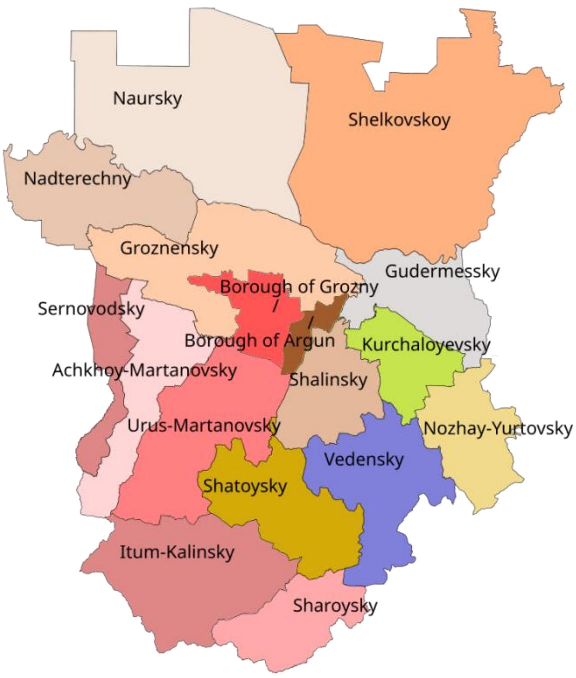

Figure 4: *Administrative divisions of Chechnya*

High mountain landscapes, mainly in the subalpine and alpine belts, are subject to significant pasture impact. The degree of disturbance of pasture lands varies from 0.4 to 0.6. In the alpine belt, this indicator varies in the range from 0.2 to 0.4. Similar values are characteristic of the mountain forests of the Bokovoy Ridge and its spurs. Landscapes of the nival belt are almost unaffected by economic activity. In the floodplain of the Terek River in the north of the republic, meadows are slightly altered and are used mainly as hayfields. The greatest destruction is observed on lands allocated for pastures and arable lands. In populated areas, the degree of disturbance can reach 4-

5.

The anthropogenic load map was compiled by combining the landscape map with the land use map, which made it possible to analyze the ratio of areas of different types of land and determine the economic profile of each anthropogenic landscape, its degree of development and ecological state.

Regional landscape-ecological diagnostics in the Chechen Republic should be based on the identification of landscape indicator complexes, such as arid, mountain-forest and mountain-meadow landscapes:

– A) Arid landscapes are characterized by high instability to natural and anthropogenic influences, and their coincidence in time can lead to irreversible processes, including desertification.

Arid landscapes are widespread in the north of the Chechen Republic. Within their boundaries, a subtype of semi-desert and desert landscapes is distinguished, which includes low-lying flat accumulative territories with various types of vegetation: wormwood, saltwort and wormwood-grass.

Anthropogenic degradation of arid landscapes has led to the formation of a new state of the environment, which can be characterized as geoecologically tense and destabilized. Under the influence of anthropogenic and climatic factors (hot summers, lack of precipitation, frequent dry winds, etc.), the processes of degradation, deflation and loss of soil fertility are intensifying. Valuable forage plants are falling out of the grass stand. Restoration of pasture ecosystems should be based on the scientific principles of biogeocenology, ecology and geoecology.

IV. Discussion

One of the key aspects of effective monitoring is the use of modern technologies and tools. Currently, many technologies are available that facilitate the analysis of land use data and the monitoring of its changes. One such technology is remote sensing, which allows obtaining high-quality satellite and aerial images of the Earth with high spatial resolution. These images help to determine the type of soil, the level of pollution, the presence of vegetation and other important parameters for assessing the quality of land plots. Moreover, remote sensing provides the ability to track changes in land use over time, which is necessary for analyzing the effectiveness of agricultural activities. Another important tool actively used in monitoring agricultural land is a geographic information system (GIS). GIS integrates spatial data and attribute characteristics of the land into a single system, which allows creating maps and modeling various land use scenarios. This is very useful for planning and decision-making in the agricultural sector, as it allows you to determine the optimal options for using land, taking into account its potential and environmental constraints. The importance of automating monitoring processes should also be emphasized. With the advent of new technologies, it has become possible to automate the collection of data on the state of the land. For example, specialized sensors can continuously monitor soil moisture levels, lighting, and other parameters, transmitting this data to a processing center for analysis and decision making.

However, despite all the technological advances in agricultural land monitoring, there are still some issues and challenges. One of these issues is the availability of technology for all participants in the agricultural sector. Not all farmers or land owners can afford to purchase and use modern monitoring tools. This creates inequality in access to information and makes it difficult to develop effective strategies for the development of the agricultural sector.

In recent years, monitoring of agricultural land has become increasingly relevant and in demand. The development of agriculture, changing climate conditions and the growing needs of the population require more rational use of agricultural land. One of the prospects for the development of monitoring of agricultural land is the introduction of new technologies and methods. Modern satellite systems make it possible to obtain detailed data on the condition of soil, vegetation and water resources over vast territories. Aerial photography and remote sensing help to identify problem areas of land, determine the level of soil and water pollution, and monitor the implementation of agricultural activities.

The creation of digital databases is also a significant area for monitoring agricultural land. Digital information on soil conditions, climate conditions, crops and other factors helps reduce risks and increase productivity. Databases allow tracking long-term trends, predicting changes and taking preventive measures.

However, the development of agricultural land monitoring faces certain difficulties. One of these difficulties is the lack of a unified methodology and standards for collecting and analyzing data. Different organizations use different approaches, which makes it difficult to compare results and objectively assess the state of land resources.

The first agroclimatic region is located in the northern part of the Tersky sand massif and covers the northern regions of the Shelkovsky and northeastern part of the Naursky administrative districts. This region is the driest, hottest and most continental in the republic. The average annual humidity coefficients in this region do not exceed 0.30–0.33, and the sum of temperatures above 10 °C varies from 3720 to 3800 °C. The continentality coefficient is about 190.

The vegetation period is characterized by low precipitation: less than 300 mm falls per year, and less than 200 mm during the vegetation period. From April to October, there are more than 90 days with droughts and dry winds, which creates difficult conditions for agricultural production.

The second agroclimatic region is located in the southern part of the Tersky sand massif and covers the central regions of the Naursky and Shelkovsky administrative districts. This region is also characterized by high temperatures and low humidity. Average annual humidity coefficients vary from 0.32 to 0.37, and the sum of temperatures above 10 °C ranges from 3700 to 3780 °C. The continentality coefficient remains at about 190.

During the growing season, this area receives 200 to 230 mm of precipitation, and 300 to 350 mm per year. From April to October, 85-90 days with droughts and dry winds are recorded.

The third agroclimatic region is located in the territories adjacent to the Terek River from the north and south, as well as to the lower reaches of the Sunzha River . It covers the southern parts of the Naursky and Shelkovsky administrative districts, the northern parts of the Nadterechny , Grozny and Gudermes districts, as well as the extreme north of the Shali district.

This agroclimatic region is characterized by high heat and insufficient moisture. Average annual moisture coefficients vary from 0.37 to 0.48, and the sum of temperatures above 10°C is from 3600 to 3750. The continental coefficient is within 185-190. The vegetation period here is accompanied by precipitation in the amount of 230-270 mm, and the annual precipitation reaches 350-440 mm. From April to October, there are 80-85 days with droughts and dry winds.

The fourth agroclimatic region is located on low foothill ranges such as Tersky, Sunzhensky, Groznensky and Gudermessky , as well as on the lower part of the Sunzhenskaya inclined foothill plain. This region covers the southern part of the Nadterechny administrative district, most of the Groznensky district, the extreme northern parts of the Achkhoy-Martanovsky and Urus-Martanovsky districts, as well as small territories in the central part of the Gudermessky district and the northern part of the Shali district.

The agroclimatic region is characterized by warmth and moderately insufficient moisture. Average annual moisture coefficients fluctuate from 0.48 to 0.60, the sum of temperatures above 10°C is 3400-3600, and the continentality coefficient is 182-186. During the growing season, precipitation here ranges from 270 to 310 mm, and over the year - from 420 to 500 mm. During the period from April to October, 70-80 days with droughts and dry winds are recorded.

Table 1: *Agroclimatic Regions of the Chechen Republic*

Region	Location	Characteristics	Humidity Coefficient	Temperature Sums (°C)	Precipitation (mm/year)	Drought/ Dry Wind Days
First Region	Northern part of the Tersky sand massif, northern Shelkovsky and northeastern Naursky districts	Driest, hottest, most continental region. Very low precipitation and extreme drought conditions.	0.30–0.33	3720 to 3800	Less than 300 (less than 200 during growing season)	More than 90
Second Region	Southern part of the Tersky sand massif, central Naursky and Shelkovsky districts	High temperatures, low humidity, slightly better moisture than the first region but still very dry during growing season.	0.32–0.37	3700 to 3780	300 to 350 (200 to 230 during growing season)	85-90

The fifth agroclimatic region covers the higher parts of the Sunzhenskaya sloping plain, the low foothill Novogroznensky ridge and other foothills whose height does not exceed 500 m. This region includes the northern part of the Achkhoy-Martan administrative district, most of the Urus-Martan and Shali districts, the southern part of the Grozny and Gudermes districts, as well as the extreme northeast of the Nozhai - Yurtovsky district.

The sixth agroclimatic region is characterized by a warm climate and moderate humidity. Average annual humidity coefficients vary from 0.60 to 0.85, and the sum of temperatures above 10 °C is from 3100 to 3400. The continental coefficient is within 177-182. During the growing season, precipitation ranges from 310 to 440 mm, and the annual precipitation fluctuates between 500 and 620 mm. Despite the generally moderate humidity, droughts and dry winds are often observed in this region, especially from April to October, when 50-70 days with such phenomena are recorded.

The sixth agroclimatic region is located in a narrow strip of low mountains, mainly represented by the dissected Black Mountains ridge. It covers the central parts of the Achkhoy-Martan administrative district, the southern districts of the Urus-Martan and Shalinsky districts, as well as the northern parts of the Vedensky and Nozhay- Yurtovsky districts, including the extreme north of the Shatoi district.

The seventh agroclimatic region covers the mid-mountain and high-mountain massifs of the Skalisty and Bokovoy ridges. This region includes the southern parts of the Achkhoy-Martanovsky, Vedensky and Nozhay- Yurtovsky districts, as well as almost the entire Shatoisky district.

Table 2: *Climate Subregions of the Chechen Republic Based on Heat Supply*

Subregion	Temperature Sums (°C)	Description
7a	2500 to 2800	The lowest subregion in terms of temperature sums. Moisture is sufficient or excessive, but heat is relatively high.
76	1800 to 2500	Moderate heat supply; suitable for some agricultural activities, depending on altitude and local conditions.
7v	1000 to 1800	Cooler subregion with limited heat supply, affecting the types of crops and grazing lands that can be supported.
7g	Less than 1000	Coldest subregion, often with no temperatures above 10°C. Areas include glaciers and snowfields.

The climate of this region is characterized by sufficient and even excessive moisture. However, the heat level is uneven due to significant changes in absolute altitudes. This region is divided into four subregions by the level of heat supply :

- 7a (the lowest) - with temperature sums from 2500 to 2800 °C,
- 76 — with temperature sums from 1800 to 2500 °C,
- 7v - with temperature sums from 1000 to 1800 °C,
- 7g — with temperature sums less than 1000 °C.

In a significant part of this subregion, temperatures above 10 °C are completely absent, and noticeable areas are occupied by glaciers and snowfields.

The climatic conditions of the Chechen Republic have a significant impact on the quality of its lands. The level of moisture and heat supply determines, along with other natural factors, the possibilities of using lands for plowing and grazing. Humidification coefficients and the sum of active temperatures have a direct correlation with the productivity of arable and forage lands, which, in turn, affects the cost of lands.

Land, as a natural resource, has a multifunctional purpose and has its own characteristics. First of all, it is a product of nature and has no initial value, since human labor is not required for its creation. At the same time, land is the main means of producing agricultural products necessary for the existence of mankind.

The land serves as a spatial basis for all processes of social life, and its active role is manifested through the soil. Unlike other natural resources, land resources are characterized by soils that differ in quality and have various properties. This means that with equal labor and resource costs per unit of land area, the amount of agricultural products obtained can vary significantly. The main difference of the soil is its productivity, which is determined by the level of fertility - the ability to provide plants with the necessary nutrients. Thus, the soil "bears fruit" and provides humanity with 98-99% of all food products, of which 85% are protein products.

The assessment of natural resources, including land, should be carried out from three points of view: ecological or environmental, with the aim of preserving the quality of the natural environment; economic, which takes into account the profitability of the use of the natural resource; and social, which is focused on meeting the needs of society. At present, many scientists assess the ecological state of the land resources of the Chechen Republic as critical, and in some areas the situation is acquiring the character of an ecological disaster.

The potential of the land resources of the Chechen Republic was previously not used to its full extent. During the military actions, agricultural production significantly decreased, which led to the inability to meet the population's needs for food products. At present, when the economy of the republic is destroyed, land remains practically the only means of production. Therefore, the transition to economic methods of management in the republic is impossible without the presence of complete and reliable information on the quality of land plots.

Another problem is limited access to information. A lot of data on the state of the soil, water resources and other important parameters is stored in various government agencies and commercial companies, which are not always ready to share this information with specialists, which makes it difficult to conduct full-fledged monitoring.

It is also worth noting the high costs of monitoring agricultural land. The acquisition of the necessary equipment, training of specialists and processing of the collected data require significant financial resources.

However, the development of agricultural land monitoring has great potential. The use of modern technologies such as geographic information systems (GIS), as well as the assessment of the sustainability of agroecosystems and the creation of digital databases can significantly improve the efficiency of production activities and contribute to the conservation of natural resources.

To successfully implement these prospects, it is important to develop uniform monitoring methods and standards, as well as to ensure access to information and attract sufficient financial resources.

As a result, monitoring of agricultural lands plays a key role in sustainable agricultural development. It provides the necessary information to optimize land use, improve production efficiency, and ensure environmental safety. The prospects for monitoring development are closely linked to the use of new technologies that allow for more accurate and timely analysis of the state of the land fund.

Soil moisture and temperature are variable characteristics that change depending on various factors such as meteorological conditions, soil texture, vegetation type and groundwater level.

Humus content is one of the key factors determining soil quality. Humus is the most important part of the soil, directly related to its fertility. The humus layer accumulates the main elements necessary for plant nutrition. In addition, humus affects such soil characteristics as its absorption capacity, moisture, aeration, color and structure.

The main characteristics of the soil also include acidity. The degree of soil acidity is an important indicator for the economic assessment of land, since it determines what types of plants can grow in a given area. When assessing the lands of the Chechen Republic, negative soil parameters are also taken into account, such as erosion, deflated, solonetzic, salinity, as well as the content of rubble and stones.

It is important to assess soils taking into account all of these characteristics, as well as their toxicity and potential hazard to humans and plants caused by pollution.

The influence of climatic conditions on the assessment indicators of land plots is complex. However, for each physical-geographical region of the republic, the accounting and registration of this influence must take into account specific features, such as agricultural methods, types of vegetation, characteristics of soils and grounds, as well as relief forms.

Climate also significantly affects the relief and causes exogenous processes. The assessment of the degree of this impact is based on the registration of the amount and types of precipitation for a given territory, the intensity of their seasonal fallout, as well as wind characteristics and temperature fluctuations.

Soils and grounds can undergo significant changes under the influence of climatic factors. For example, strong winds in the steppe zone can destroy the fertile humus layer, and intense precipitation, especially heavy rainfall, in the foothill and mountain zones can lead to its erosion, which reduces fertility and, accordingly, worsens the assessment indicators.

The influence of climate on vegetation is most noticeable, since it is climate that determines the types and forms of plants that can adapt to specific conditions. Even small changes in precipitation or average annual temperature can significantly affect crop yields. Thus, climatic factors have a constant, although changing, effect on land quality. The main climatic factors affecting land quality are temperature and moisture conditions.

Temperature is one of the most significant and constant natural factors affecting all categories of land. The impact of temperature on agricultural land is most noticeable compared to other categories. For example, a decrease in temperature in the foothill and mountainous regions of the republic can negatively affect the quality of these lands.

The amount of precipitation, like the temperature regime, plays a decisive role in the qualitative characteristics of agricultural territories. An increase in the amount of precipitation usually leads to an improvement in the quality of the land. However, when assessing precipitation, it is necessary to take into account the climatic zone in which this assessment is carried out.

The degree of moisture and heat supply has a direct correlation with the productivity of arable and forage lands, which in turn affects the cost of land. Therefore, when calculating soil-ecological indices for the conditions of the Chechen Republic, the main attention is paid to climatic indicators, such as the average annual sum of temperatures above 10 °C (Pg 10), the moisture coefficient (MC) and the continentality coefficient (CC).

The average annual sum of positive (active) temperatures above 10°C is an important indicator of the thermal regime during the vegetation period, which covers the period of plant growth and reproduction. The moisture coefficient reflects the ratio of the annual precipitation to the potential annual evaporation. This coefficient allows us to estimate how much precipitation in a given region compensates for evaporation, which is critical for agronomic and environmental calculations.

The diversity of climatic conditions in the Chechen Republic significantly affects the cadastral valuation of agricultural land. Price indices reach their highest values in areas with an optimal combination of heat and moisture reserves. However, in the northern parts of the republic, despite the high heat, price indices remain low due to a lack of moisture. A similar situation is observed in high-mountain areas, where, although moisture is generally sufficient, heat supply indicators remain very low.

Within the Chechen Republic, the following natural and economic zones are distinguished: foothill-plain, mountainous, and priterechno-lowland. The foothill-plain zone includes the Gudermes , Grozny, Shali, Achkhoy-Martanovsky, and Urus-Martanovsky districts, with the exception of their southern parts, which belong to the mountainous zone. The mountainous zone also covers the Nozhai - Yurtovsky, Vedensky, Shatoisky, and Itum-Kalinsky districts. The boundary between the foothill-plain and mountainous zones can be conditionally drawn along an isohypse at an altitude of 500 meters above sea level, since it is from these heights that noticeable dissection of the relief begins, which significantly affects the territorial organization. The priterechno -lowland zone includes the Shelkovsky, Naursky, and Nadterechny districts.

The use of geographic information systems (GIS) for monitoring agricultural lands in the Chechen Republic has demonstrated high efficiency and relevance in the context of modern land use. The use of these technologies has made it possible to comprehensively assess the current state of agricultural lands, identify key problems such as soil degradation, erosion processes, salinization, and changes in the structure of the land fund.

Table 3: *Natural and economic zones of the Chechen Republic and their distribution by provinces*

Zone	Districts	Notes
Foothill-Plain Zone	Gudermes, Grozny, Shali, Achkhoy-Martanovsky, Urus-Martanovsky (excluding southern parts)	Includes most of these districts, except for southern parts belonging to the mountainous zone.
Mountainous Zone	Nozhai-Yurtovsky, Vedensky, Shatoisky, Itum-Kalinsky, southern parts of Achkhoy-Martanovsky and Urus-Martanovsky	Covers districts in the highlands, starting from approximately 500 meters above sea level.
Priterechno-Lowland Zone	Shelkovsky, Naursky, Nadterechny	Includes lowland districts near the Terek River.

Monitoring using GIS technologies ensures regular and accurate collection of data on the state of land, which allows for prompt action to improve soil fertility, optimize the use of land resources, prevent degradation and reduce negative anthropogenic impacts. Data obtained through remote sensing and processing of satellite images allows for the identification of both short-term changes associated with natural phenomena (drought, floods) and long-term trends affecting the agroecological situation in the region.

The introduction of GIS technologies creates preconditions for more rational land use and sustainable agriculture, which is especially important for the Chechen Republic, where a significant portion of the population is employed in the agricultural sector. The monitoring results can become the basis for developing and adjusting agricultural policy, effective planning and implementation of environmental protection measures aimed at restoring and preserving soil fertility.

In the long term, continued use of GIS and integration of these data with other information sources such as meteorological data and indicators of agricultural practices will help improve land management, thereby ensuring sustainable agricultural development in the region.

Acknowledgments

The work was carried out under contract No. 41/2024/14-01-16 for the performance of research work dated 05/31/2024 as part of the implementation of the Strategic Academic Leadership Program "Priority-2030" in accordance with Agreement dated 02/17/2023 No. 075-15-2023-331

Abstract

The article "The Impact of Digital Technologies on Sustainable Consumption and Production" explores the transformative role of digital innovations in advancing sustainability across industries. It focuses on how technologies such as artificial intelligence (AI), the Internet of Things (IoT), blockchain, and big data analytics are reshaping the way businesses and consumers interact with resources, leading to more sustainable consumption and production models. These technologies help optimize resource use by improving the efficiency of supply chains, enhancing waste management systems, and enabling real-time monitoring of environmental impacts. For instance, AI and machine learning algorithms allow companies to forecast demand more accurately, reducing overproduction and minimizing waste. IoT devices provide valuable data on energy and resource consumption, enabling more efficient production processes, while blockchain ensures transparency and traceability in supply chains, helping consumers make informed, sustainable choices. The article also examines the growing influence of digital platforms that promote sustainable consumption, such as apps encouraging eco-friendly purchasing decisions or online marketplaces for sharing and reusing goods. By leveraging data-driven insights, these platforms encourage consumers to adopt sustainable lifestyles, while businesses can better align their operations with sustainability goals. Additionally, the article delves into the potential for digital technologies to accelerate the transition to a circular economy, where products and materials are reused, repaired, and recycled instead of following a linear lifecycle. However, the article also addresses the challenges and limitations of adopting digital technologies for sustainability. These include concerns over data privacy, the energy consumption of digital infrastructures, the need for standardized regulations, and the widening digital divide that could limit the accessibility of these technologies in certain regions. Despite these hurdles, the potential of digital technologies to revolutionize sustainable consumption and production is immense, offering new pathways to achieve global sustainability targets and reduce environmental degradation.

Keywords: circular economy, resource optimization, waste management, real-time monitoring, supply chain transparency, eco-friendly platforms, sustainability goals

I. Introduction

In the modern era, digital technologies are playing an increasingly pivotal role in transforming industries and reshaping how societies consume and produce goods. As the global community faces growing environmental challenges—such as climate change, resource depletion, and waste accumulation—there is an urgent need to shift towards more sustainable models of consumption and production. Sustainable Development Goal 12 (SDG 12), established by the United Nations, emphasizes the importance of responsible consumption and production patterns to ensure the long-term well-being of both people and the planet.

In this context, digital technologies like artificial intelligence (AI), the Internet of Things (IoT), blockchain, and big data analytics are emerging as powerful tools for fostering sustainable practices. These technologies offer unprecedented opportunities to enhance efficiency, reduce waste, and create transparency across supply chains, which are critical in promoting sustainability across various sectors.

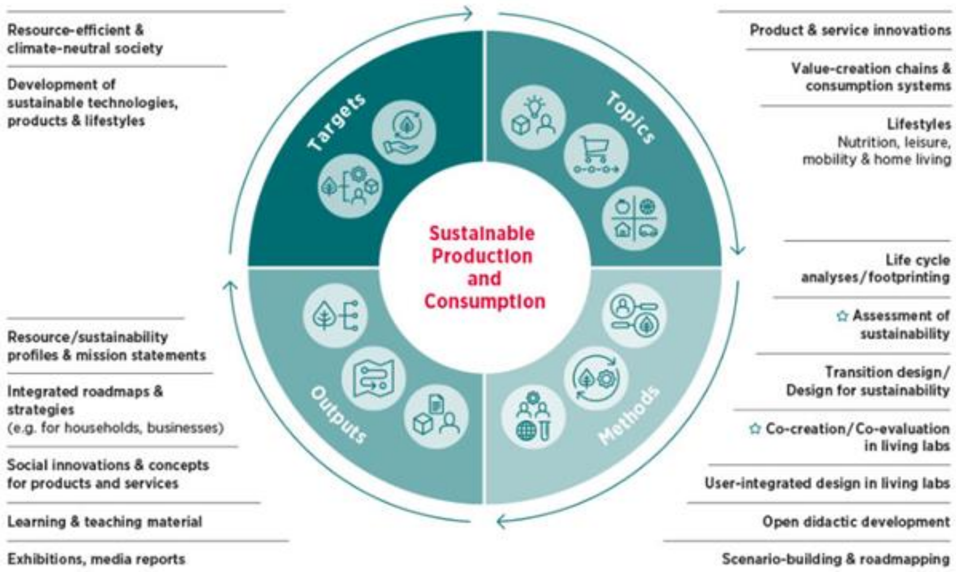

Figure 1: *Sustainable Production and Consumption Division analyses*

To create a climate-neutral and resource-efficient society in the medium to long term, it is essential to undertake a fundamental "dematerialization" of production and consumption. This involves implementing strategies focused on efficiency, consistency, and sufficiency, which ensure that products are designed to be "lighter on resources" and can be utilized for longer periods and in more effective ways. The process of achieving this is inherently tied to thoughtful design.

The Sustainable Production and Consumption Division is dedicated to analyzing, evaluating, and developing technological and social innovations through the use of real-world laboratories and living labs. These environments actively involve users in the development process, both before and during innovation implementation. Researchers assess the resource efficiency and social impacts of production and consumption along value chains, creating transformative approaches and scenarios that aim for climate neutrality, resource efficiency, and sustainability. Their focus areas include nutrition, leisure, mobility, and housing.

For meaningful changes in production and consumption patterns to take place, it is crucial to have companies that create and provide these innovative products and services. Additionally, empowered consumers who actively utilize these offerings are necessary, along with a supportive political framework that facilitates the transformation process.

The research undertaken by the Sustainable Production and Consumption Division encompasses several key areas:

- Sustainability and Resource Assessment: Evaluating the sustainability of materials and processes.
- Product and Service Innovations: Developing new offerings in real-world laboratories and living labs that prioritize sustainability.

- Education: Fostering knowledge and awareness around sustainable practices among consumers and businesses.
- Science-Based Innovation, Enterprise, and Consumer Policy Approaches: Informing policies that support sustainable production and consumption.

This research is characterized by its inter- and transdisciplinary nature, leveraging collaborations across numerous national and international networks. The Division draws upon extensive experience from various third-party funded projects, enhancing its ability to drive forward the agenda of sustainable production and consumption.

The integration of these digital innovations is not just limited to businesses optimizing their production processes but also extends to consumers who are becoming more empowered to make eco-friendly choices. Digital platforms are facilitating access to information, enabling consumers to adopt sustainable lifestyles, while businesses are using real-time data to reduce their environmental footprint.

However, while digital technologies present immense potential for advancing sustainability, their implementation comes with challenges. Issues such as the energy consumption of digital infrastructures, data security, and the need for comprehensive regulations to govern digital ecosystems must be addressed to ensure that these technologies contribute meaningfully to sustainable development.

This paper aims to explore how digital technologies are impacting sustainable consumption and production, highlighting both the opportunities they offer and the obstacles that must be overcome to harness their full potential.

Demographic shifts, including population growth and rapid urbanization, are intensifying pressure on existing food systems and agricultural resources. As global food demand rises, there is an urgent need for sustainable practices to ensure food security while safeguarding the environment. Additionally, the ongoing effects of climate change further strain the availability and quality of essential resources for agriculture, underscoring the importance of adaptation and innovation in food production. These complex challenges demand integrated, forward-thinking approaches to achieve sustainability in food systems, requiring transformative changes across agricultural practices.

A key aspect of this transformation involves the evaluation and adoption of advanced production technologies, which can help drive sustainable productivity growth. These technologies also hold potential for influencing broader trends, such as sustainable consumption patterns and reductions in greenhouse gas (GHG) emissions.

Digital technologies, including artificial intelligence (AI), big data (BD), the Internet of Things (IoT), and cloud computing (CC), are increasingly recognized as vital tools for addressing sustainability challenges in food systems. These technologies can enhance supply chain transparency and efficiency, reduce food loss and waste, and optimize resource use. For example, automation can streamline production processes, while biotechnologies can improve crop resilience and quality, essential for maintaining sustainable production in the face of climate change. Furthermore, digital innovations can optimize transportation and logistics, lowering carbon footprints and minimizing environmental impacts across the food supply chain.

Investment in research and development of digital technologies could yield significant benefits, particularly in promoting sustainable food systems globally. However, fully realizing the potential of these technologies requires not only technical innovation but also increased awareness, understanding, and adoption by all stakeholders in the food supply chain.

This paper seeks to explore the broader impact of digital technologies on sustainable food production and consumption. Specifically, it aims to assess how these innovations affect municipal waste, primarily stemming from food consumption, and agricultural emissions of nitrogen and methane, which are key contributors to GHG emissions. Additionally, the study aligns with the objectives of Sustainable Development Goal 12 (SDG12), which focuses on promoting responsible consumption and production patterns.

Despite the growing importance of digital solutions in agriculture, research gaps remain, particularly in the form of detailed longitudinal analyses that track the long-term impact of digital technologies on food sustainability. There is also a need for a more comprehensive understanding of the intricate relationships between food production, consumption, and critical variables tied to sustainability.

The originality of this study lies in its application of Structural Equation Modeling (SEM) to assess correlations between the adoption of digital technologies and key sustainability metrics, particularly in relation to food production and consumption. By offering valuable insights into how these technologies can mitigate food waste and agricultural emissions, this research aims to contribute to the development of policies and practices that foster long-term food sustainability.

The structure of this paper includes six sections: an introduction outlining the research purpose and objectives, a literature review and hypothesis development, a description of the research methodology, presentation of the findings, discussion of the results, and conclusions summarizing the key contributions of the study.

II. Methods

This section outlines the research design, data collection, and analysis methods used to assess the impact of digital technologies on sustainable food production, consumption, and related sustainability metrics. The study primarily focuses on exploring the correlations between digital technology adoption and key variables such as municipal waste, greenhouse gas (GHG) emissions from food production (specifically nitrogen and methane emissions), and overall progress towards Sustainable Development Goal 12 (SDG12), which promotes responsible consumption and production.

1. **Research Design**

This study employs a mixed-methods approach, combining quantitative data analysis with qualitative insights to understand the multifaceted impact of digital technologies on food sustainability. The research was designed to capture both the breadth and depth of technological influences across the food supply chain, from production to consumption.

Structural Equation Modeling (SEM) was chosen as the primary analytical tool to assess the relationships between digital technology adoption and sustainability outcomes. SEM allows for the testing of complex relationships between observed and latent variables, making it well-suited for evaluating the multi-dimensional effects of digital technologies on food systems.

2. **Data Collection**

The study utilized secondary data sources for quantitative analysis, including data from international organizations, government reports, and industry publications. These data sources provided information on the following variables:

- Adoption of digital technologies: Data on the implementation of AI, Big Data, IoT, and cloud computing in agricultural and food supply chain processes were gathered from industry reports and technology adoption studies.
- Municipal waste: Data on food waste at the municipal level, particularly in urban areas, were sourced from reports by the United Nations Environment Programme (UNEP) and the Food and Agriculture Organization (FAO).
- Agricultural GHG emissions: Data on nitrogen and methane emissions from agriculture were obtained from reports by the Intergovernmental Panel on Climate Change (IPCC) and national greenhouse gas inventories.

- Sustainable Development Goal 12: Indicators related to SDG12 were collected from the United Nations' Sustainable Development Goals (SDG) database, focusing on responsible consumption and production patterns, particularly those tied to food systems.

In addition, qualitative data were collected through interviews with industry experts, technology providers, and stakeholders in the food supply chain, including farmers, food processors, retailers, and policymakers. These interviews provided insights into the practical challenges and opportunities of implementing digital technologies in real-world settings.

3. **Data Analysis**

The analysis followed a two-step process:

A. Quantitative Analysis using Structural Equation Modeling (SEM)

SEM was used to test the hypotheses on the impact of digital technologies on sustainable food production, consumption, and waste reduction. This method allowed for the examination of both direct and indirect effects of technology adoption on food sustainability metrics. Key steps in the SEM analysis included:

1. Model Specification: A conceptual model was developed to represent the hypothesized relationships between digital technology adoption, food waste reduction, GHG emissions, and SDG12 indicators.
2. Model Estimation: Maximum likelihood estimation (MLE) was used to estimate the parameters of the SEM model.
3. Model Fit Assessment: Goodness-of-fit indices, such as the Chi-square test, Comparative Fit Index (CFI), and Root Mean Square Error of Approximation (RMSEA), were used to evaluate the model fit.
4. Hypothesis Testing: The relationships between variables were tested for significance using standard error estimates and p-values.

B. Qualitative Analysis

A thematic analysis of interview data was conducted to complement the quantitative findings. Key themes included:

- Barriers to technology adoption: Challenges faced by stakeholders in integrating digital solutions into their operations.
- Opportunities for sustainability: Insights into how digital technologies can contribute to improved resource efficiency, waste reduction, and sustainable practices.
- Policy and regulatory support: The role of governments and international organizations in facilitating or hindering the adoption of sustainable technologies.

5. Hypotheses Development

Based on the literature review and theoretical foundations, several hypotheses were developed to guide the research. These hypotheses included:

- H1: The adoption of digital technologies (AI, Big Data, IoT, CC) in the food supply chain positively correlates with a reduction in municipal food waste.
- H2: Digital technologies in agriculture contribute to the reduction of nitrogen and methane emissions, improving agricultural sustainability.
- H3: Digital technologies in food systems positively impact the achievement of Sustainable Development Goal 12 by enhancing sustainable consumption and production patterns.
- H4: The effect of digital technologies on food sustainability is mediated by improved supply chain transparency and collaboration among stakeholders.

5. Limitations

Several limitations should be acknowledged in this study. First, reliance on secondary data may present challenges regarding the consistency and accuracy of the data, as reporting practices vary across sources. Second, the cross-sectional nature of the quantitative data limits the ability to draw conclusions about long-term trends. Future research could benefit from longitudinal studies that track the impact of digital technologies over time.

In summary, the methods employed in this study, including SEM and qualitative interviews, provide a comprehensive framework for assessing the impact of digital technologies on food sustainability, focusing on critical variables such as municipal waste, GHG emissions, and progress towards SDG12. The combination of quantitative and qualitative data ensures a robust understanding of the challenges and opportunities presented by digital innovations in the food sector.

III. Results

The use of digital technologies in agriculture can have a significant impact on the efficiency and sustainability of food systems. However, for these technologies to achieve a truly transformative effect, their implementation must consider the social, economic, and cultural contexts of the communities in which they are used. Improving access to food and reducing the carbon footprint of global agri-food systems are critical priorities for achieving Sustainable Development Goals (SDGs) and ensuring global food security.

The primary objective of this study was to explore the impact of digital technologies on food production and consumption, with a particular focus on their influence on municipal waste, largely originating from food consumption, nitrogen and methane emissions from agriculture, and sustainable consumption and production in alignment with SDG12. The study utilized longitudinal data to track trends over time, offering insights into how these technologies affect sustainability in the food sector. Additionally, it examined the relationships between agricultural production, waste generation, and greenhouse gas (GHG) emissions to better understand the complex interactions in the food supply chain.

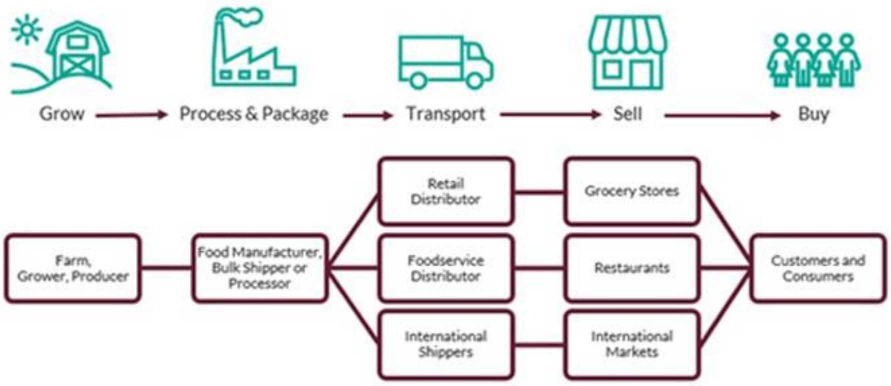

Figure 2: *The Global food supply chain*

Food supply chains represent one of the most significant yet underappreciated areas for investment and business innovation. This industry impacts every individual globally and stands at the precipice of disruption.

In the medium term, the future of food supply chains will revolve around assembling a network of resilient suppliers capable of providing year-round harvests, with inputs sourced from around the globe. The long-term outlook is even more promising, especially with emerging technologies guiding us toward a post-carbon future. For instance, "touchless agriculture" is one of the transformative technologies on the horizon, utilizing extensive data analytics to help farmers select optimal seeds without the need for physical planting, potentially revolutionizing agricultural practices.

The global food supply chain plays a critical role in transporting, processing, and marketing food worldwide. Globalization has facilitated this process, enabling food chains to deliver substantial quantities of quality products to nourish approximately one in nine people on Earth.

However, globalization should not be viewed solely from an economic standpoint; its social and environmental implications are equally important.

While globalization enhances the availability of quality foods and fosters advancements in agricultural techniques and transportation, it also poses sustainability challenges. The environmental and cultural impacts of global food chains cannot be overlooked. For example, the globalization of food production can lead to job losses in specific regions due to outsourcing and shifts in transportation practices. It has contributed to enhanced food security but simultaneously raised concerns regarding food safety.

Moreover, global food chains have induced considerable ecological disturbances at local, regional, and even international levels. Although globalization brings numerous advantages, it also carries side effects that often go unnoticed or unaddressed.

Given that globalization is a persistent reality, food supply chains must take proactive measures to ensure their long-term sustainability. This requires a holistic approach that balances economic growth with environmental stewardship and social responsibility, ensuring that food systems remain resilient and equitable for future generations. Embracing sustainable practices within global food chains will be essential for mitigating adverse effects while maximizing the benefits of globalization.

The key findings of the study revealed several important points. First, there is a negative relationship between digital technologies and SDG12, indicating that while these technologies can have a positive effect on sustainability, their overall impact on consumption and production is moderate but significant. This supports the H2 hypothesis, suggesting that the application of digital technologies may have unintended consequences for sustainable development. The study also found that increasing efficiency through digital tools can paradoxically lead to higher resource consumption.

The study also highlighted the challenges posed by digitalization in agriculture. As Kamble et al. pointed out, these include ensuring equal access to technology and data for all stakeholders, particularly smaller producers, as well as addressing concerns around data protection and cybersecurity in increasingly complex and interconnected food supply chains. Despite these challenges, the research confirmed a positive relationship between agricultural production and both sustainable consumption and the generation of municipal solid waste, validating the H1 and H3 hypotheses. This finding emphasizes the close connection between agricultural productivity and sustainability, as increased production brings both benefits and challenges for waste management.

Moreover, the study demonstrated that digital technologies can play a crucial role in reducing municipal solid waste by optimizing various processes such as production, distribution, and inventory management. This finding, which aligns with the research of Bahn et al., validates the H4 hypothesis, showing that digital tools can contribute to more effective waste management and, in turn, support the sustainability of food systems. However, the study also stressed the importance of considering the indirect environmental impacts of digital technologies, such as increased energy consumption and the generation of electronic waste. These factors must be managed carefully to ensure that the sustainability benefits of digitalization in agriculture are not undermined.

In conclusion, the study highlights the dual nature of digital technologies in the agricultural sector. While they offer significant potential to reduce waste, improve supply chain efficiency, and contribute to sustainable food production, they also present risks related to increased energy consumption and unequal access. As a result, a balanced and cautious approach to the implementation of these technologies is essential to ensure they contribute positively to the long-term sustainability of food systems.

IV. Discussion

The findings of this study indicate that sustainable consumption and production practices, in alignment with Sustainable Development Goal 12 (SDG12), have a negative influence on greenhouse gas (GHG) emissions from agriculture, supporting the H5 hypothesis (fig.3). This result highlights the critical role that sustainable practices can play in reducing agricultural emissions and mitigating environmental impact. These findings are consistent with the research of Dong et al., Agrawal et al., and Sharma et al., who emphasize that companies can enhance their operational efficiency using digital technologies while contributing to sustainability efforts, particularly in achieving SDG12. By improving efficiency and reducing GHG emissions, digital technologies can strengthen the sustainability of supply chains, making them more transparent and accountable. Furthermore, these technologies facilitate the monitoring and reporting of sustainable practices, thereby reinforcing sustainability goals across industries.

The study also confirmed the H6 hypothesis, revealing a positive relationship between agricultural production levels and GHG emissions. This suggests that as agricultural production increases, so too do emissions, underscoring the urgent need for more sustainable agricultural practices to reduce environmental degradation. Research by Kabange, Xu, Wang, and Ouyang supports these findings, showing that agriculture is a significant source of global GHG emissions due to activities like livestock fermentation and fertilizer use. However, modern agricultural practices, coupled with the adoption of digital technologies, can help mitigate these emissions by enhancing efficiency and sustainability.

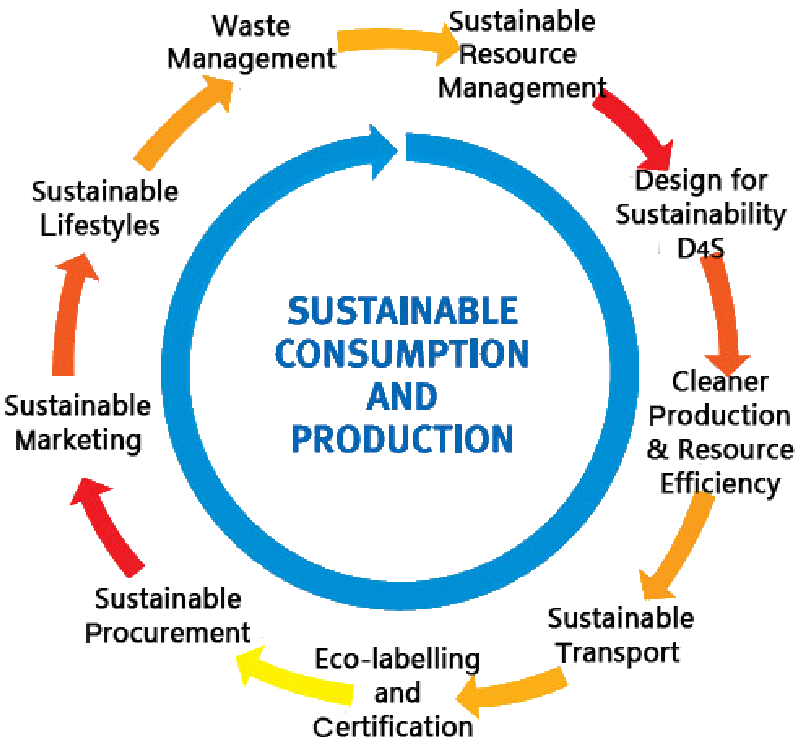

Figure 3: *Sustainable consumption & production*

Digital technologies, when implemented in agriculture, can provide significant advantages, including better resource management, real-time decision-making tools, and more sustainable farming practices. The results highlight the importance of promoting the adoption of these technologies across the food supply chain to meet sustainability goals. However, challenges remain, particularly regarding the equitable access to these technologies, especially for small- and medium-sized primary producers. Investments in digital infrastructure and education are necessary to support the transition to more efficient and sustainable agri-food systems.

The European Union (EU) is taking a proactive stance in promoting the digitalization of agriculture as part of its efforts to transition to more sustainable farming practices. The concept of the "fourth agricultural revolution" emphasizes the potential for digital technologies to transform agriculture radically. By integrating these technologies, production processes and resource management can be optimized, enhancing sustainability and resilience in the face of current and future challenges.

Digital technologies offer numerous benefits to agriculture, such as increased efficiency, reduced environmental impact, improved food quality, and higher incomes for producers. These tools also support more sustainable farming practices by reducing reliance on external inputs like pesticides and chemical fertilizers, while promoting the efficient use of natural resources. Additionally, they enhance access to agricultural information and services, particularly for rural producers, fostering greater transparency and efficiency across the entire food supply chain.

However, despite the advantages of digitalization, there are significant barriers to its widespread adoption. The high cost of advanced agricultural technologies can be prohibitive for primary producers, particularly in developing countries. Furthermore, a lack of training and resources to support the adoption of these technologies may exacerbate existing inequalities, creating a digital divide within the agricultural sector. Therefore, efforts to promote digitalization must address these challenges to ensure that the benefits of technology reach all stakeholders and contribute to the broader goal of sustainable development.

The challenges facing food systems are multifaceted and interconnected, reflecting the complexity and fragility of the global food chain. Issues such as population growth, competition for resources, climate change, dietary shifts, limited food access, unsustainable agricultural practices, and significant food waste contribute to the precariousness of food security. Rapid urbanization and population expansion place immense pressure on natural and agricultural resources, increasing the risks of food insecurity and environmental degradation. Climate change exacerbates these problems by directly impacting agricultural productivity and food accessibility for millions worldwide. Unsustainable farming methods further highlight the urgent need for reforms in agricultural and food supply chains to promote more equitable and sustainable production and consumption practices.

Reducing food waste and improving access to nutritious, sustainable food are essential to achieving future food security and sustainability. A sustainable food system benefits not only human health by ensuring access to safe, healthy food but also the environment and economies by protecting natural resources and supporting agricultural communities. As agriculture is a fundamental part of global economies and livelihoods, efficient and sustainable agricultural practices are critical to minimizing the sector’s environmental footprint. The current production and consumption patterns exacerbate climate change through increased greenhouse gas (GHG) emissions, highlighting the need for more environmentally friendly agricultural practices that protect future generations.

This paper emphasizes the role of digital technologies in optimizing resource use and reducing environmental impacts, fostering more sustainable consumption and production patterns. Additionally, these technologies can mitigate municipal waste by improving resource management. However, without appropriate regulations and sustainable resource management strategies, the use of these technologies could lead to resource overuse, necessitating a balanced approach to their implementation. To fully harness the benefits of digital technologies, legislative and policy frameworks must evolve in tandem with technological advancements, facilitating widespread adoption in agriculture beyond the food industry.

Understanding the needs and perspectives of primary producers is also essential to developing digital solutions that support a more efficient and inclusive transformation in agriculture. Despite the paper's efforts to explore the relationships between digital technologies, sustainable food production, GHG emissions, and municipal waste, certain limitations exist. The longitudinal nature of the study, while tracking trends over time, may have been influenced by contextual factors or unforeseen events. Additionally, the study focused primarily on the relationship between digital technologies and key aspects of food sustainability, such as crop and animal output, municipal waste, nitrogen and methane emissions, and Sustainable Development Goal 12 (SDG12). Future studies should consider broader aspects of food sustainability, including the social and economic impacts of technological shifts, such as employment in agricultural labor, market access for small producers, or the equitable distribution of technological benefits.

Another important area for future research is the unintended consequences of digitalization in agriculture. While the benefits of digital technologies are substantial, their potential negative impacts, such as the risk of digital exclusion or the concentration of economic power among large corporations, must also be examined. Future studies could investigate the specific effects of emerging digital technologies, including the Internet of Things (IoT), data analytics, and artificial intelligence (AI), on the sustainability of food systems. Such research would provide a more comprehensive understanding of how these technologies can be leveraged to enhance food system resilience while avoiding potential drawbacks.

ENVIRONMENTAL AND NATURAL CHALLENGES FACED BY DEPORTED PEOPLES IN THEIR NEW PLACES OF RESIDENCE

Sapiyat Tsutsulaeva

•

Kadyrov Chechen State University, RUSSIA
sapiyat_univ@mail.ru

Abstract

Deported populations often confront a wide array of environmental and natural challenges in their new places of residence, which can exacerbate the difficulties of displacement and resettlement. These challenges arise from being relocated to unfamiliar and often marginal areas with limited resources. Many of these regions may have poor soil quality, unreliable or limited access to clean water, and scarce arable land, making agricultural activities and food production difficult. Deported peoples may also face extreme climatic conditions such as heatwaves, cold spells, or heavy rainfall, depending on the region. Additionally, they often lack knowledge about the local ecosystems, which hinders their ability to utilize available resources effectively or protect themselves from environmental risks. Natural hazards, including droughts, floods, landslides, or even proximity to dangerous industrial sites, further threaten the deported populations' well-being. These groups often live in underdeveloped or impoverished regions that are vulnerable to environmental degradation, climate change impacts, and pollution. Combined with the socio-economic challenges they face, such as limited access to healthcare, education, and employment, these environmental and natural stressors significantly affect their capacity to adapt and rebuild their lives in new locations. The intersection of these environmental difficulties with social, economic, and political marginalization often leads to severe living conditions for deported peoples, undermining their long-term resilience and sustainability. Addressing these issues requires a holistic approach, including humanitarian aid, sustainable development practices, and policies that ensure deported communities have access to resources and the knowledge needed to thrive in their new environments.

Keywords: deportation, environmental challenges, climate adaptation, resource scarcity, natural hazards, livelihood vulnerability, ecosystem unfamiliarity, forced relocation

.

I. Introduction

Deportation is a complex and multifaceted issue that affects millions of people worldwide, often as a consequence of political, social, or economic instability. Individuals and families forced to leave their homes encounter not only the emotional and psychological toll of separation from their communities but also face numerous practical challenges in their new environments. The experience of being deported is compounded by the environmental and natural challenges they encounter, which can hinder their ability to adapt, integrate, and rebuild their lives.

When deported individuals arrive in their new places of residence, they frequently find themselves in regions that are unfamiliar, often marked by different climatic conditions, ecosystems, and resource availability. For many, this transition involves significant adaptation challenges, as they must navigate new agricultural practices, local flora and fauna, and different weather patterns. In many cases, they are relocated to marginal lands that suffer from environmental degradation, including poor soil quality, limited access to clean water, and inadequate infrastructure. These conditions make it difficult to secure reliable livelihoods, leading to food insecurity and heightened vulnerability.

Moreover, the environmental challenges faced by deported peoples are often exacerbated by natural hazards. Many are resettled in areas prone to floods, droughts, landslides, or other environmental risks, which can lead to loss of property and livelihoods. Such hazards not only threaten their immediate survival but also undermine their long-term prospects for stability and self-sufficiency. The lack of familiarity with the local environment can prevent deported individuals from effectively utilizing available resources or mitigating risks associated with their new surroundings.

The socio-economic challenges that deported peoples face further complicate their situation. Limited access to healthcare, education, and employment opportunities makes it difficult for them to achieve financial independence and social integration. In many instances, they may encounter discrimination or hostility from local populations, which can isolate them and hinder their efforts to adapt. The intersection of these social and environmental stressors creates a cycle of vulnerability that is hard to escape, as deported individuals struggle to secure a stable and sustainable future.

Understanding the environmental and natural challenges faced by deported populations is critical for informing policies and practices that promote their resilience and integration. This understanding must encompass not only the immediate needs of deported individuals but also the long-term sustainability of their new communities. Strategies must focus on providing humanitarian assistance, enhancing access to resources, and implementing sustainable development practices that take into account the unique environmental contexts of resettlement areas.

As the world grapples with increasing displacement due to conflict, climate change, and globalization, it is essential to prioritize the experiences of deported peoples and their interactions with the environments they inhabit. By addressing both the environmental and socio-economic dimensions of their challenges, we can work towards creating a more inclusive and supportive framework for the integration of deported communities. This introduction serves as a foundation for a deeper exploration of the various environmental and natural challenges faced by deported populations, as well as the policy implications and strategies needed to support their adaptation and well-being.

II. Methods

This study employs a multidisciplinary approach to analyze the influence of natural and climatic conditions on the integration process of deported peoples in special settlements. The methods used include a combination of historical analysis, geographical assessment, and qualitative case studies, drawing on both primary and secondary sources. The research is designed to provide a comprehensive understanding of how environmental factors shaped the experiences of these deported populations during their resettlement and adaptation.

1. Historical Document Analysis**:**

The primary method involves the analysis of archival records, government reports, and personal testimonies from deported individuals. Soviet-era documents, including official resettlement plans, labor assignments, and population censuses, provide crucial insights into the logistical and administrative aspects of the deportations. These records are cross-referenced with memoirs, letters, and oral histories of deportees to capture the lived experiences of those affected. By comparing official Soviet reports with personal narratives, the research aims to uncover the discrepancies between state policies and the realities faced by the deported peoples.

2. Geographical and Climatic Data Assessment**:**

A significant aspect of the research focuses on the geographical and climatic conditions of the regions where deportees were sent. This involves the use of historical climate data and geographic mapping to analyze the specific environmental challenges faced in different regions, such as Siberia, Kazakhstan, and the Russian Far East. Factors such as average temperatures, precipitation levels, and soil quality are examined to assess how they impacted agricultural productivity, labor requirements, and living conditions in the special settlements.

By mapping deportation locations and overlaying climatic data, the study seeks to correlate environmental conditions with integration outcomes. For example, settlements in extremely cold regions are compared with those in arid or semi-arid areas to identify patterns in survival rates, labor output, and community development.

3. Case Study Analysis**:**

The research also employs a case study approach to provide detailed accounts of specific deported communities and their adaptation processes. These case studies focus on deported groups such as Chechens, Crimean Tatars, and ethnic Germans, who were relocated to different regions under varying climatic conditions. Each case study looks at factors such as employment in local industries, agricultural success, mortality rates, and social cohesion to understand how natural environments influenced integration.

By using a comparative case study method, the research highlights how some groups managed to adapt more successfully than others, depending on the environmental conditions they encountered. These case studies are drawn from a variety of sources, including regional archives, local histories, and ethnographic studies.

4. Qualitative Interviews and Oral Histories**:**

In addition to archival research, the study incorporates qualitative interviews and oral histories where available. Interviews with descendants of deportees, as well as existing oral history projects, provide personal insights into the challenges faced by these populations and how they perceived the impact of climate on their daily lives. This qualitative data helps to capture the emotional and psychological aspects of integration that are not always reflected in official documents.

5. Thematic Analysis**:**

The data collected from archival research, climate analysis, case studies, and interviews are subjected to thematic analysis. Key themes such as "adaptation to harsh climates," "resource scarcity," "labor struggles," and "social cohesion under environmental stress" are identified and analyzed to explore the broader patterns of integration. This thematic approach helps to link the specific experiences of different deported groups with the overarching influence of environmental conditions.

6. Comparative Analysis**:**

Finally, a comparative analysis is conducted between different groups of deported peoples and the various regions to which they were relocated. This allows for the identification of factors that either facilitated or hindered the integration process across different natural and climatic contexts. Variables such as the type of labor, proximity to local populations, government support, and climatic severity are considered in comparing the experiences of deported communities.

Through this combination of methods, the study aims to offer a comprehensive and nuanced understanding of the role that natural and climatic conditions played in shaping the integration of deported peoples in special settlements.

III. Results

The deportation of Chechens, particularly during the tumultuous events of the 1940s, was marked by a profound and multifaceted influence of nature in their new environments. Forced to leave their ancestral lands, the deported Chechens were relocated to unfamiliar regions that posed significant challenges in terms of climate, landscape, vegetation, and access to natural resources. This drastic change impacted their traditional ways of life, especially in agriculture and animal husbandry, which had been central to their cultural identity and survival.

In their new areas of settlement across Russia, the Chechens encountered varying climates that dramatically affected their health and adaptability. The transition from one climatic zone to another introduced difficulties in acclimatizing to new temperatures and weather conditions. These changes in climate were not merely physical; they also had psychological and social implications, as the deported individuals struggled to navigate their new realities while mourning the loss of their homeland.

The new natural environments presented distinct challenges. For instance, the vegetation, soil fertility, and availability of pasture differed significantly from what the Chechens were accustomed to. Traditional Chechen agricultural practices, honed over generations, were often incompatible with the new conditions. The lack of familiar crops and suitable land for livestock exacerbated food insecurity and limited their ability to sustain their families. As a result, the relationship between the deported Chechens and their environment became strained, leading to a struggle for survival amid changing ecological contexts.

The interaction between people, development, and the environment is pivotal in understanding the broader implications of deportation. In the case of the Chechens, their development and growth were inextricably linked to the natural resources available in their new surroundings. The degradation of these resources, often compounded by environmental neglect and lack of support from the authorities, hindered their ability to thrive and integrate into their new communities.

This moment in history serves as a crucial reminder of the need for greater awareness and regulation of human activities concerning their environmental impacts. As we navigate the complexities of modernization and development, it is imperative to consider the long-term consequences of our actions on the natural world. The potential for irreparable damage to the environment is a pressing concern that demands urgent attention, particularly in light of the needs of vulnerable populations like the deported Chechens.

Protecting and improving the environment is essential for creating sustainable living conditions. Initiatives that focus on enhancing the natural landscape and promoting biodiversity can foster more favorable conditions for human habitation and recreation. In the context of the deported Chechens, addressing these environmental challenges is not only an ecological imperative but also a humanitarian one. By providing support and resources to help them adapt to their new environments, we can assist in their integration and promote their resilience.

Ultimately, the case of the deported Chechens illustrates the intricate relationship between people and their environment. Ensuring that future generations inherit a healthy and sustainable world is a responsibility we all share. As we reflect on the lessons from the past, it becomes clear that our collective actions today must prioritize environmental stewardship, especially for communities that have already endured significant hardships. The legacy of the deported Chechens reminds us that the health of our planet is intimately tied to the well-being of its inhabitants.

IV. Discussion

The deportation of Chechens during the 1940s serves as a poignant example of the complex interplay between human displacement and environmental challenges. The significant and multifaceted influence of the natural environment on deported Chechens highlights the broader implications of forced migration, particularly in relation to climate adaptation, resource management, and cultural identity.

Upon their relocation, deported Chechens faced a variety of environmental challenges that deeply affected their lives. The unfamiliar climates, often with extreme temperatures, posed immediate difficulties for adaptation. This climatic shift impacted their health, food security, and overall well-being. The Chechens were accustomed to specific agricultural practices and livestock management, which were not necessarily suited to the new areas they inhabited. This lack of compatibility forced them to abandon or radically alter their traditional ways of life, leading to food shortages and economic instability.

Moreover, the landscapes they were forced to navigate often presented additional barriers. The soil fertility varied significantly, which directly impacted their agricultural productivity. In many cases, the deported populations were settled in less fertile regions, which hindered their ability to cultivate crops that were staples in their traditional diet. This disconnect between their cultural practices and their new environmental realities illustrates how displacement can sever the bonds between communities and their land, leading to a loss of cultural identity and continuity.

Access to natural resources is another critical factor that shaped the experiences of deported Chechens. The abrupt transition to new environments not only affected the availability of resources but also introduced competition and conflict over these resources. In their original homeland, Chechens had established relationships with the land that facilitated sustainable use of resources. In contrast, the new regions often lacked the necessary support systems for resource management, exacerbating challenges related to water scarcity, land use, and food production.

Additionally, the socio-political dynamics of the regions where the Chechens were resettled often further complicated their access to resources. Discrimination and marginalization in these new communities could hinder their ability to integrate and secure necessary resources. The lack of supportive infrastructure and policies to assist deported individuals in their transition created an environment of vulnerability and instability, perpetuating cycles of poverty and displacement.

The cultural identity of the deported Chechens was significantly impacted by their environmental circumstances. The disconnection from their ancestral land and the subsequent changes in lifestyle challenged their sense of belonging and cultural practices. Traditional occupations such as agriculture and animal husbandry were not merely economic activities; they were integral to their cultural identity and community cohesion. The loss of these practices led to feelings of alienation and a diminished sense of community among deported populations.

However, resilience emerged as a key theme in the experiences of the deported Chechens. Despite the numerous challenges they faced, many individuals and families demonstrated remarkable adaptability and resourcefulness. Community networks formed to share knowledge, resources, and support, helping to create a sense of solidarity amidst adversity. This resilience underscores the importance of community and cultural continuity in navigating the complexities of forced displacement.

The discussion surrounding the experiences of deported Chechens highlights the need for policies that recognize the interplay between environmental factors and human displacement. Addressing these challenges requires a comprehensive approach that integrates humanitarian aid, sustainable development practices, and community support systems.

Policymakers should prioritize the following strategies:

1. Environmental Education and Adaptation: Providing deported populations with education about their new environments and training in sustainable agricultural practices can enhance their adaptability and resilience.
2. Resource Management and Accessibility: Ensuring equitable access to resources, including land and water, is crucial for the well-being of deported communities. Policies

should be implemented to support resource management initiatives that include the voices and needs of displaced populations.

3. Cultural Preservation: Recognizing the importance of cultural identity in the adaptation process, initiatives should be developed to help deported populations maintain their cultural practices and strengthen community ties. This could involve supporting traditional occupations and creating platforms for cultural expression.
4. Integrated Support Systems: Holistic approaches that integrate health, education, and economic support can help deported communities navigate the complexities of their new environments more effectively.

In conclusion, the experiences of deported Chechens illustrate the profound impact of environmental factors on the lives of displaced populations. By understanding these challenges and implementing supportive policies, we can foster resilience and help displaced communities adapt to their new realities while preserving their cultural identities. Addressing the environmental challenges associated with displacement is not only a matter of humanitarian concern but also a crucial step toward ensuring a more sustainable and equitable future for all.

The development of new lands by exiled Chechens in Kazakhstan and Central Asia was a complex and multifaceted process marked by a series of challenges and adaptations. Forced to leave their ancestral homes, the Chechens faced numerous obstacles as they sought to establish themselves in unfamiliar territories, where they needed to navigate new natural conditions and build sustainable livelihoods. This section explores the various aspects involved in this process, shedding light on the resilience and adaptability of the deported Chechen community.

Upon arriving in Kazakhstan and Central Asia, exiled Chechens were confronted with the necessity of adapting to new climatic and natural conditions. The state provided them with land plots to facilitate their settlement, which were essential for their agricultural and livestock-raising activities. However, adapting to the local environment involved more than just occupying new land. It required understanding the regional climate, seasonal variations, and the specific characteristics of local soils and pastures.

Chechens needed to familiarize themselves with the vegetation, local flora, and the agricultural practices suitable for their new environment. This adaptation was crucial for their survival and success as farmers and livestock herders. Given their traditional reliance on farming and animal husbandry, they required assistance and training to implement effective farming methods tailored to the climatic conditions of their new homes. This educational support was vital in ensuring that they could produce food and sustain their families in a new and often challenging environment.

In addition to environmental adaptation, the deported Chechens encountered significant infrastructure challenges in their new settlements. Many areas lacked essential services, including roads, schools, and medical facilities, which were necessary for the community's integration and development. The rebuilding and rehabilitation of infrastructure were critical to ensuring that the Chechens could access education, healthcare, and economic opportunities.

The state played a vital role in addressing these infrastructural deficits, and efforts were required to restore and improve the facilities needed for a functional community. The successful rehabilitation of infrastructure would not only support the immediate needs of the deported population but also contribute to their long-term development and integration into the broader societal fabric of Kazakhstan and Central Asia.

While developing new lands, it was equally important for the exiled Chechens to preserve their cultural traditions. The maintenance of cultural identity, including language, religion, rituals, and crafts, was essential for fostering a sense of community and belonging among the deported population. In the face of displacement, these cultural practices provided a vital connection to their heritage and history.

The integration of Chechen cultural traditions into the new social landscape was not only a matter of personal identity but also contributed to the cultural diversity of the regions where they settled. The mutual respect and brotherhood between Chechens, Ingush, and Kazakhs helped facilitate cultural exchanges and promote social cohesion, which was beneficial for all communities involved. The shared Islamic faith among these groups also fostered a sense of solidarity, as they navigated the challenges of their new environments together

The psychological impact of deportation and the challenges of adapting to new lands cannot be overlooked. Many deported Chechens experienced significant psychological distress due to the abrupt changes in their lives and the trauma of displacement. To cope with these changes, they needed psychological support and counseling to help them navigate their new reality.

The harsh conditions faced by all residents of Kazakhstan, combined with the trauma of displacement, created a complex environment where psychological support was crucial. Local communities, including Kazakhs, played an essential role in providing support to the deported Chechens, offering assistance and understanding during their difficult transition. The historical bonds between these groups, rooted in shared experiences and mutual respect, were vital for fostering resilience among the deported population.

The deportation of Chechens and their subsequent resettlement in Kazakhstan and Central Asia represents a significant chapter in the history of the region, yet it remains underexplored in Russian historiography. The ideological constraints and historical narratives surrounding the deportation have led to a lack of comprehensive research on this topic, creating what some scholars refer to as "blank spots" in the historical record.

Contemporary historiography faces the challenge of addressing these gaps and providing a nuanced understanding of the deportation experience. Scholars from various fields, including sociology, political science, and history, have begun to examine the complexities of Chechen deportation, shedding light on the social, political, and cultural dimensions of this historical event. The ongoing discourse surrounding the history of the Chechen people and their experiences during deportation is essential for recognizing the profound impact of these events on their identity and cultural heritage.

The development of new lands by exiled Chechens in Kazakhstan and Central Asia was marked by a multitude of challenges, including adaptation to new environmental conditions, infrastructural rehabilitation, cultural preservation, and psychological adjustment. Despite the difficulties they faced, the deported Chechens exhibited remarkable resilience and adaptability as they sought to rebuild their lives. The historical context of their deportation and settlement underscores the importance of continued research and recognition of their experiences, paving the way for a deeper understanding of their cultural identity and the impact of displacement on communities.

Abstract

This article examines the financing tools for environmental projects that ensure an effective flow and transfer of capital between global investors. All this is aimed at expanding the use of "green" technologies, strengthening "green" culture and environmental sustainability, as well as solving the problem of climate change during the global energy transition. The study noted that improving the energy efficiency of countries and economies will be crucial in order to meet climate ambitions, ensure growth and improve well-being, especially to achieve the goal in terms of carbon emissions in the long term. Energy efficiency in the financial industry is considered an attractive investment, as it generates new dynamics to accelerate and expand private financing of investments and make these investments more effective for investors. The publication lists various instruments for financing environmental projects. The distribution of funds distributed among various programs within the framework of the EU's next-generation economic recovery program for the period from 2020 to 2027 and the Use of green bond programs in Europe in 2014-2021 by industry are also presented in the form of graphs. Financing instruments for environmental projects play a key role in promoting sustainable development and reducing negative environmental impacts. In recent years, there has been a growing interest in "green" financing, which includes various financial instruments aimed at supporting environmentally friendly technologies and projects. Crowdfunding as an alternative source of financing: Crowdfunding allows you to attract an unlimited number of investors with different levels of financial literacy and accessibility, which makes it attractive for environmental projects. Green bonds and loans are important tools for financing the transition to a green economy by providing extra-budgetary sources of financing.

Keywords: capital movement, the "green" transition, energy efficiency, safe and reliable economic justification, Innovative tools, financing of environmental projects, global energy

I. Introduction

Investments in energy efficiency often lead to high transaction costs because projects are small and not aggregated enough to attract investors. These types of investments, such as building overhauls, have a long payback period, and investors fear that the savings achieved will not justify the cost of energy upgrades. However, it is becoming increasingly clear that the risks associated with them are lower than the level perceived by the market.

To convince investors that energy efficiency projects in general have a safe and reliable economic justification, and to help banks and other financial institutions easily understand and assess all the risks and opportunities associated with a particular project. There is an urgent need for technical and legal standardization at all stages of the investment value chain in order to simplify transactions and increase the trust of financial institutions.

The lack of standardization of projects hinders the securitization of energy-efficient assets in the capital markets. It is usually expected that the cost of energy efficiency investments will be offset solely by reducing energy bills, but it is becoming increasingly clear that the benefits are non-energy in nature, including improving comfort and health parameters in buildings, increasing the cost of the building itself, increasing the cost. A lower probability of default on mortgages and lower rates for attracting tenants or vacant property play a key role in deciding whether to invest in this area. Therefore, there are tangible financial and economic incentives to encourage financial institutions to invest more in energy efficiency. In Italy, innovative tools proven by industry are aimed at encouraging additional investments in energy efficiency initiatives, especially those conducted by small and medium-sized businesses.

II. Methods and materials

The research uses information data, as well as methods of theoretical research, namely: monographic.

Financing environmental projects in the energy sector is an important aspect for achieving sustainable development and reducing negative environmental impacts. In recent years, there has been an increase in interest in various financial instruments that can support the implementation of such projects.

III. Results and discussion

Green bonds and other debt instruments. The use of green bonds and other debt instruments such as corporate bonds, project bonds and financial green bonds to mobilize private capital. The use of project financing for large investment projects in the field of renewable energy allows for better risk management and reduction of agency conflicts. Guarantee schemes and tax benefits. Development of green loan guarantee schemes to reduce credit risks and the use of tax incentives to increase the profitability of green projects.

Funds and subsidies. Creation of funds, such as the Environmental Protection and Energy Efficiency Fund (EPEEF) in Croatia, to finance environmental and energy projects through soft loans, subsidies and grants. Legal mechanisms and digital green industrial mortgages. Development of legal mechanisms, such as digital green industrial mortgages, to attract investments in environmental projects in the fuel and energy sector.

Risk and profitability management. An effective policy should simultaneously take into account the risks and returns on investment in order to attract private capital to renewable energy projects. Financing environmental projects in the energy sector requires an integrated approach, including the use of various financial instruments such as green bonds, project financing, tax incentives and guarantee schemes. Both state and non-state financial institutions play an important role. Effective legal and policy mechanisms aimed at managing risks and profitability are also key to successfully attracting investments in this area.

Green bonds: the energy sector benefits the most. Use of procceds from green bonds in Europe 2014-2021, by industry (in billion U.S. dollars) (Fig. 1).

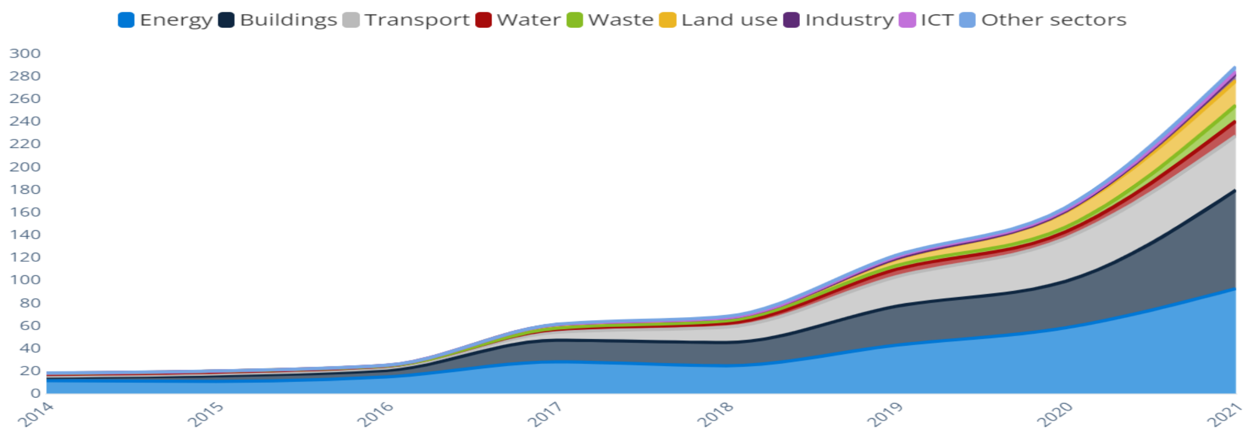

Figure 1: *Green bonds: the energy sector benefits the most. Use of procceds from green bonds in Europe 2014-2021, by industry (in billion U.S. dollars)*
Source: https://www.statista.com/topics/6233/green-bonds-in-europe/#topicOverview [103]

Green bonds, also called climate bonds, indicate that investors are interested in sustainable development. Environmental degradation and climate change pose serious physical and transitional risks to financial stability, such as business disruptions, asset destruction, reduced value of unused assets and increased insurance costs. Investors recognize the potential of sustainable financing and launch new and restructure old financial products to identify opportunities, mitigate risks, or align values. In Europe, the most common type of green bond issuers were financial corporations, which accounted for a third of all green bonds issued in Europe in 2022 [1-11].

The role of financing is extremely important to fill the deficit in order to develop Indonesia's green economy. The government has released an innovative financial instrument for financing the state budget (APBN) with the help of "green" sukuk. In 2019, the government also established the Environmental Fund Management Agency (BPDLH) to improve the quality of green financing.

Singapore has allocated 2.1 billion Singapore dollars from proceeds from the sale of bonds maturing in 50 years to cover the cost of building two subway lines. This bon was presented as part of the Singapore Green Bon program and is part of a larger government strategy to finance environmental projects. The construction costs of MRT Jurong and MRT Pulau include 1.7 billion Singapore dollars due to green bonds issued in 2022 and 0.4 billion Singapore dollars due to green bonds issued in September 2023, where trade turnover increased 1.4 times to 2.8 billion Singapore dollars.

Since 2027, the construction of the MRT in the Jurong area and on Penang Island has been carried out in stages. The opening of two metro lines will help reduce carbon dioxide emissions by more than 100,000 tons per year, which is equivalent to eliminating the use of 22,000 trains on motorways. He notes an 81 percent reduction in CO2 emissions. A $2.1 billion green bond fund has been allocated for the construction of a highway across Jurong Island [12].

A total of $ 2.1 billion raised through green bonds issued by the Government has been allocated for the construction of the Jurong Area Line (JRL) and the Inter-Island Line (CRL), which are currently under construction. Both routes support the basic principles of the "sustainable lifestyle" of the Singapore Green Plan 2030. According to the September 25 report of the Ministry of Finance (MOF), the funds were distributed in 2023. As part of this phase, it is planned that by 2030, 75 % of passengers will use public transport during peak hours compared to private transport. According to the latest data, this figure is about 64 %.

This is a serious effort to achieve the ambitious goal of significantly reducing carbon dioxide emissions by land transport in absolute terms, in line with Singapore's goal of zero carbon dioxide emissions by 2050. Experts estimate that routes in the Jurong area and between the islands will provide total carbon dioxide emissions savings equivalent to the use of at least 22,000 vehicles. It is expected that the remaining funds from the newly opened part of the program will be fully allocated by the end of the 2025 fiscal year. Today, Singapore's green bond system remains a key element of Singapore's efforts to channel investments into projects that will contribute to sustainable development efforts.

By 2030, the Singapore government will issue green bonds worth up to $35 billion to finance public sector green infrastructure projects. The relevant categories included renewable energy sources, energy efficiency, green construction, environmentally friendly transport and sustainable management of water supply and wastewater. These projects are expected to help Singapore transition to a low-carbon economy, contributing to the achievement of the climate and environmental goals set by the Government. As a leading energy transition company, Pertamina is committed to achieving zero emissions by 2060 by continuing to support programs that directly impact the achievement of the Sustainable Development Goals (SDGs). All these efforts are consistent with the principles of environmental, social and managerial responsibility (ESG) in all business lines and operations of Pertamina.

The Government has put into effect the tools of the Federal Communications Commission to finance environmental protection measures in forests. A non—market financial instrument, the Forest Conservation Certificate (FCC), is used to finance forest conservation and environmental protection activities. The FCC is one of the mechanisms developed by the Malaysian Forest Fund (MFF) since 2022 as part of the Financial REDD Plus (RFF) program.

The Forest Conservation Certificate (FCC) issued by the Malaysian Forest Fund (MFF) is a financial instrument that is not used in the market to finance environmental protection measures and initiatives for sustainable forest management, as well as to protect the environment.

Since 2022, Malaysia has begun work on the creation of innovative financial instruments based on RFF. Thus, the RFF mechanism is a one—step transformation that provides a new paradigm in financing environmental activities and nature-based solutions, recognizing the important role of the public-private partnership structure.

Breakdown of funds allocated among different programs in the NextGenerationEU economic recovery package from 2020 to 2027(in billion Euros) (Fig. 2).

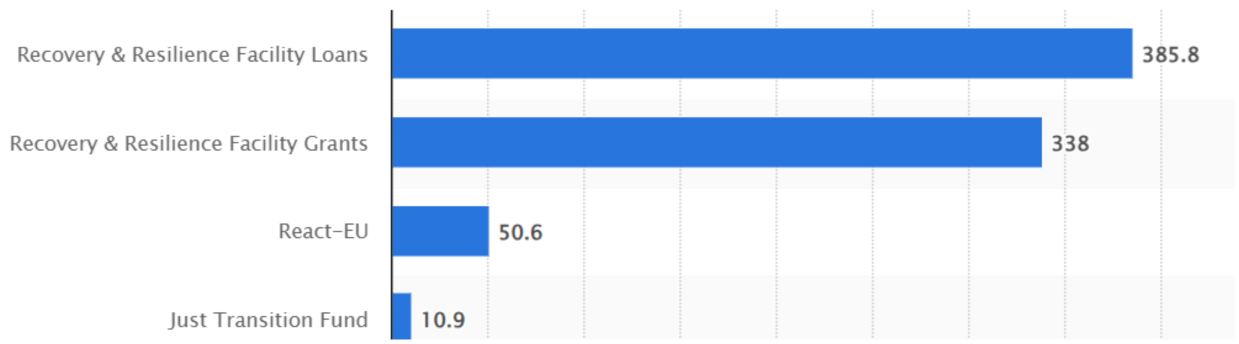

Figure 2: *Breakdown of funds allocated among different programs in the NextGenerationEU economic recovery package from 2020 to 2027(in billion Euros)*
Source: https://www.statista.com/statistics/1366824/next-generation-eu-funds-allocation/

From Fig. 2 it can be seen, the largest share in the package is occupied by the Recovery and Sustainability Fund, which provides loans and grants to participating countries to invest in projects that promote the growth of "green" industries, stimulate the digitalization of the economies of participating countries, as well as to invest in social, economic and institutional development. Other programs included in the NextGenEU package range from the Fair Transition

Fund, which aims to support regions most affected by the transition to a green economy, to rescEU, which invests in supplies to respond to humanitarian crises.

About 45 percent of the total funds of the Recovery and Sustainability Fund (RRF) were allocated to green transition projects (not including projects in which the element of green transition is combined with one of the other categories). Member States such as Denmark, Poland, Belgium and Ireland have allocated most of their funds to this category. On the other hand, Greece, Slovakia, Latvia and Cyprus have allocated more funds to projects focused on social, economic and institutional development. Germany has allocated the largest share of RRF funds to digital transformation — about 37 percent of the total.

IV. Conclusion

Financing instruments for environmental projects play a key role in promoting sustainable development and reducing negative environmental impacts. In recent years, there has been a growing interest in "green" financing, which includes various financial instruments aimed at supporting environmentally friendly technologies and projects.

Crowdfunding as an alternative source of financing: Crowdfunding allows you to attract an unlimited number of investors with different levels of financial literacy and accessibility, which makes it attractive for environmental projects.

Green bonds and loans are important tools for financing the transition to a green economy by providing extra-budgetary sources of financing.

Studies were carried out on Pirallahi, Gurgan-deniz, Khali, Chilov, Janub, Janub-2, Azi Aslanov, Palchig-Pilpilesi, Neft Dashlari, Gunashli, Chirag, Azeri and Kapaz structures in the Absheron-Balkan oil and gas-bearing zone. Paleogene-Quaternary sediments are represented in the section of the sedimentary cover of the Absheron-Balkan zone. The industrially productive oil and gas deposits discovered in this zone are related to the suites of the lower and upper stages of the Productive series (Pliocene).

The changes risk of the total thicknesses and sand content of the suites of Productive series in the structures of the study area were analyzed in the direction of four anticlinal zones.

To determine the change risk of thickness and sand content of individual suites of the PS and the phase zonation of hydrocarbons corresponding graphs were constructed and analyzed. The graphs are constructed based on average values of thickness and sand content.

According to the conducted analyses, the thickness and sand content of the suites of the lower and upper stages of the PS on the Pirallahi-Janub-2, Khali-Neft Dashlari, Gunashli-Kapaz anticlinal zones are increas from the northwest to the southeast along the northeast and southwest limbs. The characteristics of the thickness changes risk of the PS suites show that the tectonic movements and the relief of the basin bottom play a key role in the thickness distribution. Based on the change of sand content in the study area, it can be noted that the paleogeographical conditions in the basin during the formation of PS sediments were quite favorable.

The Kapaz structure, located at the southeastern end of the Gunashli-Kapaz anticlinal zone, is similar in geological structure with other folds of the anticlinal zone where it is located. It can be noted that the GaS, PK, PKS, Balakhani suites with gas-condensate-oil bearing in the adjacent fields are also highly promising here. In the Azeri field, which is located in this anticlinal zone, the PKS suite of the Productive series is gas-condensate bearing. The PK and GaS are oil-gas-condensate-bearing in the neighboring Chirag and Gunashli fields, so, they are also can be promising here.

The complexity level of the folds noted here is different. İt is play a fundamental role in the distribution of oil and gas fields. İt should be noted that longitudinal faults play a key role in the distribution of hydrocarbon accumulations in the fields of Absheron oil and gas region. Due to influence of the transverse faults folds are placed in a stepped form. İt is lead to reshape the oil fields in Pliocene sediments. Regarding the formation of oil and gas deposits, it should be noted that this process is formed as a result of the alternating activity of vertical and lateral migrations. Therefore, in the chain-arranged ascents within the mentioned zone, in the southeast-northwest direction, so, the differential entrapment of oil and gas along up dip is justified. That is, along the Pirallahi-Janub-2 anticlinal zone, gas-condensate deposits are replaced by oil-gas, in turn, the oil-gas deposits are replaced by oil deposits in the southeast-northwest direction. The lower suites of the PS on the Gunashli-Kapaz anticlinal zone are mainly characterized by gas-condensate, and the upper suites are mainly characterized by the presence of oil-gas accumulations.

Keywords: deposits, gas-condensate, suites, anticlinal zone, fault, vertical and lateral migrations, subduction zone, differential entrapment

I. İntroduction

The Absheron-Balkan structural megasaddle, which is a structural element of the South Caspian depression, geodynamically is a structural-tectonic expression of a non-classical subduction zone, as well as at the same time forms the north-northeast slope of the South Caspian depression [9, 10]. The Absheron-Balkan oil and gas-bearing zone includes Pirallahi, Gurgan-deniz, Janub, Janub-2, Khali, Chilov Island, A. Aslanov, Palchig Pilpilesi, Neft Dashlari, Oguz, Gunashli, Chirag, Azeri and Kapaz fields (Fig. 1) [3].

12 of the 14 structures located in the Absheron-Balkan folding zone are considered deposits that they are being developed. Oil, gas and gas-condensate system deposits here belong to both the upper (Surakhani-Fasila suites) and lower (PKC, PKS, KS, PK, GaS) stages of the Productive series (PS) sediments.

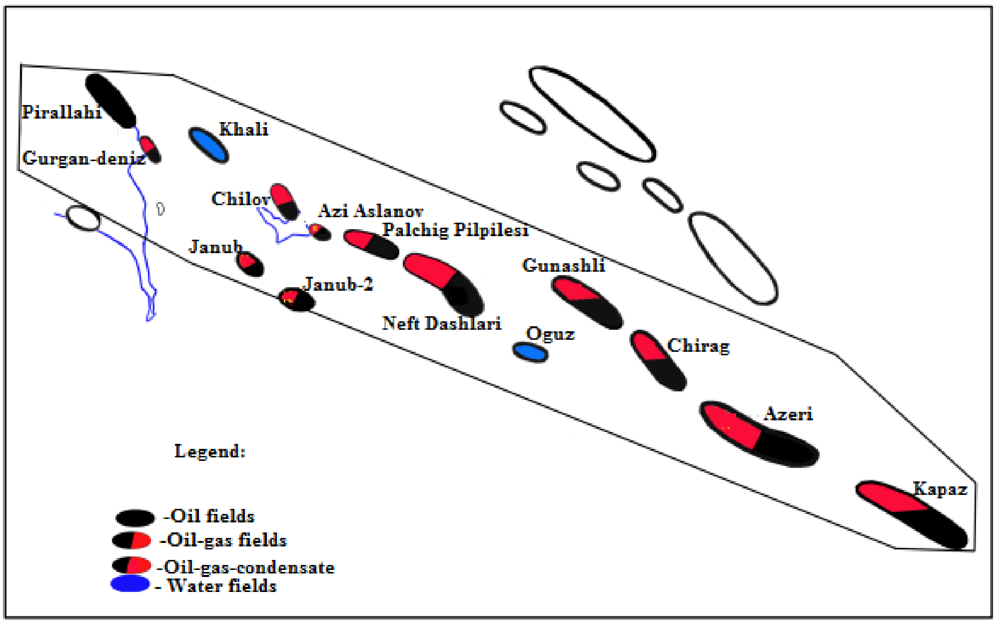

Figure 1: *Overview map of the structures*

Since the 80s of the last century, complex geological (drilling, seismoacoustic profiling, engineering-geological studies) work has been started in the abyssal exploration areas of the Caspian Sea, including the Gunashli, Chirag, Azeri, and Kapaz areas. As a result of structural-prospecting and prospecting-reconnaissance drilling, the Pirallahi Island, Gurgan, Palchiğ Pilpilesi and Neft dashlari fields were discovered.

The sediments involved in the geological structure of the areas belonging to the Absheron-Balkan zone cover a wide stratigraphic interval (from the Paleogene (₽) to the Quaternary (Q)).

Rich oil and gas deposits discovered in the Apsheron zone are associated with Pliocene sediments. In the Apsheron-Balkan oil-gas-bearing zone, studies were carried out on the Pirallahi, Gurgan-deniz, Khali, Chilov, Janub, Janub-2, Azi Aslanov, Palchig-Pilpilesi, Oguz, Neft Dashlari, Gunashli, Chirag, Azeri and Kapaz structures [12-14].

In general, in certain periods in the study area, mainly at the end of the Lower Pliocene, the occurrence of uplift affected either partial or complete washing out of the upper PS sediments, as well as the change of their lithological composition, leading to pinching out of a number of layers and, therefore, restrictions in terms of oil and gas prospects.

II. Method

The changes of total thickness and sand content of PS sediments in the structures of the study 244 wells were included in the interpretation project. 5 in Pirallahi, 7 in Gurgan-deniz, 5 in Khali, 6 in Chilov, 9 in Janub and 3 in Janub-2 fields, 5 in A. Aslanov, 4 in Palchig-Pilpilesi, 19 in Neft Dashlari, 2 in Oguz areas, 17 wells in the Gunashli, 4 in the Chirag, 3 in the Azeri, as well as 5 in the Kapaz field were studies. The results of the geophysical studies conducted in the wells were investigated [13].

In the study area, models characterizing the thickness and sand content of individual anticlinal zones were drawn up. The models are constructed by using of Surfer program.

III. Discussion

The thickness and sand content of the horizons and suites of the PS sediments in separate anticlinal zones are traced in the study area. As is known, the analysis of changes in the petrophysical properties of rocks along the area and depth allows to determine their reservoir properties change in that direction and to relatively objectively assess both the fluid capacity and oil-gas prospects of natural reservoirs [8]. For this purpose, in order to determine the thickness and sand content of the individual suites of the PS in the Pirallahi, Gurgan-deniz, Janub, Janub-2, Chilov, Palchig Pilpilesi, Neft Dashlari, Gunashli, Azeri, Chirag, Kapaz fields and to determine the phase zonation of hydrocarbons, the corresponding graphs were constructed and analyzed. The graphs are constructed based on average values of thickness and sand content values (Fig.2).

According to the graph the thickness of the Pre-Kirmaki sandy (PKS) suite is fluctate between 41-54 m in the Pirallahi, 34-54 m in the Gurgan-deniz, while 57-60 m in the Janub fields. It varies up to 52 m in the Janub-2 field located along the Pirallahi-Gurgan-deniz-Janub-Janub-2 anticlinal zone. The sand content of PKS varies between 27-58% in the Pirallahi, 25-78% in the Gurgan-deniz, 33-35% in the Janub and up to 31% in the Janub-2 fields.

The thickness of the Kirmaki suite (KS) varies between 234-292 m in the Pirallahi, 285-566 m in the Gurgan-deniz, 226-243 m in the Janub fields, while up to 230 m in the Janub-2 area. The sand content of the KS varies between 14-32% in the Pirallahi, 16-31% in the Gurgan-deniz, 9-15% in the Janub areas, and up to 38% in the Janub-2 area.

The thickness of the Pre-Kirmaki (PK) suite ranges from 22 to 90 m in the Pirallahi, from 130 to 173 m in the Gurgan-deniz, from 127 to 133 m in the Janub areas, while up to 128 m in the Janub-2 area. The sand content of the PK suite varies between 36-62% in the Pirallahi, 27-65% in the Gurgan-deniz, 60-92% in the Janub areas, and up to 94% in the Janub-2 area. The uncovered thickness of the Gala suite (GaS) varies between 135-333 m in the Gurgan-deniz, 143-379 m in the Janub areas, while up to 120 m in the Janub-2 area. The sand content of GaS varies between 8-19% in the Gurgan-deniz, 8-10% in the Janub, and up to 75% in the Janub-2 areas.

According to the graph constructed along the Chilov-A.Aslanov-Palchig Pilpilesi-Neft Dashlari anticlinal zone [12], the thickness of the PKS suite in the southwest limb of the structures is noted as following: 26-45 m in the Chilov area, up to 38 m in the A.Aslanov area, and between 28-38 m in the Palchig Pilpilesi, it varies between 26-30 m in the Neft Dashlari, and up to 49 m in the Oguz areas. The sand content of the suite is consists 16-50% in the Chilov, 24% in the A. Aslanov areas, between 16-29% in the Palchiq Pilpilesi, 23-75% in the Neft Dashlari, and 55% in the Oguz areas is observed (Fig. 3).

The thickness of the KS varies between 223-504 m in the Chilov, up to 364 m in the H. Aslanov, 276-372 m in the Palchig Pilpilesi, 280-379 m in the Neft Dashlari, and up to 258 m in the Oguz areas. The sand content of KS varies between 4-20% in the Chilov, 3% in the A.Aslanov areas. İt is fluctate between 3-8% in the Palchig Pilpilasi, 2-3% in the Neft Dashlari areas, while up to 2% in the Oguz area.

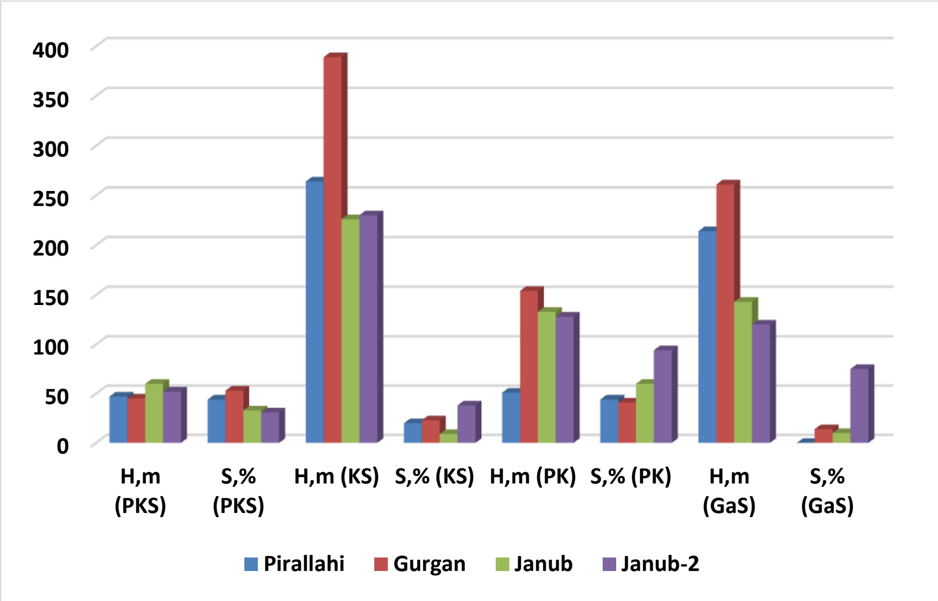

Figure 2: *The thickness and sand content of suites of the PS sediments along the Pirallahi-Gurgan-deniz-Janub-Janub-2 anticlinal zone*

The thickness of PK suite varies between 93-114 m in the Cilov area, while up to 92 m in the A.Aslanov area. It represented by 80-117 m section in the Palchig Pilpilesi area, while 35-89 m in the Neft Dashlari field, and up to 116 m in the Oguz area. Sand content of PK 24-27% along the Chilov area is observed, while 35% along the A.Aslanov area. İt is consists of 25-39% in the Palchig Pilpilesi, 34-53% in the Neft Dashlari areas, and 94% along the Oguz area is noted.

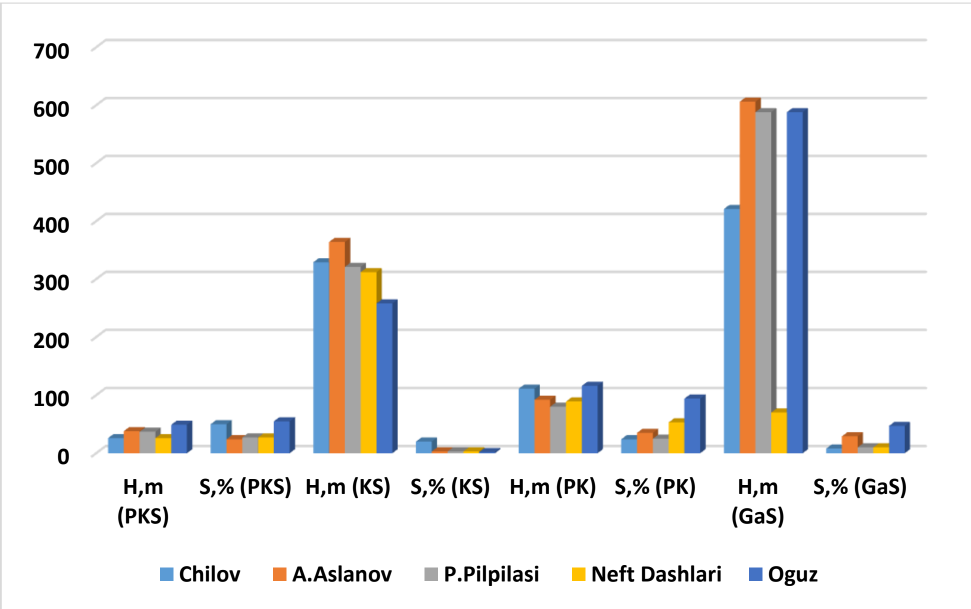

Figure 3: *The thickness and sand content of suites of the PS sediments along the Chilov-A.Aslanov-Palchig Pilpilesi-Neft Dashlari*

The exposed thickness of GaS ranges from 187-498 m in the Chilov area, while up to 606 m in the A.Aslanov field. İt is 394-588 m in the Palchiq Pilpilesi area, and up to 70 m in the Neft Dashlari area. The Oguz area is represented up to 588 m by the GaS sediments. The sand content of GaS ranges from 8-16% in the Chilov area, it is 29% in the A.Aslanov field. The Palchiq Pilpilesi and Neft Dashlari field sections are represented by 10-27% and 10% respectivly. İt is up to 47% in the Oguz area.

According to the longitudinal correlation scheme in the northwest limb direction, the thickness of the PKS is up to 38 m in the Khali area, while 26-38 m in the Chilov area. İt is up to 29 m in the A. Aslanov area. The Palchiq Pilpilesi and the Neft Dashlari areas are represented by the PKS sediments of 27-39 m and 25-46 m correspondingly. The sand content of PKS suite is 42% in the Khali area, 27-42% in the Chilov area, 83% in the A. Aslanov area, 12-22% in the Palchig Pilpilesi area, while 88-100% in the Neft Darshali [11, 12].

The thickness of KS ranges up to 274 m in the Khali area, between 325-351 m in the Chilov, while up to 329 m in the A. Aslanov area. İt is 271-357 m in the Palchig Pilpilesi and 250-372 m in the Neft Dashlari areas. Sand content of PK suite is 24% alomg the Khali, between 2-8% in the Chilov, 22% in the A. Aslanov areas is observed. 2-13% and 2-3% along the P. Pilpilesi and the Neft Dashlari areas is noted, respectivly.

The thickness of PK suite varies up to 72 m in the Khali area, between 112-131 m in the Chilov area, while up to 72 m in the A. Aslanov area is observed. Between 78-133 m and 69-99 m in the Palchig Pilpilesi and the Neft Dashlari areas is noted, correspondingly. The sand content of the PK suite is noted as following: 69% in the Khali, 19-55% in the Chilov, 50% in the A. Aslanov, 7-13% on the P. Pilpilesi area, 33-56% along the Neft Dashlari (Fig.4).

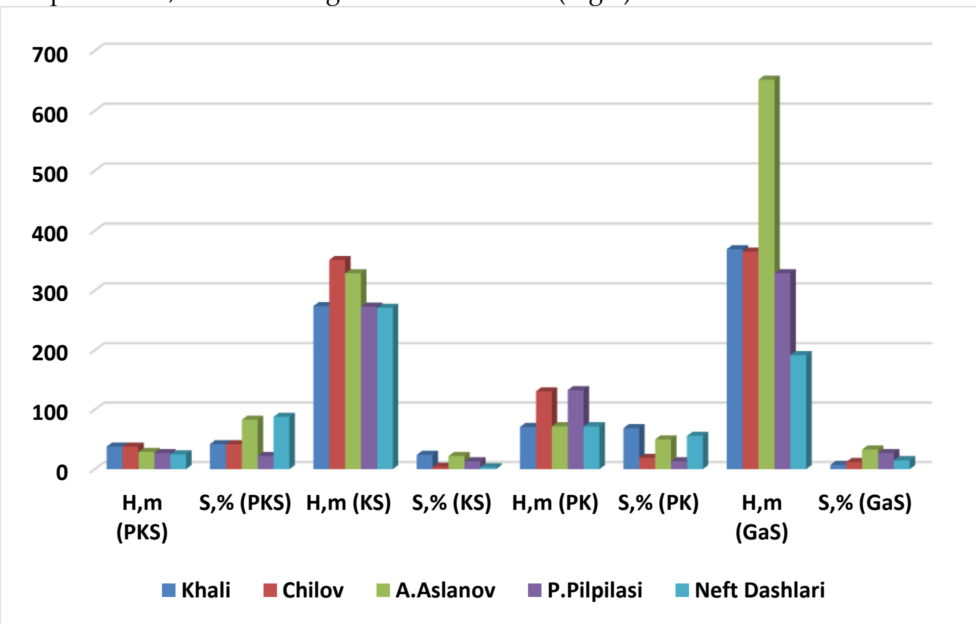

Figure 4: *The thickness and sand content of suites of the PS sediments along fields*

The uncovered thickness of GaS varies up to 369 m in the Khali, between 282-445 m in the Chilov, up to 652 m in the A. Aslanov, between 329-470 m in the Palchig Pilpilesi areas, and between 134-192 m in the Neft Dashlari field. The sand content of GaS suite is 7% in the Khali, 12-15% in the Chilov, 33% in the A. Aslanov, 13-29% in the P. Pilpilesi areas, while 15-28% in the Neft Dashlari area.

According to the longitudinal correlation scheme (Fig. 5) in the direction of the northeast limbs of the Guneshli, Chirag, Azeri, Kapaz structures according to the top of PKC suite the thickness of SuS varies between 1105-1385 m in the Gunashli, 888-968 m in the Chirag, 920-1028 m in the Azeri, and up to 1430 m in the Kapaz areas. The sand content of SuS varies up to 1-2% along the Gunashli, 3% - Chirag, 2-4% - Azeri, and up to 2% in the Kapaz areas is noted.

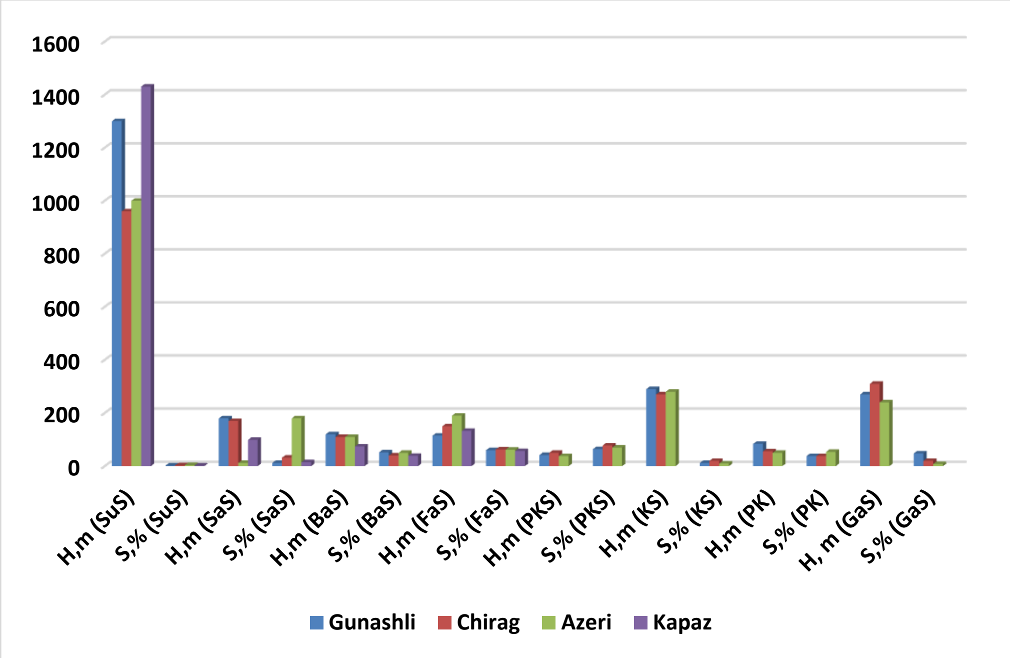

Figure 5: *The thickness and sand content of suites of the PS sediments along the northeast limbs of the structures*

The thickness of the horizon IV of SaS varies between 143-181 m in the Gunashli area. İt is 118-174 m in the Chirag, 98-99 m in the Azeri, and up to 99 m in the Kapaz areas. The sand content of the horizon IV of SuS varies as following: between 7-13% in the Guneshli area, 19-33% -in the Chirag, 8-13%- in the Azeri, and up to 15% in the Kapaz areas.

The thickness of the horizon V of the BaS ranges 74-148 m in the Gunashli, up to 100 m in the Chirag, 180-185 m in the Azeri, and up to 92 m in the Kapaz areas. The sand content ranges as following: 16% -in the Guneshli, 17-18% -in the Chirag, 21-23% -in the Azeri, and up to 17% in the Kapaz areas is abserved.

The thickness of the BaS (VI horizon) varies between 101-141 m in the Gunashli, 101-125 m in the Chirag, 109-117 m in the Azeri areas, and up to 137 m in the Kapaz field. The sand content of the BaS horizon VI is 24% in the Gunashli, 22% in the Chirag, 18-20% in the Azeri, and up to 17% in the Kepaz areas.

The thickness of the horizon VII BaS varies along following: 109-123 m, 99-117 m, 103-112 m and up to 74 m in the Gunashli area, Chirag Azeri and Kapaz areas, correspodingly. The sand content between 52-53%, 30-40%, 31-50% and up to 39% in the Gunashli, Chirag, Azeri, Kapaz areas is observed.

The thickness of the BaS (horizon VIII) varies between 109-119 m in the Gunashli area. İs 146-165 m in the Chirag, 118-127 m in the Azeri, and up to 73 m in the Kapaz areas. The sand content of horizon VIII varies between 18-30%, 18-35%, 26-43% and up to 28% in the Gunashli, Chirag, Azeri and Kapaz area, respectively.

The thickness of the BaS IX horizon section ranges from 120-148 m in the Gunashli field. 112-113 m in the Chirag, 111-130 m in the Azeri, and up to 90 m in the Kapaz areas. The sand content of the horizon IX consists 16-50%,14-34%, 18-22%, and up to 18% along the Guneshli, Chirag, Azeri, and Kapaz areas, respectively.

The thickness of the X horizon of BaS is identifid of 46-104 m in the Guneshli area, 92-95 m in the Chira, 97-105 m in the Azeri, and up to 68 m in the Kapaz areas. The amount of sand along the section of horizon X varies between 18-34% in the Guneshli, 27-48% -in the Chirag, 30-44% -in the Azeri, and up to 33% in the Kapaz areas is identified.

The thickness of Fasila suite is concidered as following sequentially: in Gunashli area -110-115 m, in Chirag- 132-153 m, in Azeri area- 135-196 m, up to 133m in Kepaz. The sand content of suite varies between 53-63%, 63%, 61-63% and up to 57% in the Gunashli, in the Chirag, in the Azeri, in the Kapaz areas, respectively.

The thickness of the sediment of PKS suite varies from 34 to 43 m in the Gunashli area. İt is consists 45-50 m in the Chirag, and varies from 37 to 38 m in the Azeri field. The sand content of the suite varies 62-65%- in the Guneshli, 68-78% -in the Chirag, while between 46-71% in the Azeri areas.

The thickness of KS varies between 268-293 m in the Guneshli area, between 242-271 m in the Chirag area, and between 263-283 m in the Azeri area. The sand content of the suite varies from 12% in the Gunashli, 16-20% in the Chirag, and 9-12% in the Azeri areas.

The thickness of PK suite ranges from 69 to 85 m in the Guneshli area. İn the Chirag and in the Azeri areas is represented by 45-57 m and 36-53 m thick section. The sand content of the suite is 33-38%, 35-39%, 40-54% in Guneshli, in Chirag, and in Azeri areas, correspondingly.

The thickness of the GaS varies between 252-279 m in the Gunashli, 291-316 m in the Chirag, and 240-318 m (opened) in the Azeri fields. The sand content of GaS about 28-49% in the Gunashli area is noted. İt is 4-23% in the Chirag, and 5-8% in the Azeri areas.

According to the longitudinal correlation scheme (Fig.6) in the SW limb direction in the Gunashli, Chirag, Azeri, Kapaz areas according to the top of FaS the thickness of SuS 950-1158 m in the Gunashli, 1074-1108 m in the Chirag, up to 951 m in the Azeri, and up to 1397 m in the Kapaz areas is found. Sand content of section 1-4%, 2-3%, 3% and 2% in Guneshli, in Chirag, in Azeri, in Kapaz areas is noted, relatively.

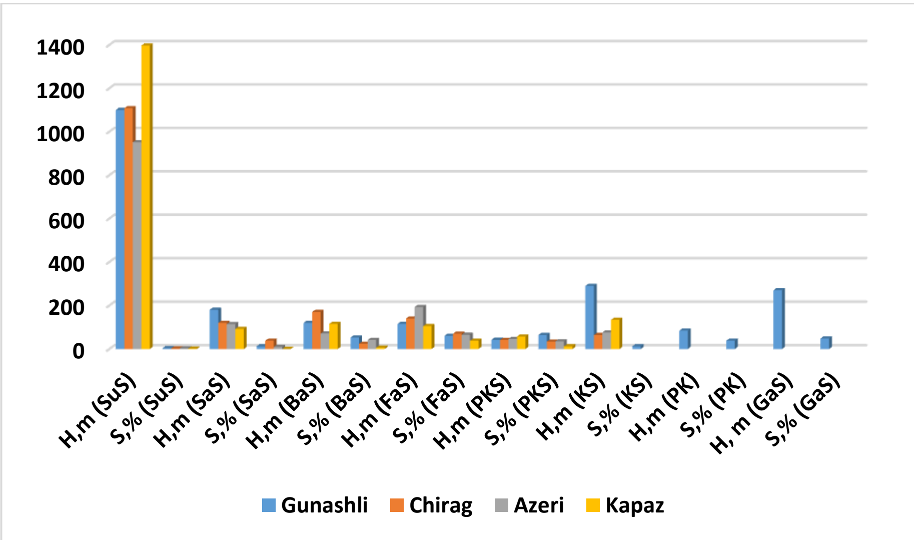

Figure 6: *The thickness and sand content of suites of the PS sediments along the southwest limbs of the structures*

The thickness of the IV horizon of SaS varies as following: in the Gunashli area- 155-173 m, in the Chirag area -between 90-122 m, in the Azeri area- up to 114 m, while up to 92 m in the Kepaz area. The sand content of the this horizon of 6-9% in the Gunashli, 14-39% in the Chirag, and up to 9% in the Azeri areas is found.

The thickness of the V horizon of BaS varies between 69-79 m in the Gunashli, 131-140 m in the Chirag, up to 148 m in the Azeri, and up to 83 m in the Kepaz areas. Amount of the sand along horizon ranges 14% in the Gunashli area. 13-20% in the Chirag, 12% in the Azeri, and up to 12% in the Kapaz areas is identified.

The thickness of the horizon VI of BaS 104-145 m, 100-175 m, up to 71 m and 115 m in the Gunashli, Chirag, Azeri, Kapaz areas is observed. The sand content 10-29% -in the Gunashli, 24% -in the Chirag, 41% -in the Azeri, and up to 6% -in the Kapaz area is noted.

The thickness of the BaS (VII horizon) varies as following: in the Guneshli area- 126-136 m, in the Chirag area- 110-118 m, in the Azeri field- up to 107 m, while up to 86 m in the Kapaz. The sand content of the horizon 27% in the Guneshli, 1-32% in the Chirag, 13% in the Azeri, and 17% in the Kapaz areas is considered.

The thickness of the horizon VIII section 114-131 m in the Gunashli, 145-166 m in the Chirag, up to 140 m in the Azeri, and up to 98 m in the Kapaz fields is found. The sandiness its up to 12% in the Chirag, 74% in the Azeri, and 8% in the Kapaz areas is observed.

The thickness of the BaS horizon IX varies between 125-147 m in the Gunashli field, between 86-133 m in the Chirag field, up to 150 m in the Azeri field, and up to 100 m in the Kapaz field. The sand content of the BaS IX horizon is between 11-23% in the Gunashli area, 24% in the Chirag area, 28% in the Azeri area, and 18% in the Kapaz area.

The thickness of the X horizon is 64-111 m thick in the Gunashli area. İn the Chirag area it is 105-110 m, up to 110 m in the Azeri, and up to 84 m in the Kapaz area. The sand content its changes 25-40% -in the Gunashli, 28-31% -in the Chirag, 39% in the Azeri, and up to 20% in the Kapaz areas.

FaS thickness fluctate in 107-119 m in the Gunashli field section, however, 110-149 m in the Chirag, up to 193 m in the Azeri, and up to 105 m in the Kapaz areas sections. Amount of sand 48-55%, 65-72%, 65%, and up to 39% along the section of the fields.

The thickness of the PKS suite rocks varies up to 44 m, 41m, 46m and up to 57m in the Gunashli, Chirag, Azeri, and in the Kapaz fields, respectively. The sand content of the suite reches up to 30% in the Guneshli, 34% in the Chirag, 35% in the Azeri, and 12% in the Kapaz areas.

The thickness of KS varies up to 371 m in the Gunashli area, up to 64 m (uncovered) in the Chirag area, up to 76 m (uncovered) in the Azeri area, up to 134 m (uncovered) in the Kapaz area. The sand content up to 8% in the Gunashli area is found.

The thickness of PK suite is 78 m, and the sand content up to 49% in the Gunashli area is abserved.

The thickness of GaS is 315 m in the Gunashli area, and the sand content varies up to 23%.

Based on the thickness correlation scheme along the Pirallahi-Janub-2 anticline line the thickness of individual layers increases from northwest to southeast (see, fig.2).

The thickness of the PS suites of the Chilov-Neft Dashlari anticlinal zone is greater in the southwestern limb than in the northeastern one. This shows that there is no influence of tectonic movements in the accumulation of those sediments in the southwestern limb.

In the Gunashli-Kapaz anticlinal zone, the thickness of the sediments increases in the direction of the Azeri field, and relatively decreases towards the Kapaz area. A sharp increase in thickness (1430 m) in the Kapaz area is observed in the VI horizon (137 m) of the Surakhani and the Balakhani suites. Accordingly, it can be noted that the rate of descent of the basin floor increased from the Azeri area to Kapaz during the deposition of Surakhani suite sediments. During the accumulation of the remaining suites of the PS, the regime of tectonic movements in the basin was the same.

The characteristics of the thickness changes of the PS suites show that the tectonic movements and the relief of the basin bottom play a key role in the thickness distribution.

The obtained results indicate that along the Pirallahi-Janub-2 anticline, the sand content increases from the Pirallahi area to the NE, from the Khali area to the NE in the Khali-Kapaz anticline line, reaches its maximum in the Gunashli-Chirag-Azeri areas, and decreases relatively towards the Kapaz area.

In many cases, the occurrence and distribution of hydrocarbons in sediments of the same stratigraphic age do not follow a clearly explained pattern. Therefore, in order to clarify the presence of any regularity sought in different structures, the obtained complex geological-geophysical data must first be analyzed within a specific structure. The increase in hypsometric depth in the western part of the South Caspian basin and the high gas saturation of the PS prove that the productive areas in this region have spread over a large area.

Except of the A.Aslanov and the Janub anticlinal structures, the arch parts of all deposits are of brachyanticlinal type, subjected to disjunctive dislocation to varying degrees.

Depending on the depth, while the Balakhani and Fasila suites in the Neft Dashlari (260-1300 m depth range) and Gunashli structures (2460-2710 m depth range) are oil fields, the continuation of these suites to the Janub-1,2 fields (2575-4690 m depth range)) are gas condensate.

The KS is oil-bearing in all known fields of the archipelago (depth intervals 480-1800 m), except of Janub-1 gas condensate field. The PK suite is oil-bearing in the Pirallahi, Gurgan-deniz, Chilov Island, A.Aslanov, Palchig Pilpilesi, Neft Dashlari fields (depth interval 650-2600 m), while is gas-condensate-bearing in the Janub-1, Gunashli fields (at a depth of 3260-5200 m) [7]. Variations are also observed due to stratigraphic distribution in individual deposits. So, if all the intermediate layers, from the Sabunchi suite to the PK suite including, layer in the structures of Neft Dashlari, Chilov Island are characterized by oil deposits, then oil and gas deposits are known in the Gala suite (GaS), which is involved in the geological structure of these areas.

The Western Absheron field, including Chilov Island (Western Absheron, Absheron bank, Darwin bank, Pirallahi Island, Gurgan-deniz, and Chilov Island), oil deposits are assossated with PKS, KS and PK suite sediments [14].

The oil-gas-bearing deposits are found in the GaS sediments which lie deeper than these formations in the Garbi Apsheron, Chilov Island and Neft Dashlari structures of the area. It is a special case that the "Fasila" suite in the Kapaz structure, which is located in the continuation of this zone, is oil and gas-bearing. So, in known fields (Neft Dashlari, Gunashli, Chirag, Azeri) "Fasila" suite is oil saturated.

During the test of well 1 drilled in the north-east limb of the Kapaz field (3527-3491 m), 286 t of oil and 20 thousand m^3 of gas per day were obtained from the FaS by the open flow method. 375 t of oil and 35 m^3 of gas per day were obtained from the 3725-3682 m interval of well 3 in the southwest limb. During the test of well 5 dug in the southwest limb, a gas flow with a daily output of 100,000 m^3 was obtained from a depth of 3684-3640 m. If we take into acount that the KS (Gunashli), PK (Gunashli, Chirag), PKC (Gunashli, Chirag, Azeri), Balakhani (Gunashli X horizon) suites are gas-condensate-oil-bearing in the neighboring fields, and the similarity of the geological structure and geological development history, hydrogeological conditions, etc. of the Kapaz field with these fields , it can be assumed here the high prospectivity of the suites of the same name of the PS (Fig.7).

If you follow the productive horizon of the same name along a certain area, it is observed that there are different products in them. For example, the PKS suite is oil-bearing in the Chilov Island, the Janub, the Palchig Pilpilesi, and the Neft Dashlari fields, while it is gas-condensate-bearing in the Gunashli, Chirag, Azeri fields. There can be two explanations for the observation of such a situation in this structure. First of all, it can be explained by the free diffusion of gas dissolved in oil through geotectonic dislocations that occurred in the long geological period as a result of low formation pressure and temperature in shallow deposits. On the other hand, oil-gas, oil, gas condensate deposits form a strip of independent deposits located in different zones in the same region.

If the latest actual data is taken as the basis, in the direction of the Gum-deniz, Janub-1, Janub-2, Gunashli and Bahar-Azeri-Kapaz fields, there are rich underground (buried) intermediate structures, where productivity of Fasila, PKS, KS, PK and GaS are possible. In addition, based on new seismological and geophysical studies of wells, it is shown that the continuation of the oil-gas-bearing deposit of the Fasila suite in the Kapaz structure corresponds to the top of the VII oil-gas-bearing horizon of the Red series in the Turkmenistan sector [1, 2].

In this regard, the study of the regularity of the location and distribution of hydrocarbon deposits in the Absheron-Balkan archipelago plays a key role.

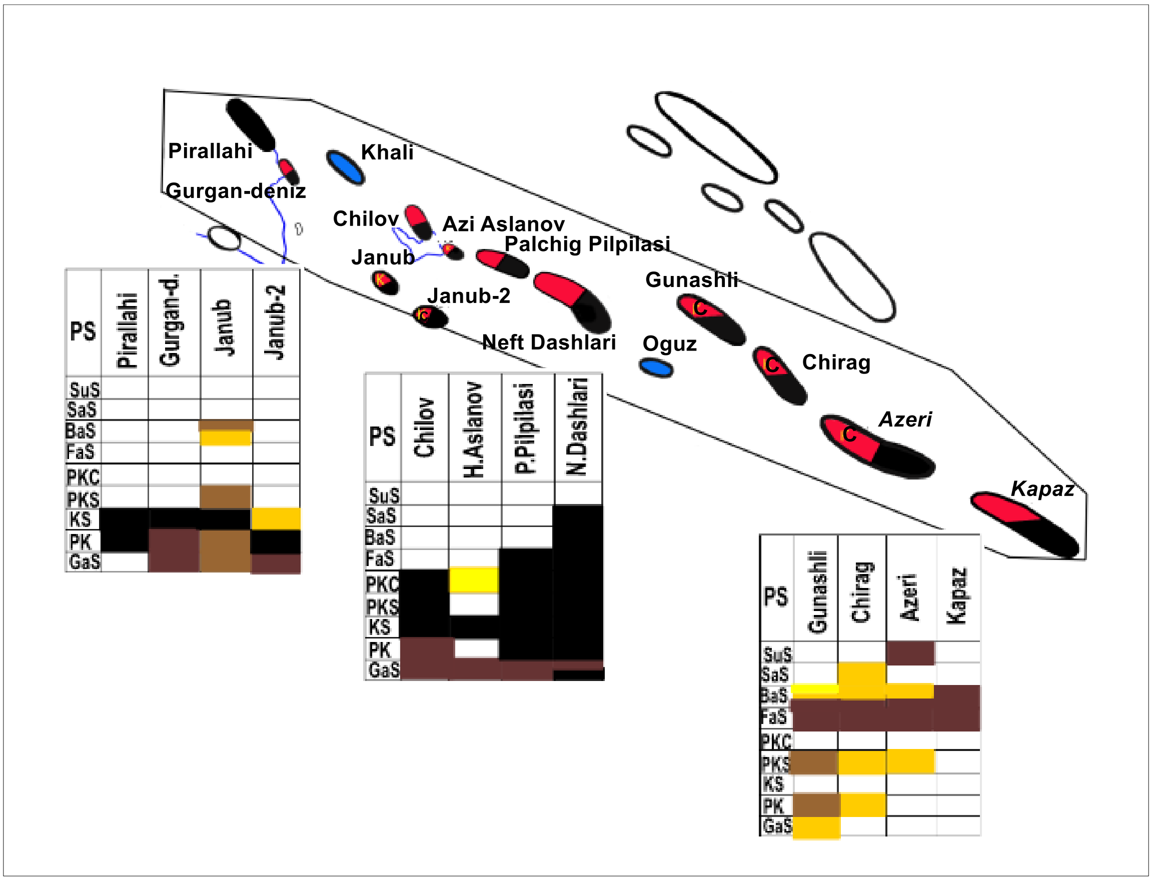

Figure 7: *Oil and gas deposits distrubution within fields*

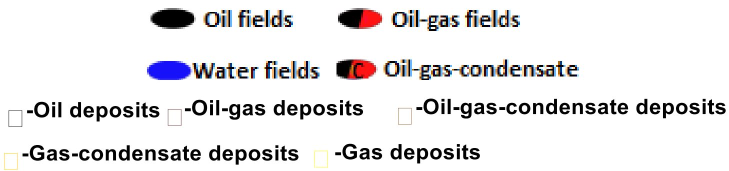
Legend:



The level of complexity of the folds with faults mentioned here is different and play a fundamental role in the distribution of oil and gas fields [4]. It is known that, in one case, longitudinal faults play a role as oil and gas migration paths, both in their formation and in the destruction of deposits in Pliocene, Miocene-Paleogene, Upper Cretaceous and older sediments, and in the other case, as a screen in separate tectonic blocks and near-faulted zones prevents the displacement of oil and gas and form conditions to the accumulation of hydrocarbons. In the process of development of regional faults, transverse faults formed at separate stages create conditions for the formation of tectonic screened microblocks and its prevent the destruction of deposits in these microblocks [6]. Longitudinal faults play a key role in the distribution of hydrocarbon accumulations in the fields of Absheron oil and gas-bearing region. Transverse faults reshape the oil fields in Pliocene sediments by giving a stepped shape to the folds. It should be noted that here longitudinal faults are developed in the lower stage of the PS, and transverse faults often developed in the upper stage. The Janub, Janub-2 folds are complicated by normal faults. The formation of deposits through vertical migration along faults caused by tensile stress leads to the formation of a zone of deep oil and gas accumulation in the basin. This zone can be distinguished as the main oil and gas zone of the basin, which is located above the oil and gas formation sourses. Within it, the deposits are grouped along the main tensile zones and the faults branching from them. Regarding the formation of oil and gas deposits, it should be noted that this process is usually stepwise, that is, they are formed as a result of the alternating activity of vertical and lateral migrations. Therefore, in the chain-arranged ascents within the mentioned zone, in the southeast-northwest direction, so, in the direction of ascent of the layers, the differential entrapment of oil and gas is justified [5]. That is, along the Pirallahi-Janub-2 anticlinal zone, gas-condensate deposits are replaced by oil-gas and oil deposits in the southeast-northwest direction. The suites of the lower stage of the PS in the Gunashli-Kapaz anticlinal zone are mainly characterized by gas-condensate deposits, and the suites of the upper stage are mainly characterized by the presence of oil-gas accumulations.

IV. Conclusion

1. According to the results of the analyzes conducted in the Pirallahi-Janub-2, Khali-Neft Dashlari, Gunashli-Kapaz anticlinal zones, the thickness and sand content of the suites of the lower and upper stages of the PS are increas from northwest to southeast along of the northeast and southwest limbs of the structures.
2. The characteristics of the thickness changes in the PS suites show that the tectonic movements and the relief of the basin bottom play a key role in the distribution of thicknesses.
3. The GaS, PK, PKS, Balakhani suites are gas-condensate-oil-bearing in the adjacent fields. Taking into account this factor it is possible to note the high prospects of the suites of the same name of PS in the Kapaz field, due to the similarity of geological structure with these fields.
4. Faults that complicate structures play a key role in the formation of hydrocarbon deposits.

Abstract

This paper delves into the utilization of tax policy as a strategic tool for promoting sustainable development, comparing international practices with the Russian experience. Tax policy, when aligned with sustainability objectives, can drive economic growth, foster social equity, and protect the environment. The paper reviews various tax instruments such as carbon pricing, eco-taxes, incentives for renewable energy investments, and tax benefits for sustainable business practices, focusing on how they have been implemented globally and in Russia. Special attention is given to policies that address environmental externalities and encourage the transition to a low-carbon economy. In the case of Russia, the paper assesses the effectiveness of recent tax reforms aimed at fostering sustainable development, including energy efficiency incentives and efforts to diversify government revenues beyond fossil fuels. By examining successes, limitations, and lessons learned from both international and Russian contexts, the paper provides actionable recommendations to strengthen the role of tax policy in advancing sustainable development.

Keywords: tax policy, sustainable development, carbon pricing, environmental levies, renewable energy incentives, green fiscal reform, climate change mitigation, sustainable economic growth, eco-taxes, low-carbon economy

I. Introduction

The modern world faces a number of global challenges related to the need to ensure sustainable development (Fig.1). The concept of sustainable development includes three interrelated aspects: economic growth, social well-being and environmental safety. In the context of these tasks, tax policy becomes an important tool for achieving sustainable development goals. Properly designed tax mechanisms can not only promote economic growth, but also stimulate responsible use of natural resources and reduce negative impacts on the environment.

Many countries are already actively using tax instruments to promote environmental initiatives and support the transition to a low-carbon economy. Carbon taxes, environmental charges and tax incentives for "green" technologies are just a few examples of successful measures applied at the international level. Russia is also taking steps in this direction, introducing tax reforms aimed at reducing dependence on hydrocarbons and supporting innovative environmentally friendly technologies.

Introducing elements of sustainable development into tax policy is a complex process that requires taking into account the specifics of national economies and adapting to international trends. This article analyses international experience in using tax policy to stimulate sustainable development and examines how Russia is adapting these approaches to address its own environmental and economic challenges.

Figure 1: *Sustainable Development Solutions Network*

The International Spillover Index is a metric designed to evaluate how a country's actions affect the ability of other nations to achieve the Sustainable Development Goals (SDGs). This index quantifies the international ripple effects resulting from a country's policies and practices, providing valuable insights into their broader implications.

The index considers three main dimensions of these spillover effects:

1. Environmental and Social Impacts: This dimension examines the environmental and social repercussions associated with trade practices, such as pollution resulting from production activities intended for export. It highlights how a country’s production methods can affect ecological sustainability and social well-being in other regions.

2. Economic and Financial Spillovers: This aspect assesses how economic policies and financial events in one country can lead to spillover effects that impact neighboring or distant nations. For instance, financial crises can spread across borders, leading to economic instability and adverse effects on development efforts elsewhere.

3. Security Spillovers: This dimension analyzes how instability or conflict in one country can affect the security and stability of other nations. It underscores the interconnectedness of global security, where challenges in one region can lead to increased risks and challenges in another.

By measuring these dimensions, the International Spillover Index provides a comprehensive overview of the ways in which countries' actions can support or hinder the achievement of global sustainable development objectives.

II. Methods

A comprehensive methodological approach, including qualitative and quantitative research methods, was used to analyze the role of tax policy in stimulating sustainable development.

1. Comparative analysis: The main method used was a comparative analysis of tax practices in various countries aimed at supporting sustainable development. The study covers the experience of both developed and developing countries, including Russia, the European Union, the United States, China and a number of other countries. The comparison includes a study of carbon taxes, environmental charges and incentives for the introduction of renewable energy sources.

2. Analysis of the regulatory framework: A study of existing laws and regulations in Russia and abroad related to environmental and tax policy was conducted. This allowed us to identify the key tax instruments used to stimulate environmentally friendly technologies, energy efficiency and reduce the carbon footprint.

3. Econometric analysis: Econometric modeling methods were used to quantitatively assess the impact of tax instruments on sustainable development. The study examined GDP, carbon emissions, energy efficiency and green investment indicators in countries with different tax regimes. This made it possible to identify correlations between tax measures and improvements in environmental and economic indicators.

4. Case studies: Specific examples of successful application of tax policy to promote sustainable development were analyzed. Cases from Russia and other countries were considered to identify key success factors and obstacles in the implementation of "green" tax reforms.

5. Expert interviews: To obtain practical data on the application of tax policy in the context of sustainable development, interviews were conducted with Russian and international experts in the field of ecology, tax law and economic development. This helped to complement the theoretical analysis with real examples and forecasts for the further development of tax policy.

Thus, the use of several research methods provides a comprehensive analysis of the role of tax policy in achieving sustainable development goals, taking into account both international and Russian experience.

III. Results

Environmental sustainability is another key area where taxation can have a significant impact. Environmental taxes, such as carbon taxes, aim to incorporate external environmental costs associated with environmental degradation into the price of goods and services. By imposing taxes on environmentally damaging activities, such as fossil fuel use or industrial pollution, governments can discourage environmentally harmful practices and encourage the use of cleaner technologies. For example, carbon taxes create an economic incentive for companies and individuals to reduce their carbon emissions, thereby helping to mitigate climate change. Revenues from environmental taxes can be used to support sustainable projects, such as renewable energy, energy efficiency, and environmental programs, thereby amplifying the impact of environmental initiatives. In addition, tax policy can play an important role in shaping corporate behavior and encouraging sustainable business practices. Through tax incentives and subsidies, governments can encourage companies to invest in sustainable technologies, adopt clean production methods, and stimulate innovation for sustainable development. For example, tax incentives for research and development in renewable energy can encourage innovation in this sector by making clean energy more affordable. Similarly, tax incentives for companies that meet environmental or social standards can motivate greater corporate responsibility and sustainability.

International tax cooperation also plays a critical role in promoting sustainable development, particularly in combating tax evasion. The globalization of the economy has made it easier for multinational corporations and wealthy individuals to shift profits and assets to countries with low tax rates, eroding the tax bases of countries, especially developing countries. International initiatives such as the OECD-led BEPS (Base Erosion and Profit Shifting) project aim to address these problems by increasing transparency and ensuring that taxes are paid in the countries where the real economic activity takes place. Combating tax evasion helps protect the revenue needed to achieve sustainable development goals.

IV. Discussion

The underlying cause of many development issues in the Far East, and in Russia more broadly, is the lag in research and development (R&D) progress. This problem is well-known, and a widely adopted solution in numerous countries is the introduction of specific tax incentives to stimulate growth. In this context, a key strategy would be to enhance tax benefits for residents of special economic zones (SEZs), which act as small but dynamic "growth hubs" in the Far East. These hubs can foster the creation of new technologies that, once disseminated throughout the region, could significantly improve overall development metrics.

Studies by Zhang et al. [8], Gasmi et al. [9], and Yuan et al. indicate that well-targeted tax incentives lead to a more efficient use of existing infrastructure, human resources, and other critical assets.

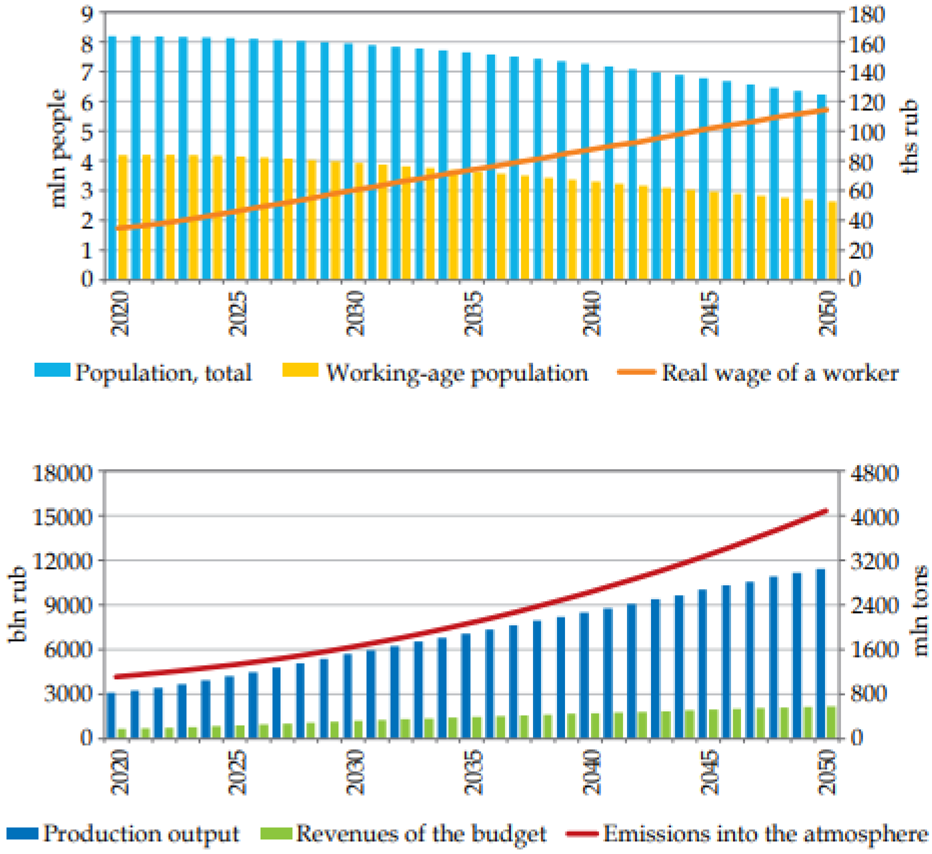

Figure 2: *Inertial scenario. Indicators characterizing the dynamics of the region's economic-technological and socio-ecological subsystems*

Currently, the SEZs operating in the region offer a variety of tax benefits and incentives aimed at attracting businesses. These include reduced corporate income tax rates, lower social insurance contributions, and reduced land tax rates. Such measures help improve business profitability, often measured by return on equity (ROE), which is undoubtedly a crucial factor for enterprises. However, profitability alone is not sufficient, especially given the region's prolonged economic challenges and the relatively weak innovation drive within the private sector. To address these issues, it would be prudent to introduce tax incentives that are tied to reciprocal commitments from businesses, particularly in the areas of innovation and capital investment.

This approach would involve structuring tax incentives around contractual obligations. A prime example could be the implementation of an Investment Tax Credit (ITC), allowing businesses to offset their tax liabilities. A similar mechanism is successfully employed in Italy, where companies are offered a generous 12% tax credit on qualified R&D expenditures, which can be used to reduce any type of tax obligations. Such a policy could serve as a model for fostering innovation and investment in the Far East's SEZs.

The effectiveness of taxation in promoting sustainable development is closely tied to the efficiency and fairness of tax administration. A fair and transparent tax system that minimizes evasion and ensures compliance is crucial for building public trust and making tax revenues available for development purposes. Efficient tax administration reduces the costs of tax collection and increases the revenues available for public investment. Fairness in tax administration ensures an equitable distribution of the tax burden, preventing undue hardship for low-income individuals and avoiding the concentration of wealth.

In conclusion, taxation serves as a fundamental tool for achieving sustainable development. It provides the necessary revenues for public investments in critical sectors, facilitates income redistribution to reduce inequality, and encourages environmentally sustainable practices. An effective tax policy can stimulate economic growth, promote social integration, and protect the environment by aligning national development strategies with global sustainable development goals. The role of taxation extends beyond revenue generation; it encompasses the facilitation of equitable economic growth, environmental protection, and social welfare. Therefore, the development and implementation of tax policies must continuously adapt to the evolving challenges and opportunities of sustainable development. Through progressive, efficient, and fair tax systems, governments can harness the power of taxation to build a more sustainable and equitable future for all.

Tax incentives encompass various aspects related to green technologies, and their analysis can be instrumental in defining the trajectory for transforming tax instruments that stimulate investment in these technologies. Many countries have established tax incentives to encourage investors. In the United States, such incentives are provided through tax exemptions and accelerated depreciation for corporate profits. Tax benefits are also available for specific business activities, including green investments, based on the Opportunity Zones legislation, which has been in effect since 2017. The aim of reducing the tax burden is to motivate ESG investing across various sectors, emphasizing the importance of capital allocation that considers environmental protection, social development, and corporate governance.

To control environmental pollution and ensure the safe handling of solid waste and the recycling of valuable materials, the Pollution Control Tax-Exempt Bond Financing Program has been established. This program allows borrowers to lower the cost of financing clean technologies through reduced interest rates compared to conventional loans. Green bonds for environmental projects that meet climate investment standards are actively issued by the California Pollution Control Financing Authority (CPCFA). Eligible projects for tax-exempt bond financing include the creation and reconstruction of wastewater treatment facilities, waste-to-energy conversions, waste disposal, and landfill reclamation. The effectiveness of tax incentives in the U.S. is evidenced by the increase in reported and supported projects. For instance, the list of projects receiving financial assistance and tax benefits includes initiatives for purchasing clean vehicles for waste management companies and recycling used oil, as well as construction debris disposal projects. Some of these incentivized projects can be implemented by small businesses and supported at the municipal level, thus stimulating local economic development. Overall, U.S. tax incentives have resulted in investments in green projects averaging up to $15 billion per year, positioning the country as a leader in green technology.

In Malaysia, a comprehensive set of green tax incentives is available for industrial enterprises and investors. Funding for clean technologies is facilitated through the Green Technology Financing Scheme (GTFS 3.0), which was launched as part of the Sustainable and Responsible

Investment (SRI) support program aimed at promoting the adoption of green technologies. This scheme enables the incorporation of green technology elements into investment projects while reducing the tax burden. It includes tax incentives for electric vehicles, profit tax exemptions, and the Green Income Tax Exemption (GITE), as well as the Green Investment Tax Allowance (GITA).

Conversely, the current taxation framework in Russia does not include specific provisions for modifying elements related to green technology, such as tax bases, exemptions, or rates. The concept of green technologies is not explicitly defined in Russian regulatory documents. Traditionally, green technologies are associated with those that do not harm the environment or, when utilized, cause minimal ecological damage.

Abstract

The article discusses the problems of developing and justifying a strategy for the geological study and preparation of oil reserves from marginal oil and gas fields in the Caspian sector of Azerbaijan. The scientific works of domestic and foreign scientists studying issues related to the use of subsoil containing volumes of recoverable reserves, located in difficult geological and field conditions and located in remote, inaccessible areas with poorly developed infrastructure, are presented in detail. In addition, unclaimed oil reserves have been scientifically analyzed to determine the industrial significance of the objects and to determine the conditions for the profitable development of marginal offshore fields.

Keywords: fields, marginal, development, strategy, model, oil reserves, category

I. Introduction

The energy strategy of Azerbaijan for the period until 2035 determines that the Caspian sector of the republic will remain the main subsoil use areas that ensure an increase in oil and gas reserves. Solving the assigned tasks will require SOCAR (Azerbaijan Republican State Oil Company) to develop and justify a strategy for geological study and preparation of subsoil reserves. At the same time, the modern oil industry of Azerbaijan is characterized by a decrease in the quality of the natural characteristics of explored offshore fields. In these conditions, SOCAR faces the question of the need to prepare low-profit oil reserves that fall into the category of so-called marginal fields [1].

The calculation results show that the share of proven reserves in the offshore structure of the oil and gas sector is extremely high and comparable to the oil resources currently under development. Maintaining advantageous positions and dynamic development of the extractive sector based on marginal oil fields (MOR) will obviously require oil companies to introduce fundamentally new technological solutions and financial schemes for their development. In addition, at the level of government management of the industry, it is necessary to provide for the creation of a favorable taxation regime and measures to increase the investment attractiveness of MMN projects.

Solving these problems requires the formation of strategic priorities for the involvement in the development of a new cluster of low-profit offshore oil fields and the substantiation of an organizational and economic mechanism (OEM), which provides for a system for stimulating the processes of development of the international oil production complex based on interaction with SOCAR with the participation of scientific, technical and educational centers.

Providing the needs of the republican economy with hydrocarbon raw materials in the long term and maintaining the country's position in the global hydrocarbon raw materials market is state policy.

As world experience shows, consumption of fuel and energy raw materials in individual countries depends on the level of economic development of the countries [2]. As economic potential grows, scientific and technological progress increases, and the needs of the population increase, the volumes of mineral resources used expand. According to foreign experts, over the past 40-50 years, 70-80% of the oil, about 40% of the coal and iron ores mined by mankind throughout history have been sold. According to many scientists and experts, by 2050 the demand for energy and its production will more than double.

The above necessitates the consolidation of all energy sources to meet the expected growth in its demand; competition between various energy sources (natural gas, oil, coal, hydropower, nuclear energy, and in the future – solar, wind, geothermal, etc.) is especially inevitable.

It should be noted that the existing mechanisms for regulating the global energy market do not work in the global energy sector. It is increasingly obvious that competition between consumers is becoming more intense due to the emergence of such powerful players as China and India in the market. While the main consumers of oil are highly developed countries, the bulk of the world's hydrocarbon reserves are concentrated in a relatively small group of developing countries and countries with economies in transition. Large consumers such as the United States and the European Union are concentrating economic and political resources to expand into markets, which leads to increased competition.

II. Methods

In the specialized scientific literature of both domestic and foreign scientists studying subsoil issues, the terms "marginal deposit" or "marginal object" lack a unified interpretation. It is often used to classify groups of fields containing small volumes of recoverable reserves, located in difficult geological and field conditions and located in remote, inaccessible areas with poorly developed infrastructure. In contrast to our approach, foreign countries extensively study and develop marginal oil fields. This is due to the fact that in countries with a developed mining industry, but with limited hydrocarbon reserves, some types of marginal oil deposits have been developed quite successfully for a long time. This includes the positive experience of Canadian companies that have ensured the cost-effective development of high-viscosity oils and oil sands [3,4,5]. A classic example of the development of marginal deposits is the emergence of a new sub-industry of the US oil industry, focused on the integrated development of so-called shale oil deposits [6,7]. The term "marginal oil reserves" is spelled out in regulatory documents and laws, which indicates that the issues of studying and developing these fields have been addressed at the state level. For example, in the countries of North America (USA, Canada), a special preferential tax regime has been developed for companies developing such deposits [6].

From our perspective, the category of 'marginal development object' primarily pertains to the economic aspect and combines objects that have a marginal degree of profitable development. For marginal oil reserves, the most important criteria for their development by oil producing enterprises are net present value (NPV), internal rate of return (IRR), and increase in reserves for each manat of invested funds. The main task of this stage is to determine the best available technologies for studying and developing a marginal object, as well as the investments required for its implementation.

At the same time, projects for the development of marginal reserves of offshore oil fields, such as Oil Rocks, Divanny, Khara-Zira, Peschanny and others, which are at the stage of geological study or industrial development, are presented with a high degree of detail. In order to develop deposits for investing in such projects, the company has a complete understanding of the technological scheme of their development, which can be obtained during their implementation [8].

The organizational model for the study and development of marginal oil fields can be implemented by creating a sustainable oil industry complex that can ensure cost-effective exploration, production, and transportation of raw materials by integrating innovative technologies into production.

It should be noted that the development and implementation of optimal projects will allow obtaining the following economic effects:

- increase in oil production volumes due to the exploitation of previously unclaimed resources;
- attracting additional volumes of domestic and foreign investments;
- stimulating the introduction of innovative technologies;
- reducing the payback period of investments;
- increase in oil recovery factor.

Based on the study and generalization of the works of Academician A.Kh. Mirzajanzadeh, B.A. Sudeimanova, A. A. Gerta, V. I. Nazarova, Yu. P. Ampilova, A. G. Zdotnikova, R. S. Khirsanova and others in the field of geological and economic assessment of oil and gas reserves and resources, we have introduced three criteria (marginally profitable, conditionally profitable, unprofitable) marginal reserves according to the economic efficiency of their development.

We believe that the development and commissioning of marginal offshore oil fields can contribute to the rational use of subsoil in Azerbaijan. At the same time, the creation of a flexible system by SOCAR will have a positive effect on oil production. However, there is little to no action in this direction from both the state and SOCAR's subsoil management.

Based on well-known domestic and foreign definitions of MOR, these include the following categories of promising hydrocarbon objects: unclaimed, unconventional and hard-to-recover. Unclaimed reserves may include hard-to-recover and unconventional reserves, and hard-to-recover reserves may include unclaimed and unconventional reserves (Fig. 1).

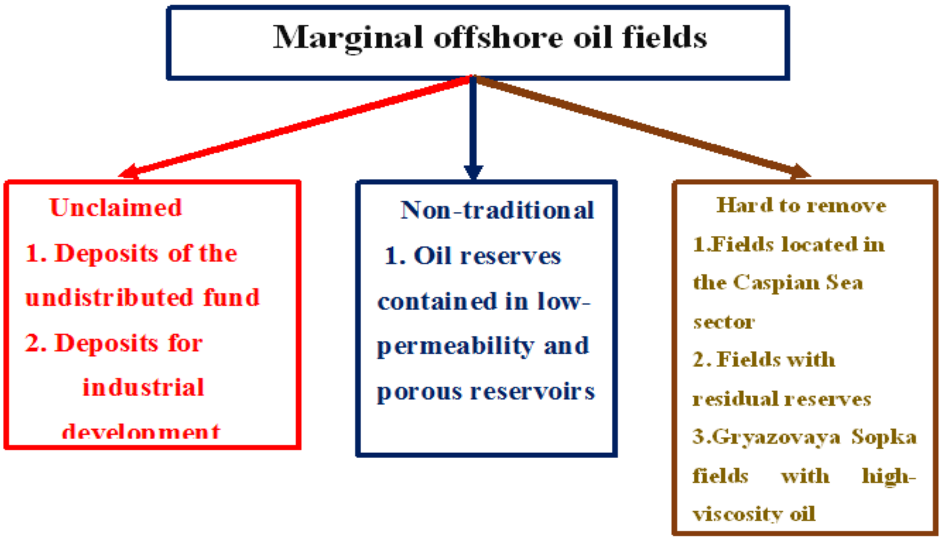

Figure 1: *Classification of marginal offshore oil fields of SOCAR*

III. Results

As can be seen from the figure, unclaimed oil reserves include those resources whose development from a technical and economic point of view is not feasible given the current situation in the global oil market. These reserves belong to the distributed and undistributed subsoil fund and are located in undeveloped layers. In addition, it is proposed to classify unappraised deposits within local objects as unclaimed. Unconventional oil reserves include those located in low-permeability and low-pore reservoirs. When developing unclaimed oil reserves, the following factors determine the industrial significance of the objects:

- complexity of the geological structure;
- lack of modern equipment and production technologies;
- remoteness from industrial infrastructure deposits;
- low prices for crude oil in the domestic markets.

Hard-to-recover oil reserves are characterized by unfavorable geological conditions and are highly viscous.

The main difference between traditional and unconventional reserves and resources from an economic point of view is that the development of the latter requires the use of significantly more investment-intensive technologies.

When studying the category of marginal development objects, the fundamental question is to determine their role in ensuring the sustainability of the development of the country's oil and gas complex. The basis for such development is the processes of reproduction of the mineral resource base of the country's oil and gas resources as the reserves of the developed fields are depleted [9,10].

We have defined the role of marginal deposits as follows: when highly profitable reserves are reduced, the process of industrial development and development involves deposits and extraction of reserves, which are characterized by a lower degree of profitability. At the final stage of development of offshore fields, low-profit fields are introduced into the process of industrial development.

Assessing the industrial significance of marginal deposits requires evaluating various factors such as geological, mining, and economic conditions. These factors, which vary among enterprises and change over time, collectively determine the effectiveness of marginal oil facilities.

The problem of assessing the limiting parameters of marginal objects is associated with the lack of sufficient methodological and practical experience in their development. In addition, promising objects containing marginal oil reserves have been little studied and do not have approved project documents by SOCAR. But for oil producing enterprises, it is important to have projects at the initial stage of geological exploration or industrial development of objects.

Currently, one of the few methods for conducting economic assessment is the construction of an economic-mathematical model for assessing acceptable parameters for the development of marginal objects. At the same time, in order to assess the economic efficiency of developing marginal oil reserves, it is necessary to justify prices for crude oil on the domestic market, and calculate the volume of capital and operating costs.

A change in the direction of decreasing or increasing the volume of recoverable marginal oil reserves, subject to changes in their depth and oil production rate of wells, is calculated based on an assessment of the capital and operating costs required for field development. With the definition, it is possible to calculate the minimum technological and economic initial data acceptable for development. The amount of capital costs associated with the construction of production and injection wells, and, accordingly, the costs of their operation, depends on the depth of the formations.

With an increase in the price of oil on the world market, revenues from the implementation of a project for the development of marginal oil reserves increase. At the same time, the volume of tax revenues to the State Budget increases. If world oil prices decline, the opposite situation occurs.

Conclusion

1. Sustainable development of the oil production complex of marginal offshore oil fields directly depends on SOCAR's technological capabilities to ensure cost-effective development and development of low-profit deposits.

2. In all the leading oil companies of foreign countries, there are many solutions that differ from each other in the methods and technologies used for the development of marginal oil fields. However, SOCAR has few methods for increasing oil recovery are used mainly in depleted oil fields for the purpose of conducting pilot tests.

3. Currently, the main strategic directions of development of SOCAR-BP cooperation in the field of studying and developing marginal oil reserves of the Caspian sector of Azerbaijan are the development of joint projects in the field of creating highly effective technological solutions aimed at increasing oil recovery, since their implementation in the oil and gas producing enterprises of the republic will lead to to reduce costs and will allow such facilities to be brought to a profitable level.

Abstract

This paper delves into the significant role that environmentally oriented start-ups play in transforming traditional sectors of the economy. As the world grapples with pressing environmental challenges such as climate change, resource depletion, and biodiversity loss, these innovative enterprises are emerging as vital agents of change. The study investigates how these start-ups disrupt conventional business models by implementing sustainable practices, enhancing resource efficiency, and promoting the principles of the circular economy. By harnessing cutting-edge technologies and innovative approaches, environmentally focused start-ups contribute to a range of economic activities that prioritize sustainability. They challenge traditional industry norms by offering greener alternatives, optimizing supply chains, and minimizing waste. This paper also explores case studies that exemplify the successful integration of sustainable practices into sectors such as agriculture, manufacturing, and energy, showcasing how these start-ups not only address environmental issues but also create economic opportunities and stimulate job growth. Furthermore, the findings emphasize the importance of supportive policies, regulatory frameworks, and collaborative ecosystems in nurturing the growth of these start-ups. The paper advocates for the establishment of partnerships between governments, established businesses, and start-ups to create an environment conducive to innovation and sustainability. By fostering collaboration, these stakeholders can ensure that environmentally oriented start-ups are equipped to make a meaningful contribution to the transition towards a green economy.

Keywords: environmentally oriented startups, transformation of traditional sectors, sustainable development, circular economy, innovation, sustainable practices

I. Introduction

The transformation of traditional sectors through the emergence of environmentally oriented startups marks a significant shift in the global economic landscape (fig.1). With growing awareness of climate change, resource depletion, and environmental degradation, these startups are stepping in to challenge established norms and drive innovation toward sustainability. They often operate at the intersection of technology, sustainability, and business, offering novel solutions that traditional industries can adopt to reduce their ecological footprints.

Role in Traditional Sectors.

In sectors such as agriculture, manufacturing, and energy, environmentally oriented startups are innovating processes and products that minimize environmental harm. For instance, in agriculture, these startups are developing precision farming techniques that optimize resource use and reduce chemical inputs, promoting sustainable food production. In manufacturing, companies are adopting circular economy principles, where waste is minimized, and materials are reused or recycled, significantly lowering production costs and environmental impact.

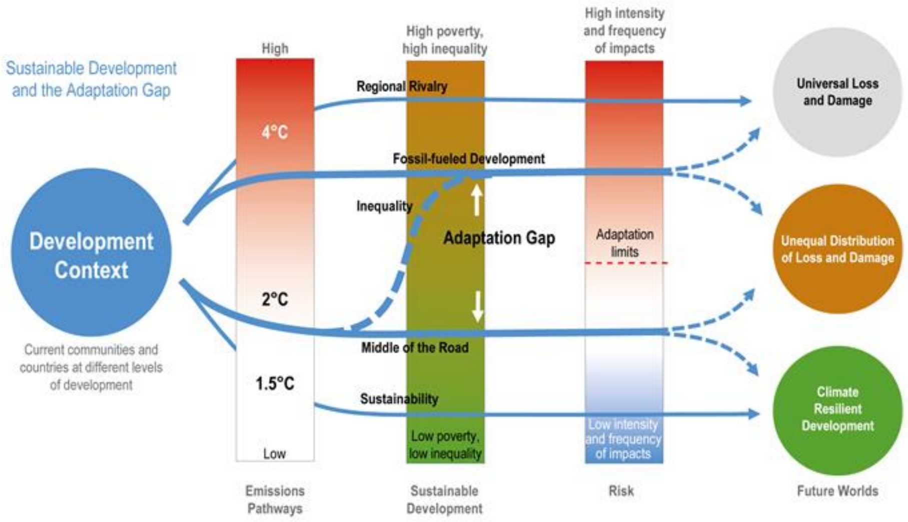

Figure 1: *Sustainable Development and the adaption gap*

In the energy sector, startups are spearheading the development of renewable energy technologies, such as solar, wind, and bioenergy. By providing affordable and accessible alternatives to fossil fuels, these startups not only reduce greenhouse gas emissions but also empower local communities and stimulate economic growth through job creation in green technologies.

Innovation and Collaboration.

Collaboration is another vital aspect of the role played by environmentally oriented startups. By partnering with traditional companies, these startups facilitate knowledge transfer and innovation diffusion. Established businesses often benefit from the agility and creativity of startups, allowing them to adopt sustainable practices more rapidly. This partnership can take many forms, including joint ventures, research collaborations, and supply chain integration, which ultimately foster a culture of sustainability within traditional sectors.

Moreover, startups often emphasize a stakeholder-centric approach, recognizing that environmental and social responsibilities go hand in hand. By engaging consumers and local communities in their initiatives, these businesses create a sense of ownership and accountability, driving broader societal change toward sustainability.

Policy and Regulatory Frameworks.

The role of government policy and regulatory frameworks cannot be understated in this transformation. Supportive policies, such as incentives for green innovation, subsidies for renewable energy, and stringent environmental regulations, create an enabling environment for environmentally oriented startups to thrive. Policymakers play a crucial role in fostering innovation ecosystems that facilitate startup growth by providing funding opportunities, incubators, and networks that connect startups with investors and industry leaders.

Furthermore, regulatory frameworks that encourage sustainable practices can significantly influence the behavior of traditional sectors. By mandating transparency in environmental reporting and promoting sustainability standards, governments can drive systemic change across industries, leading to a more sustainable economy.

Challenges and Future Directions.

Despite their potential, environmentally oriented startups face several challenges, including access to financing, market competition, and regulatory barriers. Many startups struggle to secure funding, particularly in the early stages, which can hinder their growth and scalability.

Additionally, competition from established companies with significant resources and market power can make it difficult for startups to penetrate traditional markets.

To overcome these challenges, it is essential to create a robust support system for environmentally oriented startups that includes financial backing, mentorship, and networking opportunities. Encouraging public-private partnerships can also help facilitate innovation and accelerate the adoption of sustainable practices in traditional sectors.

II. Methods

In exploring the role of environmentally oriented startups in transforming traditional sectors of the economy, a comprehensive methodological approach is essential. This section outlines three key methods that will be employed in the study:

1. **Case Study Analysis**
   - Description: This method involves an in-depth examination of specific environmentally oriented startups that have successfully transformed traditional sectors. Case studies will provide detailed insights into the strategies, innovations, and impacts of these startups on their respective industries.
   - Implementation: Selected startups from various sectors (e.g., agriculture, energy, manufacturing) will be analyzed. Data will be collected through interviews with founders, employees, and stakeholders, as well as through document analysis (e.g., business reports, press releases).
   - Expected Outcome: This method aims to identify best practices, challenges faced, and lessons learned that can inform other startups and traditional businesses seeking to embrace sustainability.
2. **Surveys and Questionnaires**
   - Description: Surveys will be used to gather quantitative data from a broader range of environmentally oriented startups and traditional businesses. This method will help assess perceptions, strategies, and the impact of startups on traditional sectors.
   - Implementation: A structured questionnaire will be developed, covering areas such as sustainability practices, collaborations with startups, and perceived barriers to adopting green innovations. The survey will be distributed to a sample of businesses in relevant sectors to collect data.
   - Expected Outcome: This method will provide statistical insights into trends, challenges, and opportunities related to the integration of environmentally oriented startups into traditional sectors.
3. Interviews with Key Stakeholders
   - Description: Semi-structured interviews will be conducted with key stakeholders, including entrepreneurs, industry experts, policymakers, and representatives from traditional sectors. This qualitative method will yield rich, nuanced perspectives on the role of startups in promoting sustainability.
   - Implementation: Interview questions will focus on experiences, opinions on the impact of startups, and recommendations for enhancing collaboration between startups and traditional businesses. The interviews will be recorded, transcribed, and analyzed for common themes and insights.
   - Expected Outcome: This method aims to capture diverse viewpoints and deepen understanding of the systemic changes driven by environmentally oriented startups in traditional sectors.

III. Results

A start-up is typically defined as a temporary organization or institution focused on finding a profitable, measurable, and scalable business model. The key differentiating factor is the high level of uncertainty faced by start-up ventures. As long as a product or service is entirely novel and untested, it remains uncertain how the market will respond. Generally, start-ups progress through two developmental phases: the experimental phase and the production phase. Currently, approximately 90 percent of start-ups worldwide fail to advance beyond the experimental stage. Global experience indicates that start-ups require support during this initial phase, often referred to as the "start-up ecosystem." This experimental phase typically lasts about five years, although some start-ups may experience longer or shorter durations, necessitating ongoing support from the ecosystem. Such ecosystems globally are characterized by clear legal and regulatory frameworks, diverse partnerships and collaborations, engagement from public and private stakeholders, and incentives that create a conducive environment for the establishment and growth of start-up ventures. The concept of an ecosystem in business, borrowed from ecology, was first defined by Start-ups play a crucial role in the development, growth, and long-term sustainability of economy, as they represent the future evolutionary path of the nation. Consequently, it is essential to encourage and support these ventures. Their significance is emphasized in Business and Investment Development Strategy 2021-2027, which outlines steps to promote innovation initiatives, allocate more funds for research and development, and create a more favorable environment for start-up growth.

IV. Discussion

The start-up revolution has been fueled by significant infusions of public and private capital, which provide the necessary resources for these ventures to scale quickly and transform their innovative ideas into reality. As start-ups expand, they garner attention from industry veterans, paving the way for collaborations that blend traditional expertise with fresh perspectives. Rather than competing for dominance, start-ups and established industries are increasingly discovering avenues for coexistence and collaboration. Start-ups bring new ideas and energy, while established players contribute industry knowledge and resources. This synergy fosters a harmonious ecosystem in which innovation can flourish, all while honoring the rich traditions of established practices.

This new developmental trajectory is made possible by substantial investments, which ultimately benefit the economy as a whole. In the last five years leading up to 2023, the European Union alone has invested over $300 billion to create a more favorable environment for start-up development. This massive injection of public funds is complemented by private investments, and these considerable financial resources have undeniably brought about economic benefits.

Innovative products and services introduced by start-ups significantly contribute to market growth and expand consumer choices. Start-ups are recognized as key drivers of innovation, which can lead to economic growth and diversification. According to Germany’s Federal Ministry for Economic Affairs and Climate Action, start-ups are critical to market growth and increasing competition through their introduction of new products and services (BMWK, 2017). By presenting ideas that challenge established industries, start-ups create new investment opportunities and facilitate industry development.

This cycle of innovation yields positive economic effects, including increased job opportunities and heightened competitiveness within various sectors. The emergence of new concepts and technologies from start-ups can invigorate markets, fostering healthy competition and improving consumer offerings. Through their inventive approaches, start-ups can profoundly influence economic expansion and prosperity, reshaping the landscape of future industries.

The market becomes more competitive with the entry of new players offering innovative products and services. Start-ups play a crucial role in driving economic dynamism through their creative strategies. By disrupting traditional market dynamics, they stimulate economic growth and foster innovation. This competition compels established companies to enhance their offerings, leading to a diverse array of consumer choices and improved quality.

Consumers benefit from a broader selection of products and services, as well as competitive pricing options. The presence of start-ups creates a more competitive market environment, resulting in greater overall value and quality for consumers. The competition instigated by start-ups not only benefits consumers but also contributes to economic advancement by promoting innovation and revitalizing the market.

According to Henry et al. (2020), circular start-ups can be classified into five distinct archetypes:

1. Design-based: These start-ups focus on product designs that require less material during production.
2. Waste-based: These ventures utilize waste as an input material for new products.
3. Platform-based: These include consumer-to-consumer marketplaces that facilitate the sharing or selling of pre-owned products.
4. Service-based: These start-ups replace ownership with access, allowing consumers to utilize services without needing to own the product.
5. Nature-based: These ventures leverage natural ecosystems for production without causing harm.

These categories cut across various industries, and it is possible for start-ups to incorporate multiple archetypes within a single venture.

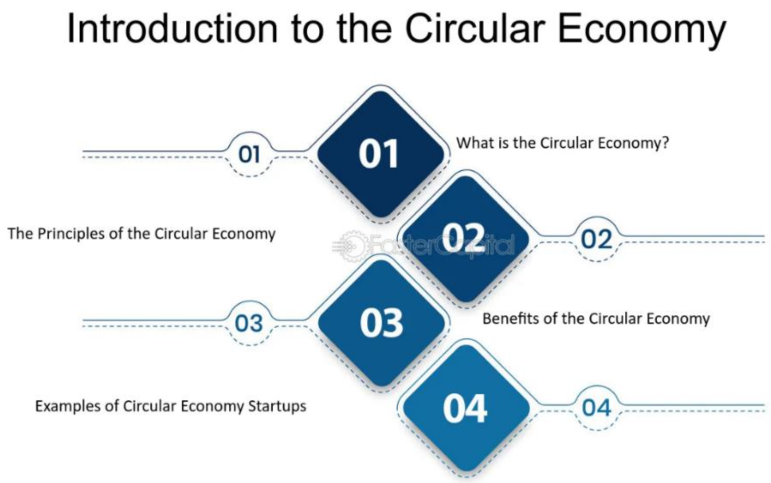

Figure 2: *Circular economy principles*

The idea of a circular economy is receiving considerable attention as a viable solution to the environmental issues we currently face. In contrast to the traditional linear economy, which operates on a "take, make, and dispose" model, the circular economy seeks to maximize the use of products and materials for as long as possible. This approach aims to minimize waste and enhance resource efficiency.

Principles of the Circular Economy.

To grasp the concept of the circular economy, it is crucial to understand its fundamental principles:

A. Eliminating Waste: The circular economy highlights the necessity of designing products and systems that reduce waste and pollution. This can be achieved by utilizing eco-friendly materials, adopting efficient manufacturing techniques, and creating products that are easy to repair, reuse, and recycle.

B. Keeping Products and Materials in Circulation: Rather than discarding items after their initial use, the circular economy promotes their refurbishment and reuse. By prolonging the lifespan of products, we can maximize their value and lessen the demand for new resources.

C. Restoring Natural Systems: The circular economy encourages the restoration and regeneration of natural resources. This encompasses sustainable practices like reforestation, water conservation, and the utilization of renewable energy sources.

Benefits of the Circular Economy.

Adopting the circular economy offers a variety of environmental and economic benefits, including:

A. Waste Minimization: By concentrating on waste prevention and recycling, the circular economy diminishes the volume of waste that ends up in landfills, thereby reducing environmental pollution and conserving natural resources.

B. Financial Savings: Implementing circular economy strategies can lead to significant cost reductions for businesses. For example, reusing materials and components can lower production expenses and decrease reliance on costly raw materials.

C. Job Creation: The circular economy has the potential to create new employment opportunities across various sectors, such as recycling, repair, and remanufacturing. This can foster economic growth and social advancement.

Examples of Circular Economy Startups

Many startups are emerging to facilitate the shift toward a circular economy. Here are a few noteworthy examples:

A. TerraCycle: This company specializes in recycling materials that are difficult to process. TerraCycle collaborates with major brands to collect and recycle items like cigarette butts, coffee capsules, and even chewing gum, transforming them into new products.

B. Grover: Grover offers a subscription-based rental service for electronics, allowing users to rent devices instead of buying new ones. This model promotes product reuse and helps reduce electronic waste.

C. ResQ Club: This app connects consumers with restaurants, cafes, and other food establishments to sell surplus food at discounted prices. By reducing food waste, ResQ Club supports the circular economy while providing affordable meals to customers.

In summary, the circular economy signifies a transformative shift toward a more sustainable and efficient economic model. By embracing the principles of the circular economy, businesses and individuals can aid in reducing waste, achieving cost savings, and restoring natural resources. Innovative startups are playing a pivotal role in advancing this transition and demonstrating the circular economy's potential to foster a more sustainable future.

Figure 3: *Circular start-ups*

Circular start-ups are poised to play a critical role in advancing the transition to a circular economy and achieving sustainability objectives. Their adaptability to shifting market dynamics and their inclination to adopt radical circular business models (CBMs) distinguish them from traditional firms. As a result, circular start-ups are expected to gain competitive advantages and excel in development and growth. However, similar to conventional start-ups, they may face significant barriers to scaling up.

Startups that are spearheading innovation in the circular economy frequently attract investment and support from a diverse range of stakeholders, including venture capitalists, impact investors, and government agencies. This financial backing is crucial as it empowers startups to scale their operations and bring their innovative solutions to market.

In conclusion, startups are pivotal in fostering innovation within the circular economy. Their fresh perspectives, agility, technology-driven approaches, and disruptive nature, combined with their capacity to attract investment, position them as key players in the quest for a more sustainable and circular economy. By investing in and supporting these startups, we can expedite the transition to a circular economy and pave the way for a more sustainable future.

1. Startups Offer Innovative Perspectives

Startups play a vital role in fostering innovation within the circular economy by providing fresh perspectives that challenge conventional thinking. Unlike established companies that often adhere to traditional practices, startups are unencumbered by these norms, allowing them to explore creative solutions. For instance, Circularity Capital, an investment firm based in London, actively supports startups focused on developing circular economy solutions. By channeling investment into these ventures, Circularity Capital contributes to advancing innovation and facilitating the transition toward a more sustainable circular economy.

2. Startups Are Agile and Adaptive

The agility and adaptability of startups are critical attributes that drive innovation in the circular economy. These companies are willing to take risks and experiment with new concepts, allowing them to pivot quickly when circumstances change. A prime example is RePack, a Finnish startup that has created a reusable packaging solution tailored for the e-commerce sector. By providing a sustainable alternative to conventional single-use packaging, RePack not only reduces waste but also promotes a more circular delivery system for goods.

3. Startups Utilize Technology for Innovation

Many startups harness advanced technology to propel circular economy innovations. They are designing cutting-edge solutions that employ data analytics, artificial intelligence, and automation to optimize resource utilization and minimize waste. For example, Optoro, a US-based startup, has created a software platform that assists retailers in managing and optimizing their product returns. By decreasing the volume of returned items that end up in landfills, Optoro plays a significant role in advancing the principles of a circular economy.

4. Startups Disrupt Traditional Industries

Startups have the potential to disrupt traditional industries and challenge established norms. Free from the constraints of legacy systems, they can introduce new business models that prioritize sustainability and circularity. A notable case is Too Good To Go, a Danish startup that has developed a mobile application connecting consumers with restaurants and grocery stores to rescue surplus food. By preventing food waste and establishing a market for surplus items, Too Good To Go disrupts the food industry and encourages a more circular approach to food consumption.

Abstract

The article studies the tools for improving the business processes of an enterprise. There are primary and auxiliary business processes at a manufacturing enterprise. The primary processes are those that result in the production of the main product (value), while all other processes are auxiliary. Thus, auxiliary processes include: service, management, and enterprise development processes. Attention is paid to the main areas of business process optimization, among which the following are highlighted: the minimum number of performers, the minimum involvement of managers, and the minimum number of control operations, and, in contrast to them, the maximum typing of processes, the maximum simplification of operations, and the maximum possible parallelism of business processes. The result of optimization of business processes at an enterprise is the elimination of unnecessary losses in the execution of processes that do not bring value to consumers, thereby achieving maximum satisfaction of needs, strengthening the position of the enterprise in the market, and ensuring the maximum inflow of profits to the enterprise.

Keywords: business model, business process, optimization, reengineering, benchmarking

I. Introduction

Establishing a profitable or at least break-even production process in the short term is an important issue. Given the aggravation of the economic crisis, which is now hindering the activities of manufacturing enterprises and leading to bankruptcy or forced cessation of business activities, the issue of optimizing the main and auxiliary production processes in order to exclude unproductive and unnecessary elements from the value chain, which would ensure the effectiveness of the business model, is becoming relevant.

The works of a large number of scientists are devoted to the study of issues of optimization of business processes of manufacturing enterprises [1-5, etc.]. The works pay attention to the problems of managing business processes of modern enterprises, forming strategies for overcoming crisis phenomena, consider resource management technologies based on the use of ERP systems, describe errors that occur in the process of optimizing the value chain of an enterprise. However, despite the sufficient elaboration of the issue, the problems of optimizing the main and auxiliary processes of manufacturing enterprises remain poorly studied, with the aim of eliminating unnecessary processes from the value chain and acquiring competitive advantages of the enterprise in the market.

The aim of the article is to study the directions of optimization of the main and auxiliary business processes of a manufacturing enterprise to improve the product value chain in the business model of a modern enterprise.

Business processes are understood as a set of interrelated actions, using appropriate technologies, making it possible to transform inputs (resources) into outputs (results) that are valuable to consumers and contribute to the growth of the enterprise value. A business process that ensures the achievement of the enterprise's business goals, expressed in quantitative and qualitative indicators used as optimization criteria, is considered optimal.

In general, the following set of business processes takes place at a manufacturing enterprise: main business processes, supporting (auxiliary), management and development processes.

II. Methods

The main business processes include processes during the implementation of which a product or service is created, in other words, added value that is valuable to the consumer. These processes are of great importance to the enterprise.

Supporting or auxiliary processes do not have strategic importance for the enterprise, they are engaged in maintaining the infrastructure, and their main consumers are the main processes. These processes can, if necessary, turn into main business processes, or, if competitive alternatives appear, can be outsourced.

Management and development processes represent the processes of managing the enterprise's activities, implementing the functions of planning, organizing, accounting, monitoring and regulating the main and auxiliary business processes. From the point of view of creating added value, such processes should be classified as auxiliary, since they also ensure the effective flow of the main processes.

Development processes are separate and are also considered auxiliary, since their task is to ensure the development of the enterprise and its product in the long term.

The given classification, in the author's opinion, is quite convenient, because it helps to understand the entire set of business processes occurring at the enterprise and optimize them by implementing effective management.

In 1985, M. Porter described a model of the enterprise value chain, which considers the entire enterprise as a set of interconnected business processes and allows for their optimization in order to reduce costs (business processes that do not represent value for the consumer) and generate profit.

III. Results

The value chain combines the primary and secondary processes of an enterprise in one circuit. The primary processes are represented by the production and distribution of the main product, and the secondary processes ensure the effective flow of the primary business processes.

Thus, within the framework of the value chain model with this approach, the following main business processes are distinguished: internal and external logistics, production, marketing and sales, as well as after-sales service.

Auxiliary business processes include: material and technical support, maintenance of enterprise infrastructure, human resource management, and development of the enterprise's technical and technological base.

The main characteristics of the enterprise business processes are:

– focus on the end consumer and "influence groups", thanks to which the process of realizing the produced value will take place;

– "process entry parameters" are the requirements that the consumer puts forward for the final product, namely the value for which the consumer is willing to pay;

– unsatisfied consumer demand at a certain point in time is the catalyst for the business process, and the satisfaction received from the product or service is its final stage;

– a business process consists of a set of interconnected processes and tasks, where the final result of one task is the beginning for the next, that is, a certain chain is created;

– each process executor unit acts as the executor of a certain range of work, however, sometimes they can be the executors of several types of processes;

– business processes are repetitive in time and space.

Optimization of business processes is extremely important for enterprises that provide services to consumers and have an extensive network of branches. These are, first of all, distributors, service enterprises, retail chains, etc. [4].

In general, optimization makes it possible to describe and link all business processes that are present at the enterprise for the purpose of regulating them, that is, defining the areas of responsibility of each employee or department to eliminate conflicts within the company, which will ensure their effectiveness. Only those processes that are often repeated should be optimized.

Optimization is relevant in the case of:

– the need to increase the company's transparency;

– change of the enterprise manager;

- sales of the enterprise;

- associations of enterprises.

The description of business processes becomes effective under the following conditions:

– if the company in which optimization is planned is small, since it is constantly changing its strategy, and therefore optimization may no longer be relevant and costly;

– if, on the contrary, the enterprise is quite large and has more than 5 thousand employees, in this case, optimization will be quite costly in terms of finances and time, since it requires the use of special technologies for describing business processes;

– in the absence of managers at the enterprise who would be responsible for organizing and adjusting business processes.

The main areas of business process optimization include:

1. Optimization of resource provision of the business process along the entire value chain of the enterprise, which is achieved through vertical and horizontal compaction of processes. Vertical compaction is possible due to the provision of independence to employees in decision-making (delegation of authority from the manager's area of activity) and leads to a reduction in the time for the process execution. Horizontal compaction is based on the use of labor of semi-skilled and broadly specialized workers who will specialize in the execution of a number of similar processes. This direction, on the one hand, allows avoiding a number of errors in the execution of business processes due to the minimization of performers, and on the other hand, helps to minimize information gaps, which, as a rule, slow down the flow of processes.

2. Minimal involvement of managers in the implementation of the business process – as practice shows, the involvement of a manager slows down the implementation of the business process, employees begin to lose independence, and affects the time and quality of the results obtained.

3. Elimination of unnecessary stages of conducting control operations of the business process. It is worth eliminating, if possible, intermediate control, which is carried out by the functional divisions of the enterprise during the implementation of the business process, but strengthening control over its results, which significantly optimizes the time of its implementation.

4. Application of such an important principle of production organization as parallelism. Currently, reducing the cycle of business process execution is a competitive advantage in the market, therefore, there is a need to execute most processes in parallel, which of course will complicate the business process itself, but will provide savings in time for its execution.

5. Implementation of typification of most processes. A high degree of typification of partial processes makes it possible to automate them and allows, having several algorithms for implementing the process, to determine typified scenarios for its flow.

6. Maximum simplification of processes to increase the ease of their execution, which will minimize the number of errors during the process and speed up the time of their execution.

7. Using benchmarking procedures to study best practices in organizing business processes. The essence of this method is to study the best experience in implementing business processes in order to transfer the main procedures, technologies, standards, and methods for implementing these processes to the activities of your own enterprise. The best representative of the industry is selected for the study and it is determined how this business process ensures profit generation, how costs are saved, the quality and competitiveness of products are ensured, etc.

As practice shows, when implementing benchmarking, the organization's managers may encounter various problems that create obstacles to effective benchmarking activities. Some problems are associated with improperly conducted research, and some - with insufficient motivation to adapt best practices. In addition to these, other problems may arise, for example, lack of resources, limited time, lack of necessary information about competitors, imperfect planning, insufficient skill level of employees, etc. However, despite the problems that may arise when conducting benchmarking, the successful results of its application by many leading organizations are evidence of its value and effectiveness.

Benchmarking is a specific technology that involves the implementation of five consecutive stages:

1. Planning. At this stage, the scope and objectives of benchmarking are determined to improve the organization's activities.

2. Data collection. This stage involves collecting the data needed for comparison, as well as determining the methodology for conducting the analysis.

3. Analysis. At this stage, the level of efficiency of two organizations is assessed: your own organization and the one selected for comparison.

4. Implementation. At this stage, a strategy and tactics for combating the organization's weaknesses that were identified during the comparison are formed.

5. Monitoring and evaluation. This stage involves calculating the relevant performance indicators in order to determine the impact of the implemented benchmarking activities on the main processes of the organization.

One of the important advantages of using benchmarking is that it has a positive impact on the innovative development of the organization, in particular [1]:

– promotes the generation of innovative ideas and their implementation;

– ensures increased efficiency and productivity of business processes;

– improves the quality of products and services provided by the organization;

– increases the motivation of employees to achieve new goals and organizational development. "As a result, the lack of effective change management can lead to the collapse of the organization" [3];

– contributes to the growth of the organization's competitive advantages in the market.

8. Business process reengineering. This approach is used to redesign existing processes that are likely to be poorly performing or are outdated and not generating profit. Reengineering requires the involvement of a team that will create a new business process without paying attention to the existing one.

9. Continuous improvement of business processes based on systematic analysis with the development of procedures for their improvement.

Partial methods of business process optimization include the following:

– optimization of the product portfolio, which is based on conducting marketing research and identifying products that provide the greatest inflow of profit to the enterprise;

– optimization of cash flows that do not contribute to obtaining profit in the planned amount and require changing the schedule of investments in low-income projects in order to eliminate gaps in cash flows between the receipt and expenditure of monetary resources;

– optimization of work with debtors, which includes revision of the terms of commercial credit in terms of payment terms and amounts;

– optimization of accounts payable, which can be carried out by methods of transferring part of the rights to ownership of assets in repayment of debt to creditors or transferring shares or a stake in the capital of an enterprise in exchange for receiving better conditions for attracting credit resources [5].

IV. Discussion

Let's look at a number of the main mistakes that business process managers and executives make during their optimization in an unfavorable economic situation:

– refusal or "freezing" of some projects that are aimed at the development of the enterprise, because the situation on the market will change, and development will have to be accelerated, which will lead to additional costs and possible losses of consumers, market share, etc.;

– lack of foresight and the closure of some areas of activity that are currently unprofitable, without waiting for the return on investment;

– savings on wages of key employees, reduction of bonuses and other additional payments;

– reduction of the number of employees through dismissal or transfer and a shorter working day [2].

The expected results of optimizing the enterprise's business processes include:

- reduction of the time for the execution of the entire business process, which is ensured by the reduction of the time for the execution of each partial process, due to the implementation of the principle of parallel execution and typification, because, as the practice of leading companies shows, the implementation of these measures helps to reduce the time for the execution of business processes by 20 - 200 times;

– reduction of downtime between operations of the main business process;

– reducing the duration of the business process leads to increased labor productivity of workers, acceleration of the turnover of the enterprise's capital and improvement of the enterprise's business activity, growth of the enterprise's market share and increase in profits;

– optimization of business processes ensures a reduction in their cost;

– maximum satisfaction of existing consumer needs is achieved;

– interaction between the functional divisions of the enterprise is improved by eliminating duplication of their responsibilities and reducing the time required for decision-making, etc.

Thus, modern trends in economic development put forward new requirements for the functioning of business models of manufacturing enterprises, which, in an attempt to maintain competitive positions in the market, must implement a number of measures to optimize their own business processes throughout the entire value chain for the end consumer.

It has been established that a business model consists of a number of business processes (partial elements), which in turn are divided into primary, auxiliary, management business processes and enterprise development processes. It has been proven that optimization of business processes is a necessary condition for enterprise survival in the market. The main directions of optimization of business processes of a business model of a manufacturing enterprise are presented, among which the most important are those that make it possible to reduce the costs of time and resources when performing each element of a business process, which ultimately leads to increased labor productivity, acceleration of the enterprise's capital turnover, reduction of production and commercial cycles, ensuring the generation of profit in the planned volume, maximum satisfaction of existing and potential consumer needs and an increase in the presence of the enterprise in a certain market niche.

Abstract

In recent years, commercial banks have been actively involved in financing projects related to the green economy, reflecting the global trend of transition to sustainable development.
Many banks are switching to electronic document management and using alternative energy sources for their operations. Despite the positive changes, banks face certain challenges. There is a risk that financing green technologies may negatively affect the performance of traditional companies. The State provides support commercial banks in the implementation of green economy projects.
The Bank of Russia and other government organizations are developing concessional lending programs that allow banks to provide loans on more favorable terms for projects aimed at sustainable development. This may include reducing capital reserve requirements for "green" projects, which makes them more attractive to banks. Commercial banks can receive subsidies to cover part of the interest rates on loans issued to finance environmentally friendly projects. This reduces the financial burden on borrowers and encourages them to implement sustainable initiatives. In some cases, Russian banks may cooperate with international financial institutions.
The implementation of green economy projects by commercial banks is not widespread enough. The successful development of green banking requires an integrated approach, including the adaptation of products, internal processes and corporate culture to new environmental standards. This study is devoted to an overview of the mechanisms and methods of stimulating and implementing green banking.

Keywords: green loans, green finance bonds, certification of green financial products, commercial banks, taxonomy of green projects

I. Introduction

Such instruments as green loans, green finance bonds and certification of green financial products serve the goals of widespread introduction of green banking financing. Green loans are becoming an important tool to support businesses striving for sustainable development and reducing their environmental footprint. Commercial banks are actively developing this area, offering a variety of products that can help both individual entrepreneurs and large companies. The objectives of financing green economy projects are green construction, environmentally friendly transport, waste management and much more.

Banks can act as organizers of the issue of green bonds by other companies, providing consulting services and helping with the placement of securities. In order to ensure transparency and investor confidence in green financial products of banks, their certification for compliance with the principles and standards of green finance.

Non–financial reporting of clients helps banks reduce the risks of implementing green financing projects and confirm a responsible approach to the implementation of green projects.

Non–financial reporting of banks helps to: establish trust from investors and customers, assess and manage risks; comply with international standards and expectations, which helps to increase their competitiveness in the market. Large Russian banks are already actively implementing non–financial disclosure practices. They publish reports containing not only statistical data, but also information about projects, initiatives and interactions with key stakeholders. This allows them not only to meet the requirements, but also to stand out from the competition. However, a large number of commercial banks have not yet introduced the usual practice of disclosing non–financial information.

Thus, it is relevant to research and develop mechanisms and methods to stimulate and implement green banking for implementation by commercial banks, including creating incentives for private investors and financial organizations.

The purpose of this study is to study the best practices of commercial banking financing of green economy projects and to develop mechanisms and methods for stimulating and implementing green banking for implementation by commercial banks.

The objectives of this study:

– conduct benchmarking of leading countries in the field of green banking, such as Germany, Sweden and The Netherlands, in order to identify the best practices for financing environmentally sustainable projects by commercial banks;

– to investigate the impact of government support on the activity of commercial banks in the field of green banking by analyzing the effectiveness of various subsidy mechanisms and tax incentives;

– compare the volumes and dynamics of green lending in the leading countries of Russia, identifying the key factors contributing to or hindering the growth of this segment;

– to assess the degree of involvement of commercial banks in sustainable development projects through a quantitative analysis of the structure of their loan portfolio and participation in green bonds.

II. Methods and materials

The research uses information data, as well as methods of theoretical research, namely: monographic.

III. Literature review

A lot of research has been devoted to green banking in a wide range of areas, including those that are the focus of this study. Thus, many authors emphasize that a significant amount of financial resources is needed to promote green projects, in which banks play a key role, acting as active participants in financing projects.

This includes the creation of a "green" banking system that unites various financial institutions, such as "green" banks and development banks. An important aspect is the need to regulate banking activities, including "green" financing, which should be supported by government politicians and banking regulators. This allows you to direct financial flows to sustainable projects and minimize environmental risks.

Some researchers notes that Russia, as a participant in the international environmental agenda, should actively develop the green finance market, taking into account international standards and practices. The paper points to the underdevelopment of the Russian financial market and the lack of active participation in international organizations, which may hinder this process. Success in the field of green finance can lead to attracting foreign investment and improving the country's reputation in the international arena.

Karpukhina (2020), Artemyev (2024) emphasize that banks, being financial intermediaries, cannot stay away from the implementation of ESG projects [1, 2]. However, a full understanding of the importance of the ESG agenda in the banking sector has not yet been achieved. The main factors slowing down development include the poor quality of information for analyzing borrowers.

IV. Results and discussion

The study showed that benchmarking of leading countries in the field of green banking, such as Germany, Sweden and the Netherlands represent a valuable area of research that can enrich Russian banking practice with the best global approaches.

However, despite their successes, the adaptation of this experience to the Russian economy it is associated with a number of challenges due to the peculiarities of the national context.

Germany, one of the largest economies in Europe, has demonstrated outstanding results in the field of green banking, especially in the framework of energy efficiency and renewable energy development programs. The main driver here is government support, expressed in large–scale subsidy programs, guarantees and benefits that make financing green projects more attractive to commercial banks. An important aspect is the participation of such large institutions as KfW Bankengruppe, which not only provides financial support, but also actively participates in the development of sustainable development strategies. This approach minimizes risks for banks and entrepreneurs, providing a high degree of confidence in the return on investment.

At the same time, the adaptation of the German green banking model presents certain difficulties for Russia. One of the key obstacles is the insufficient level of government support and subsidies for green projects, as well as the relatively weak development of renewable energy infrastructure. Unlike Germany, where a significant part of electricity is produced by wind and solar, in Russia the energy sector is still dominated by traditional hydrocarbons.

However, on the other hand, there is potential for growth in this segment, given Russia's rich natural resources, which can be used to transition to more sustainable energy supply models.

Sweden, being one of the most environmentally oriented countries, is actively developing green banking practices. Sweden is a leader in green bond issuance, which helps to raise significant funds to finance sustainable projects. Adapting the Swedish experience in Russia may also face certain difficulties. Firstly, the Russian green bond market is at the stage of formation, and the volume of issues is still significantly behind its Western counterparts. Secondly, the level of awareness and acceptance of ESG principles among Russian companies and banks remains low. Although interest in sustainability is growing, many companies still view ESG as an additional burden rather than an opportunity to create long–term value. Nevertheless, taking into account global trends and the growing interest of investors in sustainable financing, the introduction of ESG factors into Russian banking may become a strategically important area.

The Netherlands, in turn, demonstrates an innovative approach to green banking, actively developing new financial instruments and mechanisms, such as public–private partnerships. Dutch banks cooperate extensively with international financial institutions, which allows them to borrow best practices and integrate them into the national banking system. An important area is the financing of sustainable agriculture and water resources management, which corresponds to the natural and economic conditions of the country.

For Russia, where agriculture and water resources also play an important role, the experience of the Netherlands is of particular value. However, it should be borne in mind that the adaptation of these practices requires significant institutional changes and the development of new mechanisms for interaction between the state, banks and the private sector. Moreover, unlike the Netherlands, Russia faces problems of regional inequality, which can make it difficult to scale successful projects throughout the country. For example, successful green finance models in Central Russia may not be as effective in Siberia or the Far East. In the East, where the infrastructure is much less developed.

It is important to take into account that the successful adaptation of international practices requires an integrated approach, including not only the borrowing of specific financial instruments, but also the creation of an appropriate institutional environment, raising awareness and adoption of ESG principles, as well as the development of public partnerships with the private sector. In this context, the role of the state becomes key, since it is it that is able to set the vector of development and provide the necessary conditions for the growth of green banking in Russia. Fig.1 schematically shows the role of a commercial bank in the field of sustainable development.

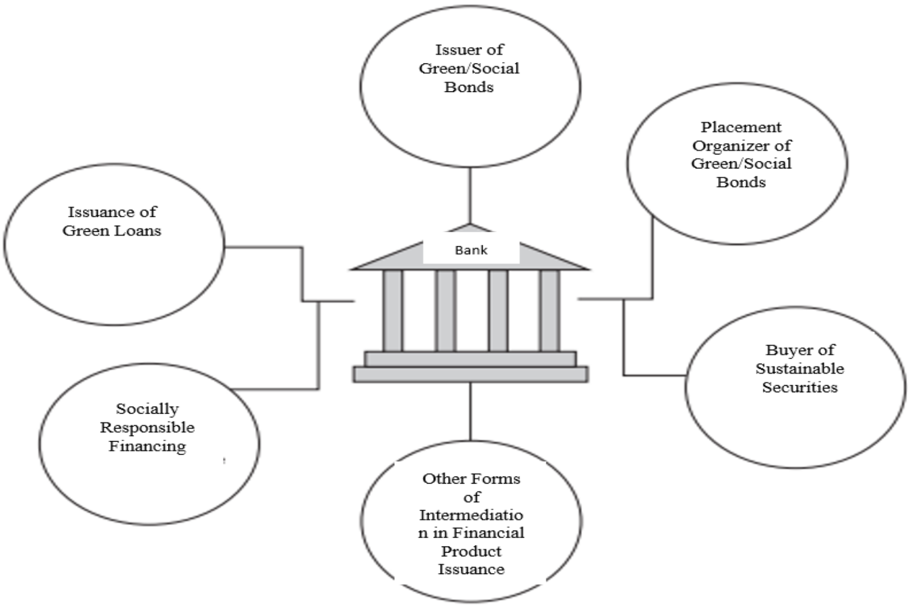

Figure 1: *The role of a commercial bank in the field of sustainable development*.
Source: according to the materials [3-15]

To quantify the impact of green finance on the financial results of commercial banks, a model based on regression analysis is proposed, which takes into account the volumes of green loans issued and green bonds issued in different countries.

The main estimation method is multiple linear regression, where dependent variables (ROA, ROE, profit) will be modeled depending on independent variables.

The obtained regression coefficients will allow us to assess how changes in the volume of green financing affect the financial results of banks. For example, a positive and significant value of the β1 coefficient will mean that an increase in the volume of green loans contributes to an increase in the profitability of the bank's assets. Control variables can be added to the model, such as the total assets of the bank, interest rates, and the economic situation in the country, in order to take into account external factors that can also affect financial results. After evaluating the model, hypotheses about the importance of green finance for banks' financial performance can be tested.

Also, based on the model, it is possible to make forecasts and assess how an increase in green financing may affect the bank's future results. It is important to keep in mind that the volume of green loans and bonds in Russia is still small compared to other countries, which may reduce the importance of regression coefficients. However, as the green banking sector grows, the model may become an important tool for evaluating the effectiveness of such investments and developing strategies for Russian commercial banks. In order to ensure the rapid growth of the green banking sector, state support for the activity of commercial banks in the field of green banking is necessary, including various mechanisms of subsidies and tax incentives.

Financial institutions are facing new challenges and requirements, and the effectiveness of various subsidy mechanisms and tax incentives is becoming a determining factor for the successful integration of green finance principles into the banking sector. One of the main instruments of government support is subsidizing interest rates on green loans. In a number of countries, such as Germany and France, this mechanism has proven to be highly effective.

In turn, this makes such projects more attractive to commercial banks, reducing their risks and increasing their potential profitability. An example of the successful implementation of this approach is the program implemented in Germany through KfW Bankengruppe, which provides subsidies and guarantees to green projects.

Tax incentives are another important mechanism of state support that can stimulate the development of green banking. In countries such as Sweden and the Netherlands, tax incentives are provided not only to enterprises implementing green projects, but also to banks actively involved in financing such initiatives.

However, at the moment their use remains limited, which reduces the motivation of banks to participate in green projects. The introduction of systemic tax incentives for banks supporting sustainable development could It would significantly increase their interest in expanding green lending and issuing green bonds. This, in turn, would create conditions for increasing investments in projects aimed at environmental modernization and reducing the carbon footprint.

Despite the obvious advantages of government support, it must be borne in mind that its effectiveness depends not only on the scale of subsidies and benefits, but also on the quality of program implementation.

It is important to ensure transparency and accessibility of support mechanisms so that they really contribute to the growth of green banking, and do not create additional barriers for commercial banks.

The development of green lending in the world today is determined by many factors that differ in their importance and impact on the financial results of banks and the economy as a whole.

Comparing the volumes and dynamics of green lending in leading countries such as Germany, Sweden and the Netherlands with the situation in Russia allows not only to assess the current state of affairs. Such criteria include institutional support, the development of a regulatory framework, the level of awareness of the importance of ESG principles.

Over the past decades, Germany, Sweden and The Netherlands has consistently strengthened its position in the field of green lending, which has led to significant successes in this area. In Germany, the volume of green loans annually shows steady growth exceeding 15–20 %.

Which, through state–owned banks such as KfW, provides subsidies and guarantees for green projects, the development of renewable energy sources and sustainable construction. This allows banks to reduce their risks and attract more customers interested in sustainable development. In Sweden, the dynamics of green lending is also impressive, with an annual increase of 12–18 %, and the share of green loans in the total loan portfolio of Swedish banks is 10–12 %.

This was achieved through the active integration of ESG principles into banking practice and government support in the form of tax incentives and special financing programs. The Netherlands shows similar results, with green lending growing at 10–15% per year and significant investment in projects related to sustainable agriculture and water management. At the same time, the Russian green lending market lags far behind its Western counterparts. The volume of green loans in Russia is less than 1% of the total loan portfolio of banks, and the growth rate remains modest, ranging from 5–7 % per year.

These indicators indicate a significant lag, which requires an analysis of the factors hindering the growth of green lending in the country. One of the key barriers is insufficient institutional support. While in In Germany and Sweden, state–owned banks play an active role in stimulating green lending, while such mechanisms have not yet become widespread in Russia. The availability of subsidy programs is limited and access to them is difficult, which constrains banks' interest in this segment. Another important factor is the regulatory framework. Leading countries have long developed and implemented clear standards and taxonomies for green projects, which ensures transparency and reduces risks for market participants.

In Russia, such a regulatory framework is still being formed, and the lack of clear criteria creates uncertainty for both banks and investors. This leads to the fact that banks are afraid to participate in green lending due to high risks and uncertain prospects for return on investment. In addition, the level of awareness about the importance of ESG principles in Russia remains low. In Germany and Sweden, environmental responsibility and sustainable development have long been an integral part of banks' corporate culture and strategy. In these countries, customers and investors are aware of the importance of sustainable development and require banks to meet high standards. In Russia ESG principles are still perceived as additional requirements rather than an opportunity to create long–term value. This hinders the development of green lending, as demand for such products remains limited.

In Sweden and the Netherlands, tax incentives and other financial instruments create additional incentives for banks interested in developing green finance. There are practically no such benefits in Russia, which reduces the motivation of banks to participate in green projects.

Global trends in sustainable development, international commitments to reduce carbon emissions and growing investor interest in sustainable projects create prerequisites for the activation of this segment. The introduction of successful practices from other countries, the adaptation of the regulatory framework, increased government support and increased awareness of the importance of ESG principles can be key factors contributing to the growth of green lending in Russia.

Thus, a comparative analysis of the volumes and dynamics of green lending in leading countries and Russia shows that the successes of most countries in this area are achieved thanks to a well–structured system of institutional support, a developed regulatory framework, a high level of awareness of the importance of ESG principles and the availability of economic incentives. In Russia, on the contrary, insufficient government support, a weak regulatory framework, a low level of acceptance of ESG principles and a lack of significant economic incentives are the main barriers.

The growth rate of green loans – an analysis of changes in the volume of green loans in dynamics allows us to assess how actively the bank is expanding its sustainable financing programs. Sustained growth indicates a strategic focus on sustainable development.

The analysis requires collecting the following data: the total volume of the bank's loan portfolio, the volume of green loans issued, the volume and number of green bond issues.

The methodology for analyzing green finance should include both retrospective and forward–looking approaches.

The forward–looking approach includes modeling the future growth of green lending based on current trends and evaluating possible market development scenarios. This approach will make it possible to determine which measures can stimulate an increase in the share of "green" loans in the loan portfolio and how actively banks are ready to support the transition to sustainable development. An equally important aspect of the engagement assessment is the analysis of the participation of Russian banks in the issuance of "green" bonds. Green bonds are debt instruments designed to finance environmentally sustainable projects. Participation in the issuance of such bonds indicates that the bank not only supports sustainable development at the lending level, but also actively participates in raising capital for the implementation of environmental initiatives through the capital market.

It is important to note that participation in the issue of green bonds can be either direct, when the bank itself acts as an issuer, or indirect, when the bank supports the issue of third parties by providing guarantees or acting as an organizer of the issue. To quantify the involvement of

Russian banks in green bonds, it is necessary to analyze the structure of their investment portfolio and determine what share green bonds occupy in it.

Thus, for a comprehensive assessment, it is necessary to analyze not only the volume of bond issuance, but also the structure of the use of borrowed funds. It is also interesting to consider the degree of involvement of Russian banks in international partnerships and projects related to sustainable development. Within the framework of such projects, banks can not only improve their skills in the field of green finance, but also gain access to best practices and technologies that can be adapted for use in the Russian market. This is especially important in the context of the growing global trend towards increased regulation and accountability in the field of sustainable development.

Banks that actively implement ESG principles in their activities have a higher ability to adapt to changing market conditions. Therefore, in order to increase the involvement of Russian banks in sustainable development projects, it is necessary not only to expand credit programs and issue green bonds, but also to invest in the development of internal competencies and corporate culture focused on the principles of sustainable development.

Thus, a quantitative analysis of the loan portfolio structure and participation in green bonds allows a deeper understanding of the degree of involvement of Russian commercial banks in sustainable development projects. This, in turn, opens up opportunities for further development of this segment and integration of the principles of sustainable development into banking activities on a long–term basis.

This will not only attract capital to finance environmentally significant projects, but also strengthen the bank's reputation as a sustainable financial institution. The implementation of a monitoring and reporting system for green projects will ensure transparency of the bank's activities and strengthen the trust of investors and customers. In addition, providing technical assistance and advice to clients on sustainable development issues will help them better understand the requirements of green finance and increase their willingness to participate in such projects.

It is necessary to adapt international standards of green finance to Russian conditions, taking into account the specifics of the national market. At the same time, it is necessary to actively raise awareness and train the bank's staff on sustainable development issues, which will allow banks to work more effectively with environmentally significant projects. An important aspect is also the introduction of tax incentives for clients implementing projects in the field of sustainable development. This may include benefits and subsidies that will help make green finance more affordable. The active involvement of private investors and the expansion of cooperation with government support programs are also important elements of the strategy for adapting international best practices.

V. Conclusion

Supporting the development of infrastructure for green finance, including project verification and certification systems, will also be an important step towards strengthening the position of Russian banks in this area. Participation in educational and information campaigns on sustainable development issues will help banks not only strengthen their reputation, but also raise public awareness of the benefits of green financing. It is also important to develop non–financial disclosure practices, including sustainability indicators, which will allow banks to meet international standards and investor expectations.

Thus, green projects and Green Banking in Russia are at the stage of formation, which is manifested in the relatively low share of green loans and bonds in the total portfolio of commercial banks. Nevertheless, global trends and international commitments stimulate the growth of interest in sustainable financing, which creates prerequisites for the accelerated development of this segment.

Abstract

The transition to a low-carbon economy is a crucial strategy in combating climate change and promoting sustainable development. This shift not only aims to reduce greenhouse gas emissions but also offers substantial socioeconomic benefits. Firstly, the move towards a low-carbon economy generates new job opportunities in renewable energy sectors, energy efficiency initiatives, and sustainable transportation systems, thereby driving economic growth. For instance, investments in green technologies can create a diverse range of employment options, from research and development to manufacturing and installation. Secondly, transitioning to clean energy sources decreases dependence on fossil fuels, which enhances energy security for nations and regions. By diversifying energy supply and investing in local renewable resources, countries can mitigate the risks associated with fluctuating fossil fuel prices and geopolitical tensions. Moreover, the reduction of environmental pollution resulting from a low-carbon economy leads to significant public health improvements. Cleaner air and water translate into lower healthcare costs and increased productivity among workers, as health-related absences decrease. Additionally, investing in low-carbon technologies promotes the development of sustainable cities and communities, which improves residents' quality of life through better public transport, green spaces, and healthier living conditions. Furthermore, transitioning to a low-carbon economy supports innovation and technological advancements. By fostering research and development in sustainable technologies, countries can position themselves as leaders in the emerging green economy, creating further economic opportunities. This transition also aligns with global climate agreements and sustainability goals, enhancing a nation's reputation and attracting investment.

Keywords: energy security, public health, quality of life, environmental sustainability, innovation, green economy, climate change, sustainable development, economic growth

I. Introduction

The transition to a low-carbon economy is becoming increasingly critical in the face of escalating climate change and environmental degradation. This paradigm shift aims to reduce greenhouse gas emissions by transforming traditional energy systems and adopting sustainable practices across various sectors, including industry, transportation, and agriculture. The urgency for action has been underscored by international agreements, such as the Paris Agreement, which seek to limit global warming to well below 2 degrees Celsius.

Transitioning to a low-carbon economy presents a unique opportunity not only to address environmental challenges but also to foster significant socioeconomic benefits. As governments, businesses, and communities strive to implement cleaner technologies and sustainable practices, they open avenues for job creation, economic diversification, and improved public health outcomes. This transformation aligns with broader objectives of sustainable development, promoting a balanced approach that integrates economic growth with environmental stewardship.

The potential for job creation is particularly noteworthy. Investments in renewable energy sources, energy-efficient technologies, and sustainable transportation infrastructure are expected to generate millions of jobs globally. These sectors are labor-intensive and can provide employment opportunities in both urban and rural areas, enhancing economic resilience and reducing inequality.

Moreover, a low-carbon economy contributes to energy security by reducing reliance on fossil fuels, which are subject to price volatility and geopolitical tensions. By investing in renewable energy and local resources, countries can enhance their energy independence, stabilize energy prices, and promote local economic growth.

The environmental benefits of this transition are equally compelling. Reducing greenhouse gas emissions leads to improved air and water quality, resulting in better public health outcomes and reduced healthcare costs. Healthier populations contribute to increased productivity, benefiting economies at large. In light of these considerations, this paper explores the socioeconomic benefits of transitioning to a low-carbon economy. It highlights the interconnectedness of environmental sustainability and economic development, emphasizing the need for integrated policy approaches that promote innovation, job creation, and improved quality of life. By examining these benefits, the paper aims to provide insights into the critical role that a low-carbon economy can play in fostering a sustainable future for individuals and communities worldwide.

II. Methods

This study employs three primary methods to analyze the socioeconomic benefits of transitioning to a low-carbon economy:

1. **Literature Review:** A comprehensive literature review was conducted to gather and analyze existing research on the socioeconomic impacts of low-carbon initiatives. This review included academic journals, government reports, and case studies from various countries. By synthesizing findings from these sources, the study identifies key themes, trends, and potential gaps in the understanding of how transitioning to a low-carbon economy affects job creation, public health, and economic growth.
2. **Case Studies:** In-depth case studies were performed on specific countries or regions that have successfully implemented low-carbon strategies. These case studies highlight real-world examples of the socioeconomic benefits associated with the transition, focusing on metrics such as job creation in renewable energy sectors, improvements in public health outcomes, and overall economic growth. Analyzing these case studies provides valuable insights into effective practices and policies that can be replicated in other contexts.
3. **Surveys and Interviews:** Surveys were conducted with stakeholders, including policymakers, business leaders, and community members, to gather qualitative and quantitative data on perceptions and experiences related to the low-carbon transition. In addition, semi-structured interviews with experts in renewable energy and environmental economics were carried out to provide deeper insights into the challenges and opportunities associated with low-carbon initiatives. This method helps to capture diverse perspectives and enriches the analysis of socioeconomic impacts.

By utilizing these three methods, the study aims to provide a well-rounded understanding of the socioeconomic benefits of transitioning to a low-carbon economy.

III. Results

The digital economy is crucial in facilitating unprecedented access to information. With the rise of digital technologies and the widespread availability of the internet, individuals, organizations, and communities can now easily and efficiently tap into a vast range of information. The significance of the digital economy in information access can be illustrated through several key points:

1. **Democratization of Information:** The digital economy has democratized information access, dismantling traditional barriers and enabling people from various backgrounds to gain knowledge. Previously, access was often restricted to those in privileged positions. Today, the digital economy has leveled the playing field, empowering individuals regardless of their location, socioeconomic status, or educational background.
2. **Connectivity and Global Reach:** The digital economy allows for global access and sharing of information. The internet has interconnected individuals from around the world, enabling rapid information dissemination and exchange across borders. This interconnectedness fosters cross-cultural understanding, collaboration, and the sharing of diverse viewpoints.
3. **Abundance and Variety of Information:** The digital economy has generated a wealth of information in multiple formats, including text, images, audio, and video. Online platforms, search engines, and digital libraries provide extensive repositories of knowledge on a wide array of topics. This information wealth allows individuals to explore, learn, and remain informed about subjects that interest them, encouraging personal growth and lifelong learning.
4. **Timeliness and Real-time Updates:** The digital economy ensures that information is accessible in real time. News websites, social media platforms, and online publications deliver immediate updates on current events, allowing individuals to stay informed about the latest developments globally. Real-time access to information is essential in various fields, such as emergency response, financial markets, and scientific research.
5. **Customization and Personalization:** The digital economy offers personalized access to information tailored to individual preferences and needs. Recommendation algorithms and personalized content delivery systems adjust information to align with users' interests, providing a more relevant and engaging experience. This customization enhances individuals' ability to acquire knowledge in a focused manner.
6. **Open Educational Resources:** The digital economy has facilitated the development and distribution of open educational resources (OERs). OERs are freely available educational materials accessible online, including textbooks, lecture notes, multimedia resources, and interactive learning platforms. These resources broaden access to education and lifelong learning, making high-quality educational content available to a wider audience.

In summary, the digital economy has transformed access to information by democratizing knowledge, providing global connectivity, offering a wealth of information, delivering real-time updates, enabling personalization, and promoting open educational resources. Its role in information access is vital for empowering individuals, fostering continuous learning, and creating a more informed and connected global society.

IV. Discussion

While the digital economy holds significant promise for sustainable development, it also poses several challenges that must be addressed. One major issue is the digital divide, which refers to the disparity between those who have access to digital technologies and the internet and those who do not. In many areas, especially low-income regions and marginalized communities, access to digital infrastructure and internet connectivity is limited or nonexistent. This gap restricts equal participation in the digital economy, exacerbates existing inequalities, and limits access to information, education, and economic opportunities.

Another concern is the environmental impact of the digital economy. The rising demand for digital devices, data centers, and cloud computing infrastructure contributes to significant energy consumption and the generation of electronic waste. The production, use, and disposal of electronic devices lead to resource depletion, carbon emissions, and hazardous waste. It is essential to balance the advantages of the digital economy with its environmental impacts to ensure sustainable development.

Additionally, the rapid pace of technological advancement and the shorter lifecycle of digital devices contribute to the escalating issue of electronic waste (e-waste). E-waste contains hazardous materials that can harm both the environment and human health if not properly managed. Effective e-waste management systems, including recycling and responsible disposal practices, are vital to mitigate the negative environmental and health impacts associated with electronic waste.

Moreover, the digital economy heavily relies on the collection, storage, and utilization of personal data, raising privacy and security concerns. This reliance poses risks related to the potential misuse or unauthorized access to sensitive information. Furthermore, the increasing interconnectedness of digital systems makes them susceptible to cyber-attacks and security breaches.

The digital economy also introduces ethical considerations regarding the responsible use of technology and data. Issues such as algorithmic bias, digital surveillance, and the implications of automation for jobs and labor markets require careful attention. Striking a balance between technological advancement and ethical considerations is crucial to prevent unintended negative consequences and promote fairness and social inclusion.

Effective participation in the digital economy necessitates individuals possessing the requisite skills and digital literacy. However, many individuals, particularly those from disadvantaged backgrounds or older generations, may lack the necessary skills and knowledge. Bridging the digital skills gap and promoting digital literacy programs are essential for ensuring inclusive access and equal opportunities for all.

Addressing these challenges demands a collaborative approach involving multiple stakeholders, including governments, businesses, civil society organizations, and international bodies. Policies and regulations should be established to bridge the digital divide, promote sustainable practices within the digital economy, safeguard privacy and security, and uphold ethical considerations. Additionally, investing in digital infrastructure, education, and capacity-building programs can empower individuals and communities to leverage the benefits of the digital economy for sustainable development.

Several obstacles hinder the digital economy's role in achieving sustainable development. Poor infrastructure in many regions and countries can impede effective communication and IT development. Slow internet speeds and a lack of network coverage significantly hinder the growth of the digital economy and sustainable development efforts. Furthermore, many individuals and organizations struggle to acquire the digital skills necessary to engage fully in the digital economy. Providing training and continuing education opportunities is essential to enhance digital skills and empower people to utilize digital technology effectively.

Existing legislation and policies can also obstruct the development of a sustainable digital economy. Legal and regulatory constraints may hinder innovation and investment in the digital sector, necessitating the creation of policies that encourage technological development while promoting resilience and innovation. Cultural and social challenges further complicate this issue, as some communities may resist adopting digital technology due to mistrust or lack of awareness of its benefits. Promoting awareness and education about the digital economy can help foster acceptance and usage in these communities.

To realize the digital economy's potential in achieving sustainable development, it is crucial to promote innovation and entrepreneurship. Technological innovation can drive sustainable development by developing new digital technologies and solutions that enhance resource efficiency and improve economic and environmental outcomes. Supporting digital entrepreneurship stimulates innovation and sustainable development. Creating a favorable environment for startups and innovators in the digital sector can lead to job creation, improved productivity, and enhanced innovation.

Financial assistance and resources are necessary for startups and innovators in the digital sector. This includes investment funding, government programs aimed at promoting entrepreneurship, and training and technical assistance to nurture innovation and growth among startups contributing to sustainable development. Finally, strengthening collaboration between the public sector, private sector, and civil society is vital to achieving sustainable development through the digital economy. Sharing knowledge and experiences can enhance integration and collective efforts toward sustainability.

By addressing these challenges and promoting innovation, the digital economy can play a transformative role in achieving sustainable development goals.

The transition to a digital economy presents both opportunities and challenges in the pursuit of sustainable development. The interplay between digital technologies and sustainability underscores the need for a nuanced understanding of how these tools can be leveraged to foster economic growth while minimizing environmental impact and enhancing social equity.

One of the most promising aspects of the digital economy is its capacity to democratize access to information. By breaking down traditional barriers, individuals from various backgrounds can gain access to knowledge and resources that were previously out of reach. This democratization fosters greater participation in the economy and society, potentially leading to a more equitable distribution of opportunities. However, it is crucial to recognize that not everyone benefits equally from this access. The digital divide remains a significant obstacle, particularly in low-income regions and marginalized communities where internet connectivity is limited. Bridging this divide requires targeted interventions, such as investment in infrastructure and digital literacy programs, to ensure that all individuals can participate fully in the digital economy.

The environmental impact of the digital economy is another critical issue that requires careful consideration. While digital technologies can enhance efficiency and reduce resource consumption in some sectors, they also contribute to energy consumption and electronic waste. For instance, the proliferation of data centers and the demand for electronic devices can lead to significant carbon emissions and resource depletion. As a result, it is imperative to adopt sustainable practices within the digital economy, including promoting energy-efficient technologies and effective e-waste management systems. Policymakers must find ways to balance the benefits of digital innovation with its environmental consequences, ensuring that sustainable development goals are met without compromising ecological integrity.

Privacy and security concerns are also paramount in the digital economy. The reliance on personal data collection and storage raises questions about data protection and the potential for misuse. Ensuring robust privacy regulations and enhancing cybersecurity measures are essential to build trust among users. Without addressing these concerns, the potential benefits of the digital economy may be overshadowed by public apprehension and resistance to adopting new technologies.

From an ethical standpoint, the digital economy raises important questions about fairness and inclusion. Issues such as algorithmic bias and the implications of automation on employment necessitate careful scrutiny. Policymakers and stakeholders must engage in ongoing dialogues about the ethical implications of digital technologies, fostering practices that promote equity and social inclusion. This is particularly important in light of the potential for automation to displace workers, which could exacerbate existing inequalities if not addressed proactively through retraining and upskilling initiatives.

Skills and digital literacy are fundamental to maximizing the benefits of the digital economy. Individuals who lack the necessary skills to navigate digital platforms may find themselves at a disadvantage, unable to participate fully in the opportunities presented by digital technologies. Addressing this skills gap requires a concerted effort from educational institutions, governments, and private sectors to develop training programs that equip individuals with the tools they need to thrive in a digital world.

Collaboration among various stakeholders is critical to overcoming the challenges posed by the digital economy. Governments, businesses, civil society, and international organizations must work together to create an inclusive digital landscape that fosters innovation and entrepreneurship. By promoting partnerships and knowledge sharing, stakeholders can better address the complexities of the digital economy and drive sustainable development efforts.

Finally, promoting innovation and entrepreneurship in the digital sector is essential for unlocking the potential of the digital economy. Encouraging the development of new technologies and solutions can lead to improved resource efficiency and economic growth. Providing financial support and resources for startups can stimulate innovation and create jobs, further enhancing the positive impact of the digital economy on sustainable development.

In summary, the digital economy offers significant potential for sustainable development, but it also presents a set of challenges that require careful consideration and proactive measures. By addressing the digital divide, mitigating environmental impacts, safeguarding privacy, promoting ethical practices, and enhancing skills and collaboration, we can harness the transformative power of the digital economy to create a more sustainable and equitable future.

Abstract

Compiling a list of aquatic plants of the Chechen Republic is very important from an ecological point of view. The main goal of this study was to provide a detailed list of aquatic plants growing on the territory of the republic. Aquatic plants play an important role in water systems. This work presents a systematic and biomorphological analysis, as well as the occurrence of aquatic plants of the Chechen Republic. This study is an inventory and analysis of the aquatic flora of the republic. These studies were conducted based on the processing of herbarium materials and the authors' own observations. Aquatic vegetation forms the basis of aquatic ecosystems, providing habitats, food, and oxygen for a wide range of aquatic organisms, from invertebrates and fish to larger predators. Moreover, aquatic plants contribute to water purification by filtering pollutants and stabilizing sediments, thus playing a key role in maintaining water quality. The primary objective of this study was to compile a comprehensive list of aquatic plants growing in the various water bodies across the Chechen Republic and to analyze their occurrence, distribution, and ecological roles. This work involved both a systematic and biomorphological analysis of the region's aquatic flora, along with an assessment of how these plants are distributed across different habitats.

Keywords: Chechen Republic, water, aquatic plants, species, genus, family, biomorph, hemicryptophytes, cryptophytes, therophytes, occurrence

I. Introduction

Chechen Republic is located V moderate climate belt, what provides big diversity And wealth flora. In the northern part of the Chechen Republic, the semi-desert turns into steppe, the territories close to the central part change from forest-steppe to forest. Between the belt of forests and snowy peaks there are subalpine and alpine meadows. Thus, the territory of our republic is very diverse in climatic terms, due to which plant forms have great geographic plasticity [5].

Water, the most important resource for sustaining life on our planet, is of critical importance to both humans and the ecosystem as a whole. A number of factors, including population growth, rapid industrialization, urbanization, and unsustainable use of natural resources, have significantly affected water quality in recent decades.

Aquatic plants play an important role in aquatic systems. A comprehensive understanding of their spatial distribution can help in developing biodiversity conservation plans.

II. Methods

Aquatic plants are perennial (less often annual) plants, the necessary condition of life of which is full or partial stay in fresh (mostly), salt or brackish water. Aquatic plants are mostly represented by herbs.

The purpose and objectives of the study. The purpose of the work is to conduct a systematic, biomorphological, and also an analysis of the occurrence of aquatic plants in the Chechen Republic.

III. Results

In the study of the flora, the material obtained during the field research and observations of the authors, as well as information obtained during the study of the herbarium collections of "Botany, Zoology and Bioecology" was used. Chechen State University named after A.A. Kadyrov.

This study presents aquatic plants of the Chechen Republic that have economic significance. As a result of the study, a total of 78 plant species were registered, united into 28 different families. It was established that the dominant families are Cyperaceae, Poacea, and Buckwheat [7] .

The complete list is presented in Table 1. Their numerical ratio is shown in Fig.1.

Table 1: *Systematic analysis of aquatic plants of the Chechen Republic*

No.	Family	Genus	View
1.	*Equisetaceae* Rich. ex DC. – Horsetail	*Equisrtum*	*Equisrtum arvense* L. – Field Horsetail
			Equisrtum fluviatile L. (*E. heleocharis* Ehrh.) – Marsh horsetail
2.	*Marsileaceae* Mirb. – Marsileaceae	*Marsilea*	*Marsilea quadrifolia* L. – Marsilea quadrifolia
3.	*Salviniaceae* Lest. – Salviniaceae	*Salvinia*	*Salvinia natans* (L.) All.– Floating salvinia
4.	*Iridaceae* Juss. –Iridaceae (Iridaceae)	*Iris*	*Iris pseudacorus* L. – Iris (Iris) yellow
5.	*Droseraceae* Salisb. – Sundews	*Drosera*	*Drosera rotundifolia L.* – Round-leaved sundew
6.	*Trapaceae* Dumort. – Chilimaceae (Cornworts)	*Trapa*	*Trapa hyrcana* Woronow – Chilim Hyrcana
7.	*Ranunculaceae* Juss. – Buttercups	*Ranunculus*	*Ranunculus sceleratus* L. – Poisonous Buttercup
			Ranunculus repens L. – Creeping Buttercup
		Aquilegia	*Aquilegia caucasian* Bieb . (*A. olympica* Boiss .) – Caucasian columbine
8.	*Butamaceae* Rich. – Susakovyh	*Butomus*	*Butomus umbellatus* L. – Umbrella susak
9.	*Brassicaceae* Burnett *(Cruciferae)* – Cabbage (Cruciferae)	*Rorippa*	*Rorippa barbareifolia* (DC.) Kitag. *(R. islandica* (Oed.) Schinz et Thell; *R. palustris* (Leyss.) Bess. *)* – Icelandic watercress
			Rorippa austriaca (Crantz) Bess. – Austrian watercress

10.	*Rosaceae* Juss. – Pink	*Potentilla*	*Potentilla supina* L. – Low cinquefoil
			Potentilla reptans L. – Creeping cinquefoil
11.	*Lythraceae* J.St.- Hil. – Lythraceae	*Lythrum*	*Lythrum salicaria* L. – Willow-leaved loosestrife
12.	*Hypericaceae* Juss. - St. John's wort	*Hypericum*	*Hypericum quadrangulum* L. (*N. tetrapterum* Fries; *N. acutum* Moench. now. illegit.) - 3 willow four-winged
13.	*Onagraceae* Juss. – Willowherb (Nickweed)	*Epilobium*	*Epilobium palustre* L. – Fireweed
14.	*Apiaceae* Lindl. – DonkeyCelery (Umbelliferae)	*Berula*	*Berula erecta* (Huds.) Cov. *(Sium erectum Huds.)* – Berula straight
15.	*Polygonaceae* Juss. – Buckwheat	*Rumex*	*Rumex patientia* L. – Spinach sorrel
		Polygonum	*Polygonum amphibium* L – Amphibian knotweed
			Polygonum hydropipe L - Water pepper, water pepper
			Polygonum lapathifolium L. – Buckwheat (Polygonum) sorrel-leaved
			Polygonum persicaria L – Buckwheat
16.	*Primulaceae* Vent. – Primroses	*Samolus*	*Samolus valerandi* L. – Northerner Valeranda
		Lysimachia	*Lysimachia vulgaris* L. – Common loosestrife
17.	*Apocynaceae* Juss . – Apocynaceae	*Trachomitum*	*Trachomitum sarmatiense* Woodson – Sarmatian kendyr
18.	*Laimiaceae* Until. – Lamiaceae (Labiatae)	*Scutellaria*	*Scutellaria galericulata* L. – Skullcap
		Lycopus	*Lycopus europaeus* L. – European watercress
		Menta	*Mentha caucasica* Yand. – Caucasian mint (long-leaved)
			Mentha aquatica L. – Water mint
19.	*Scrophulariaceae* Juss. – Norichnikovye	*Veronica*	*Veronica anagallis-aquatica* L. – Spring Veronica
			Veronica beccabunga L . – Veronica potochnaya
20.	*Asteraceae* Dumort . (*Comnositae*) – Asteraceae (Compositae)	*Eupatorium*	*Eupatorium cannabinum* L. – Eupatorium hemp-like
		Bidens	*Bidens tripartite* L. – Three-part succession
		Sonchus	*Sonchus palustris* L. – Marsh sow thistle
21.	Typhaceae Juss . – Cattails	*Typha*	*Typha latifolia* L. (*T. shulttleworthii* C. Koch et Sond .) – Broadleaf cattail
			Typha angustifolia L. – P ogoz angustifolia

			Juncus inflexus L. – Inflexible rush
Total:		47	78

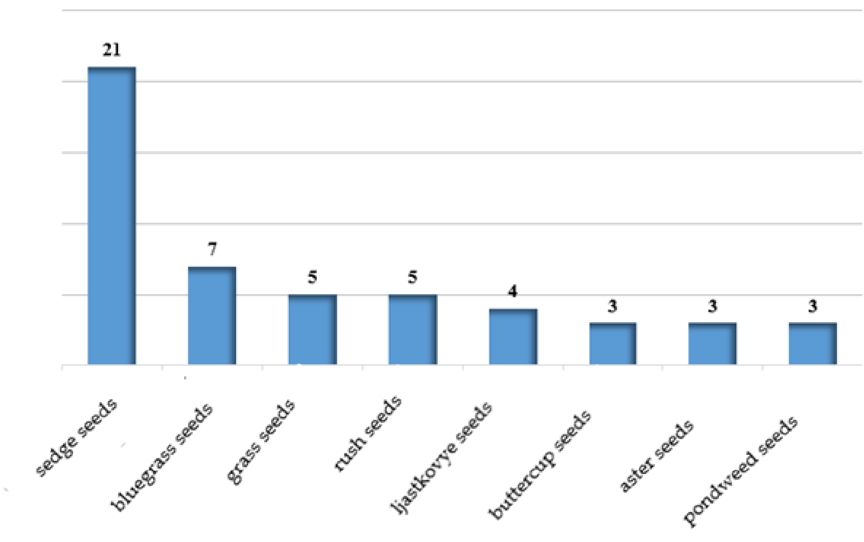

Figure 1: *The numerical ratio of aquatic plants in the Chechen Republic*

According to the classification of K. Raunkier, among 78 species there are 3 biomorphs – hemicryptophytes, cryptophytes and therophytes.

Hemicryptophytes 34 species: *Aquilegia caucasica* – Caucasian columbine , *Potentilla reptans* – Creeping cinquefoil, *Lythrum salicaria* – Willow-leaved loosestrife, *Epilobium palustre* – fireweed, *Rumex patientia* – Spinach sorrel, *Samolus valerandi* – Northern sorrel Valeranda, *Lysimachia vulgaris* – Loosestrife common, *Juncus inflexus* – Sickweed, *Schoenoptectus triquette* – Schenoplektus triangularis, *Scirpus sylvaticus* – Forest reed, *Cyperus longus* – Long-leaved sedge, *Catabrosa aquatic* - Water Adjutant, *Veronica beccabunga* - Veronica Potochnaya and others.

Cryptophytes 30 species: *Equisrtum arvense* – Horsetail, *Equisrtum fluviatile* – X Marsh wax, *Marsilea quadrifolia* – Marsilea quadrifolia, *Iris pseudacorus* – Yellow Iris, *Ranunculus repens* – Creeping Buttercup , *Butomus umbellatus* – Umbrella rush, *Rorippa austriaca* – Austrian watercress, *Berula erecta* – Berula erecta, *Polygonum amphibium* – Amphibian knotweed, *Veronica anagallus - aquatica* – Spring Speedwell, *Typha latifolia* – Broadleaf cattail, *T. angustifolia* – Narrow-leaved cattail , *Sparganium erectum* – Straight bur-reed, *Alisma plantago - aquatica* – Plantago alimentosa, *Potamogeton biliformis* – thread-leaved pondweed, *P. natans – floating pondweed* , etc.

Therophytes 14 species: *Salvinia natans* – Salvinia natans, *Trapa hyrcana* – Hyrcana Chilim, *Ranunculus sceleratus* - Poison buttercup, *Potentilla supine* – Cinquefoil low, *Polygonum amphibia* – Buckwheat (Polygonum) amphibian , *P. lapathifolium* – G. (buckwheat) sorrel-leaved, *P. persicaria* – G. (buckwheat) bird-leaved, *Bidens tripartite* – Three-part Bidens, *Polipogon monspeliensis* – Hemp-beard, *Cyperus Glaber* - Naked sedge, *Lemna minor* – Duckweed, *Cyperus glomeratus* – *Lemna trisulca* – P. trifoliate and *Juncus bufonius* – frog rush [7] .

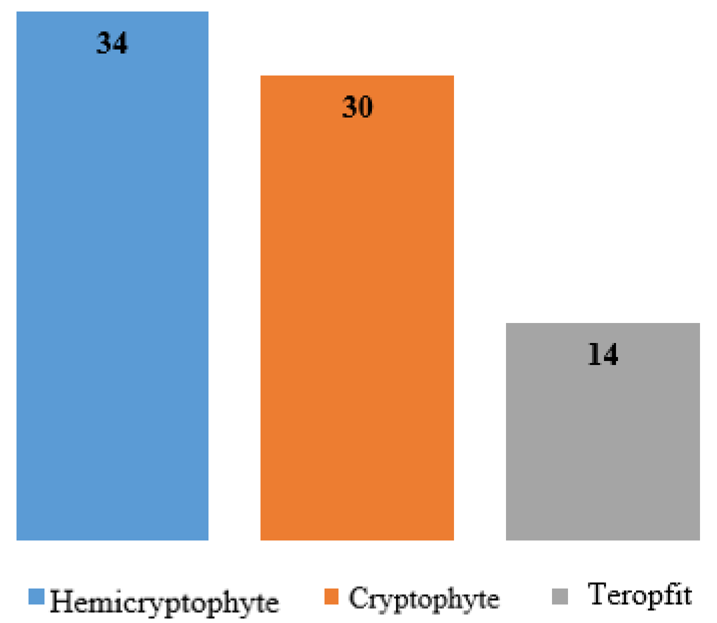

Figure 2: *Biomorphological analysis of aquatic species of the Chechen Republic*

In the process of human anthropogenic impact on nature, species that are small in number or are found scattered, rare, or very rare are at risk.

The largest number of species (32) are **scattered** , which is 41.02%: *Carex hordeistichos* Vill . – Barley-growing sedge, *Eleocharis palustris* (L.) Roem . et Schult – Marsh moth, *Schoenoptectus triqueter* (L.) Palla . – Chenoplectus triquetrum, *Scirpus sylvaticus* L. – Forest reed, *Juncellus serotinus* (Rottb .) Clarke – *Glycera notes* Chevall . (*G. Plicata* (Fries) Fries , *G. acutiuscula* H. Scholz) – Mannik plicata, *Potamogeton natans* L. – Floating pondweed, *Sparganium erectum* L. (*S. polyedrum* (Ackers , et Graebn .) Juz.; *S. ramosum* Huds .) – Straight burdock, *Sonchus palustris* L. – Marsh sow thistle, *Eupatorium cannobinum* L. – Hemp agrimony, etc.

Typically 28 species (35.89%) are found: *Ranunculus repens* L. – Creeping buttercup, *Potentilla reptans* L. – Creeping cinquefoil, *Typha angustifolia* L. – Narrow-leaved cattail, *Catabrosa aquatica* (L.) Beaur . – Water lily, *Schoenoptectus lacustris* (L.) Palla . – Lake Schenoplektus, *Bolboschoenus maritimus* (L.) Palla – Sea club-rush, *Carex riparia* Curt . – Coastal sedge, *Juncus gerardii* Loisel . – Sitnik Gerard et al.

Rarely found 17 species (21.79%): *Lemna trisulca* L. – *Carex* trifoliate*pseudocyperus* L. – False sedge, *Eleocharis uniglumis* (Link) Schult – Cyperus *glomeratus* L. – Crowded cyperus, *Polipogon monspeliensis* (L.) Desf . – *Polygonum amphibia* L. – Knotweed (buckwheat) amphibious, *Potamogeton biliformis* Pers . – Thread-leaved pondweed, etc.

Very rare 1 species is found, which makes up 1.28%: *Cladium mariscus* (L.) R. Br . – Common sword grass [7] .

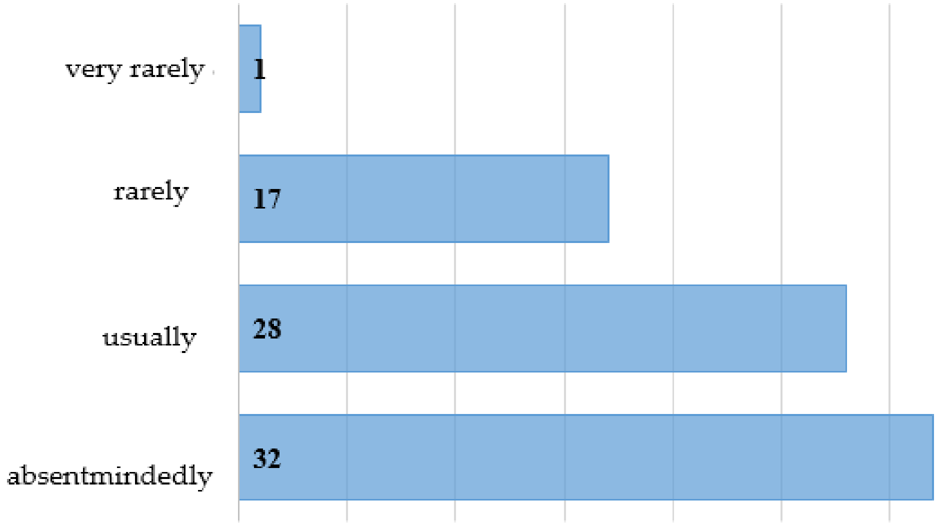

Figure 3: *Analysis of the occurrence of aquatic plant species in the Chechen Republic*

IV. Discussion

The systematic and biomorphological analysis is a scientific study focused on the flora of aquatic and riparian ecosystems in this region. The primary goal of this analysis is to examine the species diversity, taxonomic classification, biomorphological features, and ecological adaptations of aquatic plants in the specific environmental conditions of the Chechen Republic. This analysis can be broken down into several key components.

First, the **systematic analysis** involves the classification and identification of plant species present in the water bodies, such as rivers, lakes, ponds, and wetlands, as well as in adjacent shoreline areas. This process includes determining the species composition of aquatic plants, grouping them into families, genera, and species based on traditional morphological and molecular data, and analyzing their geographical distribution. It also involves comparing the local flora with that of other regions to understand regional uniqueness and shared characteristics. For example, a taxonomic breakdown may include species like Potamogeton natans (floating-leaved pondweed) from the family Potamogetonaceae, part of the class Monocotyledonae.

Second, the biomorphological analysis focuses on the morphological characteristics and life forms of aquatic plants, as well as their adaptations to the aquatic environment. This includes studying the anatomical and morphological features of the plants, such as leaf shapes, stem structures, root systems, and reproductive organs. Moreover, plants are classified according to their life forms and survival strategies in aquatic habitats, such as hydrophytes (fully submerged plants) and hygrophytes (plants growing in wet soils). These adaptations include specialized structures like aerenchyma (air-filled spaces in tissues for gas exchange), hydrophilic leaf structures optimized for water absorption, and reproductive strategies such as floating seeds or vegetative propagation. Examples include fully submerged species like *Elodea* and amphibious plants like reeds and rushes that thrive in wetland areas.

In addition to biomorphological characteristics, this analysis also examines ecological factors influencing plant growth and distribution, such as hydrological conditions (water levels, flow rates) and the impact of anthropogenic activities like agriculture, pollution, and water regulation.

Understanding these factors helps in assessing the overall health of aquatic ecosystems and the adaptability of plant species to changing environmental conditions.

The significance of this research lies in its contribution to the conservation of biodiversity. By identifying rare or endemic species and evaluating the threats to their survival, such studies play a crucial role in the development of conservation strategies. Additionally, the findings from this analysis support better management and restoration of aquatic ecosystems, particularly in the face of climate change and human impact. This type of systematic and biomorphological analysis is essential for understanding the structure, function, and preservation of aquatic plant communities in the Chechen Republic's water bodies.

Among the aquatic plants of the study area, the most numerous in terms of species content are the family *Cyperaceae* Juss . – Sedge (21 view). Family *Poaceae* Barnhart – Poaceae (7 species), *Polygonaceae* Juss . – Buckwheat and *Juncaceae* Juss . – Rush (5 species), 4 species belong to the *Laimiaceae family* Until . – Lamiaceae, the families Ranunculaceae, Asteraceae and Podestaceae have 3 species each, 7 families have 2 species, 13 families contain only 1 species each.

According to the classification of K. Raunkier, among 78 species there are 3 biomorphs. There are 34 species of hemicryptophytes, 30 species of cryptophytes, and 14 species of therophytes.

According to the occurrence analysis, 32 species are scattered, 28 are commonly found, 17 are rare, and 1 species is very rare.

The results of this study show that aquatic plants of the republic contribute to the richness of plant diversity, indicating the need for conservation and protection of the study area.

INNOVATIVE TECHNOLOGIES AND ARTIFICIAL INTELLIGENCE IN REPRODUCTIVE MEDICINE

Marziyat Sarbasheva, Islam Eleskhanov Magomed-Salah Deshiev,
Deniel Bekhoev, Hasan Yandiev
•
Medical Academy named after Kh.M. Berbekov, RUSSIA

Abstract

Innovative technologies in reproductive medicine are radically changing approaches to the treatment of infertility, genetic diseases and reproductive health problems. Modern methods such as assisted reproductive technologies (ART), including in vitro fertilization (IVF) and embryo cryopreservation, have significantly increased the chances of successful conception. Key achievements have also included preimplantation genetic testing (PGT), which allows identifying genetic abnormalities in embryos before they are transferred to the uterus, and genome editing technologies (such as CRISPR), which offer the prospect of correcting genetic defects at an early stage of development. In addition, stem cell research is actively developing, which in the future may make it possible to create artificial gametes, which will be a solution for people who lack functional germ cells. Another significant breakthrough is uterine transplantation, which gives a chance to bear a child to women who do not have their own functional uterus. These advances not only increase the success of reproductive procedures, but also open up new horizons in the field of personalized medicine and raise important ethical questions related to reproductive technologies. Innovative developments in reproductive medicine are aimed at improving the quality of life of people and expanding opportunities to overcome barriers to parenthood, making them an important component of modern healthcare.

Keywords: innovative technologies, reproductive medicine, ART, IVF, cryopreservation, preimplantation genetic testing

I. Introduction

Innovative technologies in reproductive medicine are revolutionizing the way we approach fertility, genetic disorders, and overall reproductive health. Over the past few decades, significant advancements have emerged, offering new hope to individuals and couples struggling with infertility and hereditary diseases. These developments are particularly evident in the realm of assisted reproductive technologies (ART), such as in vitro fertilization (IVF), which has dramatically improved success rates for conception. The ability to freeze embryos and eggs through cryopreservation has further expanded reproductive options, allowing patients to preserve their fertility for future use.

In parallel, preimplantation genetic testing (PGT) now enables the screening of embryos for genetic abnormalities before implantation, reducing the risk of passing on hereditary diseases and improving the overall chances of a healthy pregnancy. Additionally, cutting-edge gene-editing technologies like CRISPR are opening new doors by offering the potential to correct genetic defects at the embryonic stage, presenting possibilities for eliminating certain inherited disorders altogether.

Research into stem cell therapy and the potential to develop artificial gametes (sperm and eggs) is another exciting frontier, especially for individuals who cannot produce viable reproductive cells. This could provide a breakthrough for those previously considered untreatable by conventional methods. Furthermore, the development of uterine transplantation offers women who lack a functional uterus the opportunity to carry a pregnancy to term, which was previously impossible.

These innovative technologies are not only enhancing the clinical success of fertility treatments but are also driving a deeper understanding of human reproduction at the molecular and genetic levels. This progress is facilitating the rise of personalized reproductive medicine, where treatments can be tailored to an individual's specific genetic and biological profile.

As the field of reproductive medicine evolves, it brings with it significant ethical, legal, and social implications. Questions around the use of genetic editing, embryo selection, and reproductive autonomy raise complex debates about the future of human reproduction. At the same time, the promise of these technologies offers the potential to overcome previously insurmountable barriers to parenthood, fundamentally transforming the landscape of reproductive health.

In light of these rapid advancements, reproductive medicine is entering a new era, where science and technology intersect to provide more effective, individualized solutions for a growing number of people around the world.

II. Methods

The study and application of innovative technologies in reproductive medicine involve a multidisciplinary approach, incorporating advanced scientific techniques, medical procedures, and cutting-edge research. Key methods used in the field include:

-In Vitro Fertilization (IVF):

This method involves retrieving eggs from the ovaries and fertilizing them with sperm in a laboratory setting. After successful fertilization, the embryos are cultured and then transferred to the uterus for implantation. IVF is one of the most common assisted reproductive technologies used to treat a variety of infertility issues.

-Preimplantation Genetic Testing (PGT):

PGT is a technique used to screen embryos for genetic abnormalities before implantation during IVF cycles. There are different forms of PGT, such as PGT-A for detecting aneuploidy (chromosomal abnormalities) and PGT-M for identifying specific monogenic genetic disorders. This method increases the chances of a healthy pregnancy by selecting genetically viable embryos.

-Uterine Transplantation:

Uterine transplantation involves transplanting a healthy uterus into a woman who does not have a functional uterus, often due to congenital conditions or previous surgery. After the transplant, IVF is typically used to implant embryos into the uterus, allowing the woman to carry and deliver a child. This method is particularly groundbreaking for individuals who otherwise could not achieve pregnancy.

III. Results

Artificial intelligence (AI) is gradually being incorporated into various fields of medicine, including reproductive medicine. In this domain, AI can enhance the selection and prediction of sperm cells, eggs (oocytes), and embryos, as well as improve predictive models for in vitro fertilization (IVF). The use of AI in reproductive medicine is driven by the emotional and psychological toll experienced by individuals or couples who are unable to conceive. However, the application of AI in this field remains in the early experimental stages, raising complex ethical and normative issues. Ethical concerns arise due to the lack of robust evidence supporting the effectiveness of certain AI systems, as well as challenges in obtaining fully informed consent from affected individuals.

Additional ethical considerations include the potential risks to future offspring and the difficulty of ensuring that patients receive adequate information about the AI-driven processes. The ability to fulfill the desire for children has a significant impact on patient well-being and reproductive autonomy. More accurate predictions and the possibility of freeing up physicians to spend more time with their patients are positive outcomes. However, it is essential that clinicians handle patient data responsibly. Since multiple actors are involved in diagnosis and treatment decisions when AI is used, accountability becomes a concern, particularly in the case of errors.

Fairness issues also emerge regarding resource distribution and reimbursement for AI-based treatments. Therefore, before integrating AI into clinical practice, it is critical to thoroughly evaluate the quality and scope of the data being used and address transparency concerns. In the medium and long term, it is necessary to consider the potential negative impacts and societal changes that may arise from the widespread use of AI in reproductive medicine.

IV. Discussion

Artificial intelligence (AI) is advancing rapidly, with applications being integrated across various sectors, including several fields of medicine. Complex AI algorithms are capable of analyzing vast amounts of data to enhance diagnoses, prognoses, and preventive measures. In recent years, the analysis of image data has emerged as a promising application area, with some studies suggesting that AI-generated results may surpass those of human experts. Additionally, AI is expected to streamline workflow processes in hospitals and improve patient monitoring.

In reproductive medicine, new applications of AI methods are being explored. Individuals or couples desiring children but facing infertility often experience significant life crises and a diminished quality of life. The inability to conceive can be seen as a barrier to fulfilling the widely accepted need for reproduction and child-rearing, leading to psycho-existential concerns as it threatens individuals’ visions for their future. The birth of Louise Brown over 40 years ago marked a pivotal moment, ushering in a new era of hope for infertile individuals and couples by making in vitro fertilization (IVF) a viable option. Estimates suggest that infertility affects up to 186 million people globally.

The ongoing advancement of reproductive technologies—such as oocyte and embryo cryopreservation, IVF, preimplantation genetic diagnostics (PGD), and the ability to select preimplantation embryos based on morphokinetic criteria—has significantly improved clinical pregnancy rates over the past four decades.

However, several challenges remain. In Germany, the average likelihood of achieving a live birth after a fresh embryo transfer through IVF or intracytoplasmic sperm injection (ICSI) is approximately 24%, while the probability for previously cryopreserved embryos is about 20%. Essentially, despite successful fertilization and cell division, only one in four fresh embryo transfers and one in five cryo-transfers will result in a live birth. The age of the woman’s oocytes and the quality of the embryos are critical factors influencing the success of IVF treatments. Unfortunately, reliable methods for accurately assessing the quality of oocytes, sperm, and embryos are still lacking. Although preimplantation diagnostics can be employed before embryo transfer, this approach is ethically contentious. In Germany, it is only permitted under specific conditions, is technically complex, costly, and carries risks of injury or destruction to the embryo.

The impetus for developing AI technologies in reproductive medicine lies in the goal of enhancing treatment outcomes and prognoses for infertile patients by synthesizing large datasets to derive meaningful insights. This context shapes our ethical discussion, which considers both the needs of individuals with unfulfilled parental desires and the application of specific AI technologies to achieve medical objectives. The principles of healing, helping, and alleviating—

aligned with the overarching principle of beneficence—provide the ethical framework for this dialogue. Practices such as extracorporeal fertilization and selective reproduction (e.g., following PGD) remain contentious, and research alongside the potential implementation of AI in clinical settings introduces complex normative questions regarding both content and procedures. Therefore, a proactive ethical debate is essential, even as AI research and its application in reproductive medicine are still in their infancy.

In light of this, we will begin with a brief overview of the current state of research and development in this field, followed by a structured ethical analysis of the potential uses of AI methods in reproductive medicine. We will then explore the impact of these technologies on the physician-patient relationship. Finally, we will consider possible future developments in AI-driven reproductive medicine and briefly address the associated social challenges.

In recent decades, advancements in reproductive medicine, such as preimplantation genetic diagnosis (PGD) and intracytoplasmic sperm injection (ICSI), have frequently transitioned from laboratory settings to clinical applications without undergoing thorough evaluations of their effectiveness and safety. Research involving human subjects in reproductive medicine is particularly sensitive from an ethical standpoint and presents unique challenges. Initially, the intended mother is the primary subject affected by the study, shouldering most of the physical and psychological burdens. However, the research and expected innovations in assisted reproduction, including AI applications, can result in the birth of offspring who are also impacted by the potential risks of these experiments, even though they cannot consent to participate. Additionally, the long-term effects on these offspring, resulting from experimental procedures in assisted reproduction, may not be fully understood for years. This situation is complicated by ethical questions surrounding the testing of new procedures involving human embryos.

In all future research concerning the use of AI in reproductive medicine, it will be crucial to provide well-considered information to intended mothers or parents. It's essential to recognize the unfavorable scenarios that can arise when conveying information to potential parents; participants in studies might develop false hopes or unrealistic expectations, especially when innovative, attention-grabbing technologies are being tested. This is particularly relevant for women or couples who have endured long-standing difficulties with childlessness, as they represent a vulnerable group. Individuals participating in such studies may feel they are facing their "last chance" to realize their parental aspirations, necessitating special precautions to ensure that participation is truly voluntary.

Patients' Well-Being and Autonomy

One of the primary objectives of incorporating AI systems into predictive models for IVF is to enhance outcomes compared to traditional reproductive medicine techniques. A key indicator of such improvements would be an increased baby-take-home rate, which reflects a higher likelihood that assisted fertilization will result in a live birth. This enhancement could alleviate both the psychological and physical suffering of patients. The normative principle of prioritizing patient welfare in assisted reproductive medicine involves delivering the most suitable treatment based on objectively measurable medical criteria and considering the patient's subjective experience, preferences, and satisfaction with the treatment. The future integration of AI technology could potentially benefit both aspects.

An analysis of 122,560 treatment cycles in Germany revealed that 45,699 patients discontinued therapy after having a child, while 76,861 (62.7%) stopped before achieving their desire to conceive. Various factors contributed to therapy discontinuation, such as a lack of transferable embryos due to immature oocytes, unsuccessful oocyte retrieval, failed fertilization attempts, and halted embryo development. These challenges can dissuade patients from continuing treatment. Other reasons for discontinuation included inadequate response to stimulation, overstimulation syndrome, premature ovulation, and incorrect hormone administration, which could lead to unsuccessful treatment outcomes. The emotional toll of not conceiving despite multiple reproductive medical interventions is believed to contribute significantly to therapy discontinuation. Studies have also highlighted relationship difficulties and other personal issues alongside the physical and psychological burdens of infertility treatment. Furthermore, societal stigmas related to infertility—such as shame and social exclusion—often exacerbate patients' experiences.

Enhanced and expedited treatment options, potentially offered through future AI applications, could help some couples mitigate these stresses, thereby contributing positively to their overall well-being.

Reproductive Autonomy

The use of AI in reproductive medicine can also be evaluated in terms of patients' reproductive autonomy. Reproductive autonomy is a normative concept defined as individuals' capacity to make informed, uncoerced decisions about their own reproductive choices. From this perspective, measures that empower patients to exercise their reproductive freedom, such as AI applications in reproductive medicine, should ideally be accessible to all individuals seeking to conceive. Conversely, restrictions on reproductive autonomy should only be permissible if new technologies in reproductive medicine demonstrably harm patients or their potential offspring. This autonomy can be viewed as an entitlement, as the ability to exercise control over reproduction is fundamental to personal identity. Therefore, efforts should be made to assist couples in achieving their parenting aspirations, which includes ensuring equitable access to emerging reproductive technologies, including AI applications. However, it is vital to avoid the risks associated with inadequate information, as highlighted earlier, to allow patients to fully exercise their reproductive autonomy in this experimental field.

Benefits and Challenges for the Physician–Patient Relationship

The potential integration of AI into reproductive medicine will undoubtedly influence a cornerstone of medical practice: the physician-patient relationship. AI may necessitate a re-evaluation of the reproductive specialist's professional role, as they will serve as the intermediary between algorithmic outputs and treatment decisions. Physicians will need to address not only the biological factors contributing to infertility but also the psychosocial and emotional stresses patients face during treatment. The future utilization of AI could provide significant benefits, enabling better predictions of individual patients' likelihood of becoming pregnant. Existing data can inform these probability assessments, such as using the woman's age. A more precise prognosis could empower physicians to deliver better-informed recommendations and therapies, ultimately enhancing treatment efficiency by optimizing the selection of sperm, oocytes, and embryos. Even minimal contributions from potential AI applications could provide valuable support amid the stresses associated with infertility treatment. Additionally, it is anticipated that automated support systems in medicine will free up physicians to devote more time to building stronger relationships with their patients.

Abstract

The article presents an approach to assessing risk management to ensure sustainable development of territories and businesses using artificial intelligence and gaming technologies for continuing professional education. Features of risk assessment related to ensuring effective development of territories and businesses are shown, in conditions of impossibility to apply statistical methods to determine the probability of occurrence of dangerous events and low degree of formalization of description of severity of their consequences.

The choice of a two-factor risk management model based on an expert approach to determining the likelihood of hazardous events and the severity of their consequences is justified. The problems of gaining expert knowledge are formulated and a method for solving them using innovative open-type games that have proven themselves in continuing professional education of managers in the process of solving complex semi-structured problems is proposed.

An approach to structuring expert knowledge in artificial intelligence systems is proposed. The structure of the project for the formation of knowledge bases for the analysis of spatial development risks has been formed.

Keywords: risk analysis, development of territories and business, innovative games, gaining expert knowledge, continuing professional education, artificial intelligence systems

I. Introduction

The most important component of the climate agenda in recent years is the management of climate risks with a shift in focus from mitigation to adaptation to climate change in the constituent entities of the Russian Federation and production systems.

These issues were discussed at the strategic session “Climate risks” at the beginning of 2024. Regional Context” in early 2024, where the ESG Alliance and Kept presented the methodology and guidelines for assessing risks associated with climate change. The innovation of the proposed methodology is that it is based on the PDCA management cycle, on which all international management standards are based, and a process approach is used to assess risks, allowing to identify the impact of climate change on each production process and the entire production system as a whole. The transition from risk identification and assessment to risk management, including strategic goal-setting, planning and continuous monitoring of the effectiveness of response measures within the framework of the chosen strategy, followed by work to improve activities at all system levels, is a key point in the methodological transition from plans for the social and economic development of the territory to their practical implementation at the business level (Figure 1).

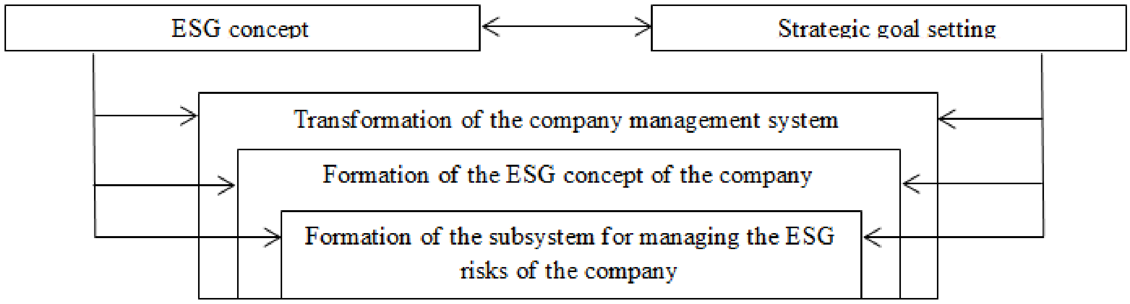

Figure 1: *Formation of the company's risk management subsystem within the framework of the sustainable development concept*

Risk management based on ESG principles with a focus on taking into account environmental, social and governance aspects in the activities of companies and assessing their sustainability and impact on the environment, society and internal governance structure [1] is part of the approach to sustainable development and the basis for the practical implementation of the climate risk management methodology. The ESG principles built into the company's management system, focusing on specific aspects of activities and investments, link the corporate strategy with the strategy of social and economic development of the territory.

According to the assessment of the professional community, the strategies for the social and economic development of the constituent entities of the Russian Federation and the action plans for their implementation, which should ensure "reducing the vulnerability of the country's national security system, economic entities and citizens due to changes in the global climate, the climate on the territory of the Russian Federation, the territories of neighboring states, in the adjacent waters of the World Ocean, as well as the use of favorable opportunities caused by these changes" [2], by the beginning of 2024 determined the system of operational and long-term measures to adapt territories to climate risks to no more than a "weak C" [3].

By order No. 397 dd. June 28, 2024, the Ministry of Economic Development of Russia adjusted the Methodological Recommendations for the Development and Adjustment of the Strategy for the Social and economic Development of a Subject of the Russian Federation and the Action Plan for its Implementation, previously approved by order No. 132 dd. March 23, 2017, supplementing them with an emphasis on adaptation. The adjustments also affected the orders of the Ministry of Economic Development of Russia No. 267 dd. May 13, 2021 "On approval of methodological recommendations and indicators on adaptation to climate change" and No. 927 dd. December 28, 2023 "On approval of Methodological recommendations for assessing possible damage from the impact of climate risks, including recommendations for the formation of a list of climate-vulnerable objects in economic sectors, in the constituent entities of the Russian Federation and Methodological recommendations for monitoring and assessing the effectiveness and efficiency of measures to adapt to climate change."

However, despite the ESG Alliance's in-depth study of enterprise risk management issues related to climate change and the regulator's active position regarding the systemic consideration of climate and economic risks in the territories, the issue of developing tools for the practical application and replication of the proposed methods is acute.

II. Methods

The development of strategies for the social and economic development of the constituent entities of the Russian Federation and action plans for their implementation should be based on an analysis of data across all major climatic parameters and threats.

The Methodological Recommendations for the Development and Adjustment of the Strategy for the Socioeconomic Development of a Subject of the Russian Federation and the Action Plan for its Implementation propose using the results of scientific research, including publications from the Climate Center and official reports from Roshydromet, to forecast the dynamics of climate risks. It is assumed that "within the framework of the target scenario of long-term development, the main macroeconomic parameters of the development of a constituent entity of the Russian Federation, indicators of its social, sectoral and territorial (spatial) development for the long term can be determined, priority areas can be identified, including the development of human capital and social sphere, key sectoral complexes and types of infrastructure, scientific and innovative sphere and institutional environment, rational use of natural resources and ensuring environmental safety, adaptation to climate change, foreign economic and interregional cooperation, as well as territorial (spatial) development of a constituent entity of the Russian Federation" [4].

The assemblies of global climate models recommended by the regulator for calculating indicators of future climate change in the territory of the subjects of the Russian Federation and the family of scenarios of anthropogenic impact, the evolution of society and ecosystems, taking into account the goals and objectives of the long-term development of the subject, the internal conditions of its development, cause difficulties in practical use and require the involvement of specialists with competencies and experience in the field of climate modeling.

The regional strategies and company reports we studied generally do not use forecasting, but rely only on historical information contained in Roshydromet databases.

Since the use of statistical methods in the analysis of the effective development of territories and businesses is limited by the lack of representative samples, expert knowledge is also required to determine climate risks, firstly, when forming scales for assessing the probability of threats and the severity of their consequences, and secondly, when establishing the levels of the risk ranking matrix.

Building expert knowledge bases is hampered by the narrow specialization of experts and the high degree of individualization of their knowledge. Technically, the system integration of existing disparate knowledge is possible on specially created platforms. However, the problem of gaining expert knowledge has not yet been solved unless it is reflected in printed texts or electronic databases. There are two main difficulties in gaining expertise from specialists in relevant fields

- the reluctance to give unique knowledge to public databases due to the risk of reducing personal demand;
- the inability of an expert in some cases to build sound relationships between elements due to the "compiled" nature of the knowledge.

And if the first difficulty can be removed by motivational mechanisms, in the second case the problem is directly dependent on the complexity and uniqueness of knowledge about the vulnerabilities, risks and opportunities for spatial development (territory and related business) in the future. To solve the problem of building an expert knowledge base, innovative games (IG) can be used, which have proven themselves well in continuing professional education of managers in the process of solving complex, weakly structured problems.

The practice of using innovative games (innovative seminars) in continuing professional education (CPE) of managers and specialists allowed formulating the concept of innovative-project training of personnel (IPT), based on the following principles.

1. *Learning through activity:* the effectiveness of the learning process is significantly higher if its participants are engaged in solving their own problems during the learning process, and knowledge is given for a specific problem (the principle of "action-knowledge-action").
2. *Project-based organization of training:* training is a component of a real project and is aimed at supporting the process of its implementation; the result of training, along with new competencies, is the completion of a project task by a group (subgroups) (the "here and now" principle).

3. *The principle of representation sampling:* in practice, to implement a specific project, a team is formed in such a way that the solution to the problem is provided by a combination of all the necessary competencies. Accordingly, in the case of project-based organization of training, both for diagnostic tasks (analytical sessions) and for project work (project-innovation sessions), the group of seminar participants should be sufficient to collectively represent a "living" functional model of the type of activity that the project is aimed at.
4. *Immersion principle:* the training consists of a set of completed modules lasting from 1 to 3 days, during which group members are completely separated from their current work and immersed in the process of solving a specific problem within the project.
5. *Multitasking of training:* along with substantive issues, the training process addresses the issues of building effective interaction between team members (regardless of their status, age and experience), the issues of personal self-determination in relation to new ideas and solutions, and the development of new individual management tools.

Unlike business, role-playing, and simulation games, IG does not imply a known, pre-determined substantive result. This is a technology for organizing the process of solving complex semi-structured problems based on group dynamics. Here, teachers act primarily as consultants on the effective organization of collective work on the tasks set to the group, and only secondarily as the holders of substantive knowledge, which is given in very measured doses when a corresponding request arises [5].

The multitasking of the IN involves work in three planes, for each its own type of result is formed (Fig. 2):

- a meaningful solution to the task set, which can be a formed structure of knowledge about risks in a certain area, the main provisions of the development strategy of the region or company in the conditions of identified climatic risks, a process model of the activities for the implementation of the strategy, taking into account risks of appropriate levels, and more, depending on the projects being worked out;
- solving the problems of team interaction through building effective communications based on a process approach, regulations, and protocols;
- solving problems of personal ability by developing new personal tools and methods of working with a particular problem based on personal self-determination in relation to it and to the team of partners involved in this work.

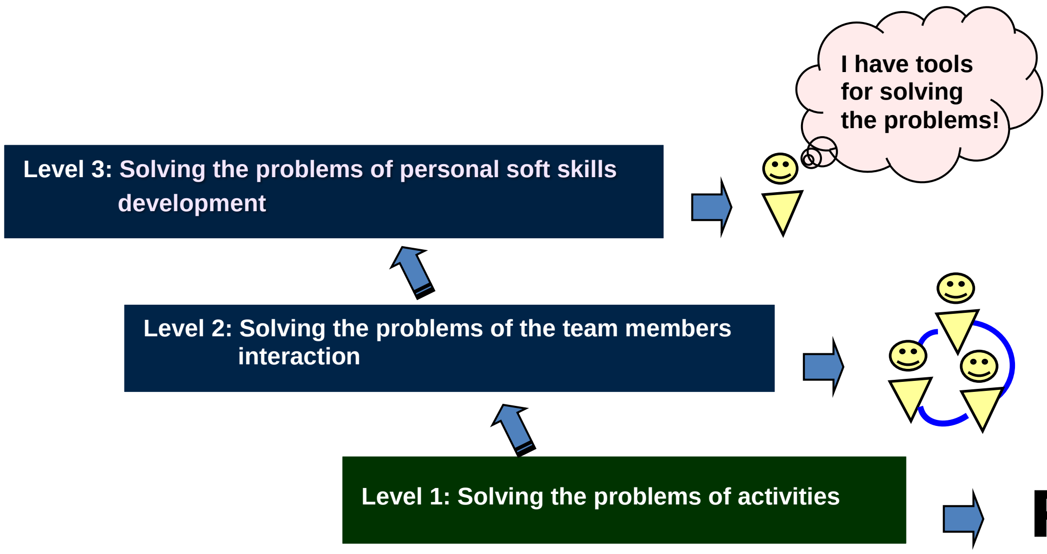

Figure 2: *Three types of outcomes of the Innovative Workshop*

Each plane uses its own methods and tools. Logical and technical tools in the substantive area, social and technical tools in the communicative area, and psychotechnical tools in the personal area.

A participant in the educational process gains an increase in knowledge on a given issue not only through communication with teachers, but also through intensive exchange of information in working groups. And unlike traditional forms of training, two additional results appear here (which are most valuable for working with experts) - these are the skills of organizational social and psychological management of a team of specialists with specialized knowledge, building effective communications with them, as well as new personal tools and methods for diagnosing unstructured problem areas.

III. Results

The organization of the process of gaining expert knowledge in the course of continuing professional education of the holders of this knowledge, built on the basis of the IPT concept, includes the following main stages.

1. *Selecting a topic* for improving the qualifications of holders of expert knowledge that would not only interest them, but would also involve their active involvement in diagnosing the problem and developing ideas for solutions in relation to the development of the chosen area. For example, having chosen the topic of developing a regional development strategy for IG, experts, working as part of a group of stakeholders, will participate in the analysis of the impact of the external environment on the sustainability of the regional economy, discuss the risks of adapting business and the region to climate change, generate scenario forecasts of the impact of risks on the sustainability of regional development and enterprise strategies, etc.
2. *Formation of the session structure of the IG* based on the decomposition of the topic into a sequence of tasks and planned results, group work on which will create conditions for the gaining of expert knowledge for the formation of databases in the relevant areas.
3. *Determination of the participants* based on the principle of representation sampling. Along with experts, the group shall include the representatives of government bodies responsible for this area, business leaders, systems analysts and other interested categories. In this work, systems analysts or knowledge engineers have a special function, which is to systematize all the information discussed based on the structure of the knowledge base.
4. *Process planning:* selection of methods and tools and development of the temporary structure of the seminar (timing).
5. *Preparing a team of moderators and systems analysts:* defining their functions in the work of the seminar, analyzing the expected results and discussing the necessary and sufficient conditions for obtaining them. Selection of necessary materials. Elaboration of technical requirements for extractable knowledge.

The IG organizational structure includes:

- presentation by the moderator setting a common task, a brief introduction to the content of each session and setting the tasks of individual sessions,
- information insertion of the leader and experts on emerging requests,
- subgroup work on the objectives for each session
- common discussions on the results of the work of the groups at each session with an expert analysis of the content,
- systematization of the results of discussions for each session by leaders and experts,
- reflective work of the seminar participants.

It is very important for the success of the work to correctly decompose the general topic into local tasks for discussion, to form the composition of focus groups according to the principle of equivalence and to ensure group dynamics both when working in focus groups and during the discussion. The total scope of work between focus groups is distributed in such a way that the results are combined in a complementary manner. For example, groups can conduct an analysis of threats and their consequences by types of climate adaptation at the regional level or by industry specifics, expertly determining the likelihood of their occurrence and the severity of possible consequences. And it is preferable to coordinate scales for assessing the probability and severity of consequences during a general discussion - this will allow identifying a larger number of expert opinions and thereby increasing the reliability of the assessments.

The part of the work that is more effectively carried out on an individual basis, such as a financial assessment of the severity of consequences or justification of the cost of risk management strategy activities, is best transferred to the stage of individual revision of projects with reference to specific conditions.

The principle of forming focus groups at the stage of project work is based on the commonality of substantive tasks. Group dynamics are achieved through the correlation of common parts of the content and the building of connections between individual tasks during discussion.

Integrated use of IG together with information modules and consulting within the continuing professional education programs of managers and specialists, being steps of a real consulting and educational project, at the output of which developed forecasts, strategies, designed risk management systems or any strategic changes in the organization/entity formed the basis of innovation and project technology. The need to structure climate risks in conditions of high uncertainty, to develop costly measures to respond to them, including regulatory ones, and sometimes to revise the development strategy of a territory or organizations located there increases the responsibility for adequately adjusting the innovative project technology to solve the problems of gaining expert knowledge.

IV. Discussion

Strategic management of territorial development risks is inextricably linked with the business strategies of companies operating on the territory, which shall also identify and assess their risks, build strategies for responding to them and analyze the effectiveness of specific reactions with the subsequent improvement of the entire management cycle. The key point in the risk management system is a clear delineation of responsibilities in the risk management system, the development of a risk culture in the company and communicating to employees the importance of risk management in the organization. The considered innovative project technology in general and specific IG in particular in climate risk management can serve not only as a tool for gaining expert knowledge, but also facilitate the creation of risk coordinators within the community with the involvement of external experts in the field of risk management.

Climate risk management tasks are increasingly being considered as a subject of artificial intelligence systems, where rules and ontologies are powerful tools for structuring expert knowledge. The choice between them depends on the specific task and the available data and constraints. Structuring expert knowledge in artificial intelligence systems is a challenging task that requires a balance between accuracy, interpretability, and efficiency. The application of the proposed process for gaining expert knowledge contributes to the development of hybrid approaches to the design of artificial intelligence systems that combine the advantages of structured and unstructured methods.

Abstract

Innovative educational technologies have emerged as essential drivers in the development of human capital, significantly enhancing the educational landscape by equipping individuals with the necessary skills and knowledge to thrive in today's rapidly changing economic environment. These technologies encompass a wide array of tools, such as e-learning platforms, artificial intelligence (AI)-based learning systems, virtual and augmented reality applications, and personalized educational approaches. By integrating digital methods into traditional educational frameworks, these innovations foster a more interactive, engaging, and effective learning experience. The implementation of innovative educational technologies not only enhances access to quality education but also promotes lifelong learning, critical thinking, and problem-solving abilities, which are vital in today's workforce. For instance, e-learning platforms offer flexibility and accessibility, allowing learners to acquire skills at their own pace, while AI-driven personalized learning systems adapt to individual learning styles and needs, enhancing overall educational outcomes. Moreover, the incorporation of collaborative tools and gamification strategies within these technologies encourages teamwork and creativity, further preparing individuals to navigate the complexities of the modern labor market. This is especially important in fostering an entrepreneurial mindset and innovative thinking, which are crucial for driving economic growth and sustainability. As educational institutions increasingly adopt these innovative technologies, they play a pivotal role in transforming educational curricula, aligning them with industry demands, and preparing students for future challenges. Consequently, the development of human capital through innovative educational technologies is not merely an enhancement of educational practices but a foundational element for achieving sustainable economic growth and ensuring competitiveness in a globalized economy.

Keywords: innovative educational technologies, human capital development, e-learning, artificial intelligence, personalized education, digital tools, workforce skills, sustainable growth

I. Introduction

In an era marked by rapid technological advancements and globalization, the importance of developing human capital has become increasingly evident. Human capital refers to the skills, knowledge, and competencies possessed by individuals that enhance their productivity and ability to contribute to the economy. As industries evolve and labor markets become more competitive, equipping individuals with the necessary tools for success is essential. Innovative educational technologies have emerged as pivotal instruments in this endeavor, transforming traditional educational paradigms and providing new avenues for learning and skill acquisition.

Innovative educational technologies encompass a broad spectrum of digital tools and platforms, including e-learning systems, online resources, virtual reality (VR), artificial intelligence (AI), and gamification techniques. These technologies not only enhance the delivery of educational content but also facilitate personalized learning experiences that cater to the diverse needs of learners. By integrating these innovative approaches into educational curricula, institutions can significantly improve the quality of education, making it more relevant and aligned with the demands of the modern workforce.

The shift towards innovative educational technologies is driven by several factors. First, the growing need for a skilled workforce capable of adapting to the fast-paced changes in various industries necessitates an educational framework that fosters critical thinking, creativity, and problem-solving skills. Second, the rise of online and blended learning environments allows for greater accessibility, enabling individuals from diverse backgrounds to engage in lifelong learning and professional development. Finally, the integration of technology into education aligns with the principles of personalized learning, empowering students to take control of their educational journeys.

This introduction sets the stage for an in-depth exploration of how innovative educational technologies can foster human capital development. By examining their applications, benefits, and potential challenges, we aim to provide a comprehensive understanding of the transformative role these technologies play in shaping a skilled and adaptable workforce. Ultimately, harnessing the power of innovative educational technologies is not just about enhancing educational outcomes; it is about creating a sustainable future where individuals are equipped to thrive in an ever-changing global economy. For several decades, economic growth has emerged as a prominent topic of discussion within the field of economics, garnering significant attention from numerous economists. The long-standing disparities in the performance of various territorial units and the living standards of their populations are evident both among countries and within their administrative divisions. To maintain a successful economy, it is essential to continuously enhance and focus on key areas that ensure sustainability and bolster the country's competitive standing.

Although the magnitude of these disparities fluctuates and, according to statistics (OECD, 2020), has been decreasing over time, economists continue to investigate the underlying causes of these inequalities. The rationale is straightforward: regions with lower rates of economic growth tend to have prolonged lag periods, which diminishes their capacity for independent development. This situation places added pressure on state institutions to fulfill social responsibilities, particularly concerning the allocation of public resources that are intended to supplement or even replace the development of internal resources. Consequently, many theorists and practitioners in economics seek to identify the driving forces behind regional growth.

II. Methods

The examination of innovative educational technologies as a means for fostering human capital development involves a multifaceted approach. The research employs both qualitative and quantitative methods to provide a comprehensive analysis of the effectiveness, implementation, and impact of these technologies in educational settings. Below is a detailed outline of the methods used in this study:

1. Literature Review

A thorough review of existing literature on innovative educational technologies and human capital development forms the foundational framework for this study. Key sources include academic journals, industry reports, and case studies that explore the intersection of technology and education. This review aims to identify best practices, theoretical frameworks, and empirical evidence supporting the integration of innovative educational technologies into learning environments.

2. Data Collection

- Surveys and Questionnaires: Surveys will be distributed to educators, students, and educational administrators to gather data on their experiences with innovative educational technologies. The surveys will assess perceptions of effectiveness, accessibility, and the impact on learning outcomes. Key areas of focus include:

- Frequency of technology use in the classroom
- Types of technologies implemented (e.g., e-learning platforms, VR, AI)
- Perceived benefits and challenges of using these technologies
- Impact on student engagement and motivation

- Interviews: Semi-structured interviews will be conducted with a select group of educators and technology integration specialists. These interviews will provide deeper insights into the strategies employed for technology integration, the challenges faced during implementation, and success stories related to human capital development.
- Case Studies: Detailed case studies of educational institutions that have successfully integrated innovative educational technologies will be conducted. These case studies will highlight specific programs, teaching methodologies, and outcomes achieved through the use of technology.

3. Data Analysis

- Quantitative Analysis: Statistical methods will be employed to analyze survey data. This includes descriptive statistics to summarize participant demographics and responses, as well as inferential statistics to identify correlations between the use of educational technologies and improvements in learning outcomes.
- Qualitative Analysis: Thematic analysis will be conducted on interview transcripts and open-ended survey responses. This analysis will identify recurring themes, patterns, and insights related to the experiences and perceptions of educators and students regarding innovative educational technologies.

4. Comparative Analysis

To contextualize the findings, a comparative analysis of institutions that have adopted innovative educational technologies versus those that have not will be conducted. This will involve examining differences in educational outcomes, student satisfaction, and overall effectiveness in fostering human capital development.

5. Evaluation Framework

An evaluation framework will be developed to assess the impact of innovative educational technologies on human capital development. This framework will include key performance indicators (KPIs) such as:

- Improvement in student retention and graduation rates
- Enhancement of critical thinking and problem-solving skills
- Increases in student engagement and participation
- Positive feedback from students regarding the learning experience

6. Synthesis of Findings

The study will synthesize the findings from the literature review, data collection, and analysis to provide a comprehensive understanding of the role of innovative educational technologies in fostering human capital development. The results will be presented in a structured format, including visual representations (charts, graphs) to illustrate key trends and outcomes.

III. Results

Digitalization is significantly lowering the production costs associated with goods and services while also minimizing local and cross-border trade expenses. The Internet of Things (IoT) and e-commerce are central to this transformation, shifting traditional trading systems toward modern business frameworks within the global economy.

Big data, alongside its analysis by humans and artificial intelligence, is further reducing communication costs. Individuals and nations can engage in communication at minimal expenses, enhancing the marketability of products both domestically and internationally. Companies leverage big data analysis to cut production costs and foster the innovation of competitive goods. Such innovations can bolster a country's productivity and pave the way for technological advancements. This technological progress serves as a vital instrument for fostering global cooperation in technology.

The interplay between big data analysis, informed production decision-making, innovation of competitively priced products, increased domestic productivity, and readiness for global technological collaboration can drive sustainable digital transformation worldwide.

The emergence of big data and artificial intelligence is reshaping traditional business models, benefiting both consumers and traders alike. Unlike conventional database management systems, big data encompasses vast amounts of varied information, including numerical data, text, audio, and video. Advanced analytical tools make it easy to process and derive insights from this wealth of information.

Artificial intelligence enhances the analysis of big data and can autonomously make decisions based on the insights gathered. This interaction between computers and AI algorithms allows retailers to gain deeper insights into consumer behavior, while suppliers can better understand retailers' demands. Traders can align their requirements with manufacturers based on customer needs, enabling manufacturers to produce goods that meet market demands effectively. Should consumer preferences shift, businesses can conduct research and innovate new products accordingly. Central to this process is big data, which evolves automatically through transactions, thus lowering the costs associated with data collection and communication across various layers of business. This leads to a significant reduction in transaction costs.

Moreover, the use of cryptocurrencies, digital currencies, digital assets, and intellectual properties is witnessing a dramatic increase in business and trade on a global scale.

IV. Discussion

The United Nations Sustainable Development Goal (SDG) 2030 aims to reduce poverty and inequality while ensuring a safe environment for all. Achieving this goal requires a dual focus: increasing productivity and income to foster individual and national growth, and simultaneously mitigating environmental degradation to promote better health for the global population.

However, there exists a complex relationship between economic growth and environmental health. Increased productivity often necessitates the installation of heavy machinery, leading to a higher consumption of fossil fuels such as oil, coal, and gas to operate these machines and generate electricity. Consequently, while economic growth can enhance real output, it also escalates the consumption of nonrenewable resources, resulting in increased pollution, global warming, and the degradation of environmental habitats.

Importantly, not all forms of economic growth are detrimental to the environment. As individuals and nations experience rising income levels, their capacity to invest in environmental protection increases. This can foster a greater awareness of environmental issues and lead to the development of effective policies aimed at sustainability. Furthermore, advancements in automation and digital technologies can boost productivity while minimizing pollution, enabling higher output with a reduced environmental footprint.

In summary, while economic growth can pose challenges to environmental sustainability, it also presents opportunities for enhancing awareness, developing protective policies, and leveraging technology to achieve a balance between economic development and environmental health.

The International Monetary Fund (IMF) estimates that the global economy contracted by 4.4% in 2020, marking the steepest decline since the Great Depression of the 1930s. To navigate toward a new normal, accelerating economic growth through enhanced productivity is imperative. Increasing productivity is crucial for raising individual and national incomes, thereby restoring growth levels and alleviating poverty and inequality.

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

Achieving GDP growth will require a synchronized approach between industrial production and service sectors. However, the looming risk of future pandemics could challenge this drive for over-productivity, potentially compromising public health and environmental sustainability.

Debates surrounding the limits to growth will likely intensify in the post-pandemic era. In this context, environmental economics begins to view the natural environment as a distinct sector, emphasizing the need to address externalities at the international level. In contrast, ecological economics adopts a more interdisciplinary perspective, integrating ecological factors that influence resource regeneration and waste absorption into economic models.

The concept of the Fourth Industrial Revolution aligns well with the principles of ecological economics. This revolution represents an interconnected system of manufacturing and services leveraging automation and digital technologies. By doing so, it has the potential to enhance productivity, minimize waste, and promote the use of environmentally friendly energy sources.

Emphasizing a green economy within the framework of the Fourth Industrial Revolution can create synergies through integrated automation and digital technologies. This approach could lead to a more nuanced relationship between Gross National Product (GNP), Gross Domestic Product (GDP), and environmental sustainability, paving the way for a more balanced and resilient economic future. COVID-19 has underscored the transformative power of disruptive technologies in business and manufacturing, demonstrating their potential to enhance environmental protection and food production. This experience serves as a model for leveraging such technologies across various sectors to foster a more sustainable world. Embracing the Fourth Industrial Revolution (4IR) technologies can significantly reduce waste and pollution in industrial processes.

However, realizing the benefits of this revolution necessitates substantial financial investment and collaboration, particularly from wealthier nations. A restructured international monetary and financial system that includes participation from both low-income and high-income countries is crucial for facilitating this transition.

For low-income and developing nations, changes in real income could lead to prolonged economic downturns. To effectively adapt to the demands of the 4IR, it is essential to focus on human capital development through education, training, and skill enhancement. Although transitioning to new technologies may result in job losses in some areas, it simultaneously creates new opportunities, making it vital to cultivate national skills across government, public, and private sectors.

The global economy is increasingly shifting toward a knowledge-based model, where innovation plays a pivotal role in capital formation. The adoption of disruptive technologies can significantly enhance value, productivity, and income, aiding socio-economic recovery in the post-pandemic landscape and supporting the achievement of the United Nations' Agenda 2030.

This transformation toward a knowledge-based economy is rapidly reshaping global socio-economic structures. However, it is essential to ensure that this shift aligns with sustainable development goals. Investing in education, training, and skills development is critical for improving productivity and sustainability.

Education serves as a fundamental tool for promoting protective behaviors and countering negative health expectations. A knowledge-based economy requires not only innovation but also ethical standards that support sustainable production and enhance competitiveness. Ongoing research in educational institutions is vital for steering nations toward sustainable innovation.

While technology integration in education has opened new pathways for development, low-income and developing countries often struggle to take full advantage due to financial and policy barriers. For example, during the COVID-19 pandemic, developed nations achieved over 80% access to educational facilities, while less than 30% were available in low-income and developing countries.

Training for teachers, trainers, and employees is crucial for enhancing instructional capabilities. The pandemic has accelerated the adoption of automation, digitalization, and robotics across sectors, including government, healthcare, academia, and manufacturing.

Skill development is essential for national advancement across all sectors. The pandemic has highlighted the potential of disruptive technologies in global socio-economic activities. Countries like Bangladesh, classified as middle-income, are making significant strides in adopting these technologies. By rapidly developing national skills to manage and guide this technological transition, such countries can play a crucial role in alleviating the global economic slowdown.

COMMUNITIES WITH EURPHORBIA MACULATA IN THE NORTH CAUCASUS AND THEIR SYNTAXONIC CLASSIFICATION IN EASTERN EUROPE

Yulia Postarnak

•

Kuban State University, RUSSIA
ecopost@mail.ru

Abstract

The article studies the distribution of the alien species Euphorbia maculata L. in the North Caucasus. The species was first recorded in the region in 2006 and is now widely distributed. This study presents the species relationship to habitats and the floristic composition of plant communities. Communities were compared with similar ones in Europe and a new weed association Euphorbio maculata-Acalyphetum australis ass. nova was analysed. Diagnostic species: Euphorbia maculata, Acalypha australis. Summer-dry trampled vegetation with Euphorbia maculata in crevices of sealed asphalt and tile coating of sandy subsoil (on sandy soils), on gravel ground of tram and railway tracks of the Nortn Caucasus region. The Euphorbia maculata communities are often found in cracks of pavement, laid on sand substrate, asphalt cracks of suburban areas and along highways.

Keywords: biological diversity, digitario sanguinalis-eragrostietea minoris mucina, plant communities, invasion, Euphorbia maculate, Acalypha australis, syntaxonomy, North Caucasus, slit biotype, anthropogenic ecosystems

I. Introduction

Euphorbia maculata is an invasive species that is widely distributed throughout the world. Its natural range covers eastern and southern parts of North America [1], where it is classified as weedy species [2]. Its typical habitat is sand on the seashore, mounds along roads [3]. It has been naturalized in Central and South America, the Middle East, East Asia, New Zealand and Australia. In Europe, *Euphorbia maculata* appeared several centuries ago. In the last two decades, the species has significantly expanded its range [3-6]. In the North Caucasus, the species was first recorded in 2006 [7]. It is found in an environment with sharp temperature fluctuations during the day, different from the general habitat of plants and prefers to grow in open sunny places, digs the tile, crevice and gravel biopaths of railways and highways. *Euphorbia maculata* is a bitter weed of agrocenoses. It inhibits the growth of wheat seeds [8, 9], reduces soybean yields [10], cotton [11], tomatoes (*Lycopersicon esculentum*) and chilli pepper (*Capsicum annuum*) [12].

Climate change promotes the spread of alien species adapted to xerophytization. This is particularly relevant for the Krasnodar Region where a big area is occupied by agrocenoses, which are favorable locations for further invasion of *Euphorbia maculata*. The study of plant communities with *Euphorbia maculata* in the North Caucasus in the context of the European syntaxon of vegetation will help to better understand the patterns of formation of urban flora and develop strategies for management of invasive species. The integration of studied plant communities with *Euphorbia maculata* in the North Caucasus into the European Vegetation Syntaxon will allow a better understanding of the patterns of formation of flora of anthropogenic ecosystems and develop strategies for management of invasive species.

II. Methods

The work is based on 70 relevés, carried out by the author in 2021-2023 in the territory of Krasnodar Region (city of Krasnodar, Novorossiysk, Dzhubga, Big Sochi) of the republic of Abkhazia (city of Pitsunda) (Figure 1).

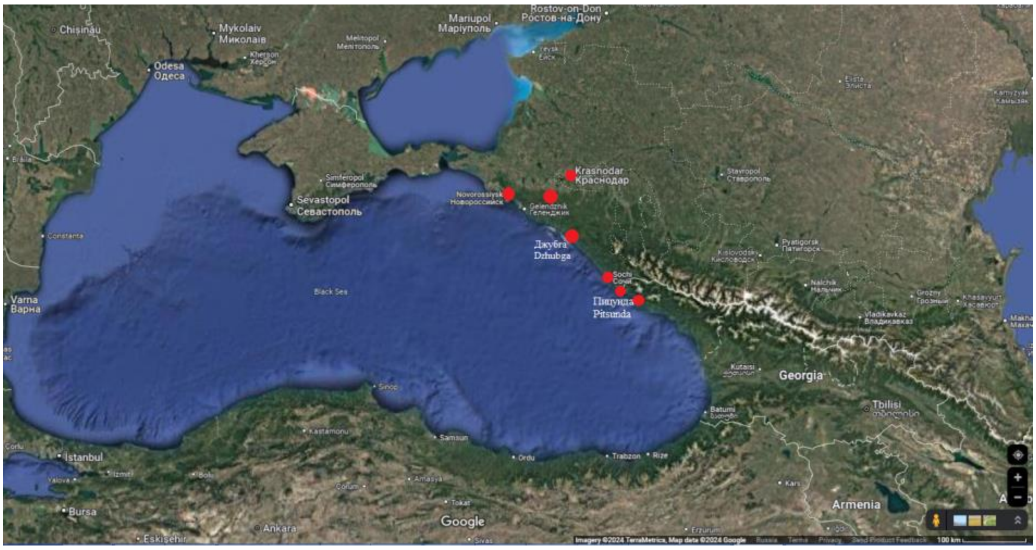

Figure 1: *Distribution of Euphorbia maculate in the North Caucasus*

The cracks between the pavement tiles, which are placed on sand substrate (figure), cracks of railway stations, suburban and residential areas (figure), sidewalks along roads (figure), bridges, city parks were investigated. 23 relevés were selected for the characteristics of the plant species that were studied. The sample area is ranged from 6 to 100 m^2.

In the relevé of the floral composition, the abundance of species was assessed by the Brown-Blank scale: r - single species, mostly only one specimen; + - species are thinned or cover only a small part of the area; 1 - species are numerous but cover up to 5 % or quite thinned, but with a higher coverage; 2 - projective coverage up to 5-25% or individuals are very numerous, but coverage is lower; 3 - projective coverage up to 26-50%; 4 - projective coverage up to 51-75%; 5 - projective coverage more than 75%. The relevés were processed by Brown-Blank [10], using MEGATAB [14] and TWINSPAN [15] software packages. The names of the highest syntaxa are given in «Vegetation of Europe...» [16]. The names of new syntaxa are given in accordance with the rules of the «International Code of Phytocenolological Nomenclature» [17]. Species names are updated according to the summary of S. K. Cherepanova [18].

III. Results

Syntaxa with Euphorbis maculate were first identified in North Korea as ***Polygono-Poetea annuae*** in 1991 [19], which was later reviewed by Vegetation of trampled soil dominated by C 4 plants in Europe – class ***Stellarietea*** [20], in Prodromus of Europe [16] and entered into a new class of anthropogenic vegetation ***Digitario sanguinalis-Eragrostietea minoris*** Mucina, Losová et Šilc in Mucina & al. 2016. Comparison of selected plant phytocoenons of communities with *Euphorbia maculata* with literature data [20] revealed differences in taxa lists (table 1). This made it possible to include them in a new association.

1 ***Euphorbio maculata-Acalyphetum australis***, Russia (this paper), 2 Eup***horbietum chamaesyco-prostratae*** Rivas-Martínez, Madrid, ES, 3 ***Gnaphalio luteo-albi-Polycarpetum tetraphylli*** Ortiz & Rodríguez-Oubiña (1990: Tab. 2) C & N Portugal, 4 ***Euphorbio chamasyce-Oxalidetum corniculatae*** Lorenzoni 1964, 5 ***Polycarpo tetraphylli-Amaranthetum deflexi*** Pignatti 1953, Italy (Poldini, 1989), Croatia (Čarni, 1995), 6 ***Eleusinetum indicae*** Pignatti 1953, 7 ***Euphorbietum maculatae*** Poldini 1989, 8 ***Polygono avicularis-Euphorbietum maculatae*** (Tímár, 1950) Čarni & Mucina (1998), Hungary (Tímár, 1950), (Čarni, Mucina, 1998), 9 ***Eragrostio-Polygonetum avicularis*** Oberd. 1954, 10 ***Portulaco-Euphorbietum maculatae*** (Brandes 1993) Čarni & Mucina (1998)

The position of the characterized communities with Euphorbia maculate in the system of higher syntaxa is presented as follows:

Class ***Digitario sanguinalis-Eragrostietea minoris*** Mucina, Lososová et Šilc in Mucina et al. 2016

Order ***Eragrostietalia*** J. Tx. ex Poli 1966

Alliance ***Polycarpo-Eleusinion indicae*** Čarni et Mucina 1998

Acc. ***Euphorbio maculata-Acalyphetum australis*** ass. nova hoc loco

IV. Discussion

Digitario sanguinalis-Eragrostietea minoris is a new class of anthropogenic vegetation uniting therophyte communities of annual plants in southern non-moral, Mediterranean, steppe and semi-desert zones of Europe (Mucina et al., 2016). Diagnostic types of class: *Amaranthus albus, Anisantha sterilis, A. tectorum, Bromus squarrosus, Conyza canadensis, Corispermum hyssopifolium, Digitaria ischaemum, D. sanguinalis, Echinochloa crusgalli, Eragrostis minor, Eragrostis pilosa agg., Lepidium densiflorum, Panicum miliaceum, Plantago arenaria, Polygonum aviculare agg., Portulaca oleracea, Salsola australis, Senecio vernalis, S. viscosus, Setaria pumila, S. pycnocoma, S. verticillata, S. viridis, S. weinmannii.*

In the Krasnodar Region, the class is represented by the order ***Eragrostietalia*** - communities of juveniles on dry and warm sandy or other drained soils.

Diagnostic types of order = Diagnostic types of class.

According to the latest survey of vegetation in Europe (Mucina et al., 2016) this order has a complex structure of alliances which are divided into 3 groups, combining the segmental vegetation of the temperate zone, segmental vegetation of the Mediterranean and the ruderal vegetation. The investigated phytocoenoses are classified to the Alliance ***Polycarpo-Eleusinion indicae*** Čarni et Mucina 1998.

Ass. ***Euphorbio maculata-Acalyphetum australis*** ass. nova hoc loco (table. 1) Diagnostic species: *Euphorbia maculata, Acalypha australis*.

Type of nomenclature (holotypus hoc loco) - op. 9 in table. 1: *Euphorbia maculata* - 1, *Portulaca oleracea* - +, *Digitaria sanguinalis* - 1, *Polygonum aviculare* - 2, *Eleusine indica* - +, *Setaria pumila* - +, *Acalypha australis* - +, *Conyza canadensis* - +, *Sonchus oleraceus* - +, *Chenopod*ium album - +, *Lactuca saligna* - +, *Crepis setosa* - +, *Plantago major*- +. Krasnodar Region, the city of Krasnodar. 15.07.2023.

Summer-dry trampled vegetation with *Euphorbia maculata* in crevices of sealed asphalt and tile coating of sandy subsoil (on sandy soils), on gravel ground of tram and railway tracks of the North Caucasus region.

This marginal community is often found in the cracks of pavement tiles, laid out on sand substrate (figure), asphalt cracks of adjacent and near the fence areas (figure), sidewalks along roads (figure), bridges, railway platforms, parks. The basis of the grass stand consists of *Euphorbia maculate, Digitaria sanguinalis, Polygonum aviculare, Setaria viridis, Portulaca oleracea* (with abundance 3-15%, on average 7%). The grass stand is thinned unevenly, the total projective coverage is 5-35%. Its height depends on the intensity of poaching and varies from 5 to 40 (60) cm. The average height is 17 cm. The floristic richness of communities is low (10-16 species).

In the associations, the main phytocenotical positions are occupied by the alien plant species *Euphorbia maculate, Digitaria sanguinalis, Acalypha australi, Setaria pumila, Eleusine indica, Ambrosia artemisiifolia, Amaranthus retroflexus, Conyza canadensis, Sorghum halepense, Setaria pumila, Paspalum dilatatum, Juncus tenuis*.

Abstract

In recent years, commercial banks have been actively involved in financing projects related to the green economy, reflecting the global trend of transition to sustainable development.
Many banks are switching to electronic document management and using alternative energy sources for their operations. Despite the positive changes, banks face certain challenges. There is a risk that financing green technologies may negatively affect the performance of traditional companies. The State provides support commercial banks in the implementation of green economy projects.
The Bank of Russia and other government organizations are developing concessional lending programs that allow banks to provide loans on more favorable terms for projects aimed at sustainable development. This may include reducing capital reserve requirements for "green" projects, which makes them more attractive to banks. Commercial banks can receive subsidies to cover part of the interest rates on loans issued to finance environmentally friendly projects. This reduces the financial burden on borrowers and encourages them to implement sustainable initiatives. In some cases, Russian banks may cooperate with international financial institutions.
The implementation of green economy projects by commercial banks is not widespread enough. The successful development of green banking requires an integrated approach, including the adaptation of products, internal processes and corporate culture to new environmental standards. This study is devoted to an overview of the mechanisms and methods of stimulating and implementing green banking.

Keywords: green loans, green finance bonds, certification of green financial products, commercial banks, taxonomy of green projects

I. Introduction

Such instruments as green loans, green finance bonds and certification of green financial products serve the goals of widespread introduction of green banking financing. Green loans are becoming an important tool to support businesses striving for sustainable development and reducing their environmental footprint. Commercial banks are actively developing this area, offering a variety of products that can help both individual entrepreneurs and large companies.

The objectives of financing green economy projects are green construction, environmentally friendly transport, waste management and much more.

Banks can act as organizers of the issue of green bonds by other companies, providing consulting services and helping with the placement of securities. In order to ensure transparency and investor confidence in green financial products of banks, their certification for compliance with the principles and standards of green finance.

Non–financial reporting of clients helps banks reduce the risks of implementing green financing projects and confirm a responsible approach to the implementation of green projects.

Non–financial reporting of banks helps to: establish trust from investors and customers, assess and manage risks; comply with international standards and expectations, which helps to increase their competitiveness in the market. Large Russian banks are already actively implementing non–financial disclosure practices. They publish reports containing not only statistical data, but also information about projects, initiatives and interactions with key stakeholders. This allows them not only to meet the requirements, but also to stand out from the competition. However, a large number of commercial banks have not yet introduced the usual practice of disclosing non–financial information.

Thus, it is relevant to research and develop mechanisms and methods to stimulate and implement green banking for implementation by commercial banks, including creating incentives for private investors and financial organizations.

The purpose of this study is to study the best practices of commercial banking financing of green economy projects and to develop mechanisms and methods for stimulating and implementing green banking for implementation by commercial banks.

The objectives of this study:

– conduct benchmarking of leading countries in the field of green banking, such as Germany, Sweden and The Netherlands, in order to identify the best practices for financing environmentally sustainable projects by commercial banks;

– to investigate the impact of government support on the activity of commercial banks in the field of green banking by analyzing the effectiveness of various subsidy mechanisms and tax incentives;

– compare the volumes and dynamics of green lending in the leading countries of Russia, identifying the key factors contributing to or hindering the growth of this segment;

– to assess the degree of involvement of commercial banks in sustainable development projects through a quantitative analysis of the structure of their loan portfolio and participation in green bonds;

II. Methods and materials

The research uses information data, as well as methods of theoretical research, namely: monographic.

III. Literature review

A lot of research has been devoted to green banking in a wide range of areas, including those that are the focus of this study.

Thus, emphasize that a significant amount of financial resources is needed to promote green projects, in which banks play a key role, acting as active participants in financing projects.

This includes the creation of a "green" banking system that unites various financial institutions, such as "green" banks and development banks. An important aspect is the need to regulate banking activities, including "green" financing, which should be supported by government politicians and banking regulators. This allows you to direct financial flows to sustainable projects and minimize environmental risks.

Some authors notes that Russia, as a participant in the international environmental agenda, should actively develop the green finance market, taking into account international standards and practices [2-14]. The paper points to the underdevelopment of the Russian financial market and the lack of active participation in international organizations, which may hinder this process. Success in the field of green finance can lead to attracting foreign investment and improving the country's reputation in the international arena.

Zaitseva [1], emphasize that banks, being financial intermediaries, cannot stay away from the implementation of ESG projects. However, a full understanding of the importance of the ESG agenda in the banking sector has not yet been achieved. The main factors slowing down development include the poor quality of information for analyzing borrowers.

IV. Results and discussion

The study showed that benchmarking of leading countries in the field of green banking, such as Germany, Sweden and the Netherlands represent a valuable area of research that can enrich Russian banking practice with the best global approaches.

However, despite their successes, the adaptation of this experience to the Russian economy it is associated with a number of challenges due to the peculiarities of the national context.

Germany, one of the largest economies in Europe, has demonstrated outstanding results in the field of green banking, especially in the framework of energy efficiency and renewable energy development programs. The main driver here is government support, expressed in large–scale subsidy programs, guarantees and benefits that make financing green projects more attractive to commercial banks. An important aspect is the participation of such large institutions as KfW Bankengruppe, which not only provides financial support, but also actively participates in the development of sustainable development strategies. This approach minimizes risks for banks and entrepreneurs, providing a high degree of confidence in the return on investment.

At the same time, the adaptation of the German green banking model presents certain difficulties for Russia. One of the key obstacles is the insufficient level of government support and subsidies for green projects, as well as the relatively weak development of renewable energy infrastructure. Unlike Germany, where a significant part of electricity is produced by wind and solar, in Russia the energy sector is still dominated by traditional hydrocarbons.

However, on the other hand, there is potential for growth in this segment, given Russia's rich natural resources, which can be used to transition to more sustainable energy supply models.

Sweden, being one of the most environmentally oriented countries, is actively developing green banking practices. Sweden is a leader in green bond issuance, which helps to raise significant funds to finance sustainable projects. Adapting the Swedish experience in Russia may also face certain difficulties. Firstly, the Russian green bond market is at the stage of formation, and the volume of issues is still significantly behind its Western counterparts. Secondly, the level of awareness and acceptance of ESG principles among Russian companies and banks remains low. Although interest in sustainability is growing, many companies still view ESG as an additional burden rather than an opportunity to create long–term value. Nevertheless, taking into account global trends and the growing interest of investors in sustainable financing, the introduction of ESG factors into Russian banking may become a strategically important area.

The Netherlands, in turn, demonstrates an innovative approach to green banking, actively developing new financial instruments and mechanisms, such as public–private partnerships. Dutch banks cooperate extensively with international financial institutions, which allows them to borrow best practices and integrate them into the national banking system. An important area is the financing of sustainable agriculture and water resources management, which corresponds to the natural and economic conditions of the country.

For Russia, where agriculture and water resources also play an important role, the experience of the Netherlands is of particular value. However, it should be borne in mind that the adaptation of these practices requires significant institutional changes and the development of new mechanisms for interaction between the state, banks and the private sector. Moreover, unlike the Netherlands, Russia faces problems of regional inequality, which can make it difficult to scale successful projects throughout the country. For example, successful green finance models in Central Russia may not be as effective in Siberia or the Far East. In the East, where the infrastructure is much less developed.

It is important to take into account that the successful adaptation of international practices requires an integrated approach, including not only the borrowing of specific financial instruments, but also the creation of an appropriate institutional environment, raising awareness and adoption of ESG principles, as well as the development of public partnerships with the private sector. In this context, the role of the state becomes key, since it is it that is able to set the vector of development and provide the necessary conditions for the growth of green banking in Russia. Fig.1 schematically shows the role of a commercial bank in the field of sustainable development.

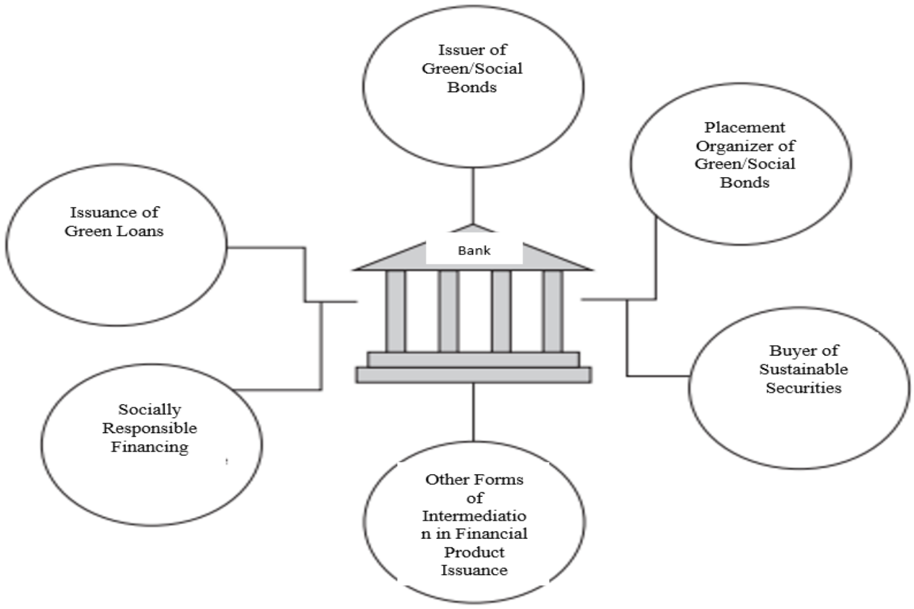

Figure 1: *The role of a commercial bank in the field of sustainable development*.
Source: Zaitseva I.G., Maksimov I.A. Trends in the development of esg–activity of banks // Economics and management. 2022. No.12. URL: https://cyberleninka.ru/article/n/tendentsii–razvitiya–esg–deyatelnosti–bankov (date of application: 08/24/2024).

To quantify the impact of green finance on the financial results of commercial banks, a model based on regression analysis is proposed, which takes into account the volumes of green loans issued and green bonds issued in different countries. The main estimation method is multiple linear regression, where dependent variables (ROA, ROE, profit) will be modeled depending on independent variables.

The general formula of the model:

$$Y_i - \beta_0 + \beta_1 * X_{1i} + \beta_2 * X_{2i} + \beta_3 * X_{3i} + \epsilon_i \quad (1)$$

where,
Y_i − depend variable (e.g., ROA);
X_{1i} – volume of green loans issued;
X_{2i} − volume of green bonds issued;
X_{3i} − share of green financing in the total loan portfolio;
β_0, $\beta_1, \beta_2, \beta_3$ − regression coefficients;
ϵ_i − random error.

The obtained regression coefficients will allow us to assess how changes in the volume of green financing affect the financial results of banks. For example, a positive and significant value of the β1 coefficient will mean that an increase in the volume of green loans contributes to an increase in the profitability of the bank's assets. Control variables can be added to the model, such as the total assets of the bank, interest rates, and the economic situation in the country, in order to take into account external factors that can also affect financial results. After evaluating the model, hypotheses about the importance of green finance for banks' financial performance can be tested.

Also, based on the model, it is possible to make forecasts and assess how an increase in green financing may affect the bank's future results. It is important to keep in mind that the volume of green loans and bonds in Russia is still small compared to other countries, which may reduce the importance of regression coefficients. However, as the green banking sector grows, the model may become an important tool for evaluating the effectiveness of such investments and developing strategies for Russian commercial banks. In order to ensure the rapid growth of the green banking sector, state support for the activity of commercial banks in the field of green banking is necessary, including various mechanisms of subsidies and tax incentives.

Financial institutions are facing new challenges and requirements, and the effectiveness of various subsidy mechanisms and tax incentives is becoming a determining factor for the successful integration of green finance principles into the banking sector. One of the main instruments of government support is subsidizing interest rates on green loans. In a number of countries, such as Germany and France, this mechanism has proven to be highly effective.

In turn, this makes such projects more attractive to commercial banks, reducing their risks and increasing their potential profitability. An example of the successful implementation of this approach is the program implemented in Germany through KfW Bankengruppe, which provides subsidies and guarantees to green projects. Tax incentives are another important mechanism of state support that can stimulate the development of green banking. In countries such as Sweden and the Netherlands, tax incentives are provided not only to enterprises implementing green projects, but also to banks actively involved in financing such initiatives.

However, at the moment their use remains limited, which reduces the motivation of banks to participate in green projects. The introduction of systemic tax incentives for banks supporting sustainable development could It would significantly increase their interest in expanding green lending and issuing green bonds. This, in turn, would create conditions for increasing investments in projects aimed at environmental modernization and reducing the carbon footprint.

Despite the obvious advantages of government support, it must be borne in mind that its effectiveness depends not only on the scale of subsidies and benefits, but also on the quality of program implementation. It is important to ensure transparency and accessibility of support mechanisms so that they really contribute to the growth of green banking, and do not create additional barriers for commercial banks.

The development of green lending in the world today is determined by many factors that differ in their importance and impact on the financial results of banks and the economy as a whole.

Comparing the volumes and dynamics of green lending in leading countries such as Germany, Sweden and the Netherlands with the situation in Russia allows not only to assess the current state of affairs. Such criteria include institutional support, the development of a regulatory framework, the level of awareness of the importance of ESG principles.

Over the past decades, Germany, Sweden and The Netherlands has consistently strengthened its position in the field of green lending, which has led to significant successes in this area. In Germany, the volume of green loans annually shows steady growth exceeding 15–20%.

Which, through state–owned banks such as KfW, provides subsidies and guarantees for green projects, the development of renewable energy sources and sustainable construction. This allows banks to reduce their risks and attract more customers interested in sustainable development. In Sweden, the dynamics of green lending is also impressive, with an annual increase of 12–18 %, and the share of green loans in the total loan portfolio of Swedish banks is 10–12 %.

This was achieved through the active integration of ESG principles into banking practice and government support in the form of tax incentives and special financing programs. The Netherlands shows similar results, with green lending growing at 10–15% per year and significant investment in projects related to sustainable agriculture and water management. At the same time, the Russian green lending market lags far behind its Western counterparts. The volume of green loans in Russia is less than 1% of the total loan portfolio of banks, and the growth rate remains modest, ranging from 5–7 % per year.

These indicators indicate a significant lag, which requires an analysis of the factors hindering the growth of green lending in the country. One of the key barriers is insufficient institutional support. While in In Germany and Sweden, state–owned banks play an active role in stimulating green lending, while such mechanisms have not yet become widespread in Russia. The availability of subsidy programs is limited and access to them is difficult, which constrains banks' interest in this segment. Another important factor is the regulatory framework. Leading countries have long developed and implemented clear standards and taxonomies for green projects, which ensures transparency and reduces risks for market participants.

In Russia, such a regulatory framework is still being formed, and the lack of clear criteria creates uncertainty for both banks and investors. This leads to the fact that banks are afraid to participate in green lending due to high risks and uncertain prospects for return on investment. In addition, the level of awareness about the importance of ESG principles in Russia remains low. In Germany and Sweden, environmental responsibility and sustainable development have long been an integral part of banks' corporate culture and strategy. In these countries, customers and investors are aware of the importance of sustainable development and require banks to meet high standards. In Russia ESG principles are still perceived as additional requirements rather than an opportunity to create long–term value. This hinders the development of green lending, as demand for such products remains limited.

In Sweden and the Netherlands, tax incentives and other financial instruments create additional incentives for banks interested in developing green finance. There are practically no such benefits in Russia, which reduces the motivation of banks to participate in green projects.

Global trends in sustainable development, international commitments to reduce carbon emissions and growing investor interest in sustainable projects create prerequisites for the activation of this segment. The introduction of successful practices from other countries, the adaptation of the regulatory framework, increased government support and increased awareness of the importance of ESG principles can be key factors contributing to the growth of green lending in Russia. Thus, a comparative analysis of the volumes and dynamics of green lending in leading countries and Russia shows that the successes of most countries in this area are achieved thanks to a well–structured system of institutional support, a developed regulatory framework, a high level of awareness of the importance of ESG principles and the availability of economic incentives. In Russia, on the contrary, insufficient government support, a weak regulatory framework, a low level of acceptance of ESG principles and a lack of significant economic incentives are the main barriers. The growth rate of green loans – an analysis of changes in the volume of green loans in dynamics allows us to assess how actively the bank is expanding its sustainable financing programs. Sustained growth indicates a strategic focus on sustainable development. The analysis requires collecting the following data: the total volume of the bank's loan portfolio, the volume of green loans issued, the volume and number of green bond issues

Green Lending Engagement Index (IGC):

$$IGC = \frac{Volume\ of\ green\ loans}{Total\ volume\ of\ the\ loan\ portfolio} \quad (2)$$

Green Credit Growth Index (GRI):

$$GRI = \frac{Volume\ of\ green\ loans\ for\ the\ current\ year}{Volume\ of\ green\ loans\ for\ the\ previous\ year} - 1 \quad (3)$$

Green Bond Engagement Index (IGO): $\mathrm{IGO} = \frac{\text{Volume of participation in green bonds}}{\text{Total volume of the bond portfolio}}$ (4)

Strategic Commitment Index (CSI):

$$CSI = \frac{IGC+IGO}{2} \quad (5)$$

This composite index combines green lending engagement and green bonds, providing an overview of the bank's strategic commitment to sustainable development. The obtained values of the indicators can be used for a comparative analysis of banks. Higher index values indicate a greater degree of involvement of the bank in sustainable development projects development.

The results can be presented in the form of ratings, which will highlight the leaders and outsiders in the field of green finance. The methodology can be used both for internal evaluation of banks and for comparative analysis at the industry level. If applied at the level of the entire banking system, it is possible to create aggregated indices reflecting general trends in sustainable financing. This data can be useful for both regulators and investors interested in sustainable development. The methodology for analyzing green finance should include both retrospective and forward–looking approaches.

The forward–looking approach includes modeling the future growth of green lending based on current trends and evaluating possible market development scenarios. This approach will make it possible to determine which measures can stimulate an increase in the share of "green" loans in the loan portfolio and how actively banks are ready to support the transition to sustainable development. An equally important aspect of the engagement assessment is the analysis of the participation of Russian banks in the issuance of "green" bonds. Green bonds are debt instruments designed to finance environmentally sustainable projects. Participation in the issuance of such bonds indicates that the bank not only supports sustainable development at the lending level, but also actively participates in raising capital for the implementation of environmental initiatives through the capital market.

It is important to note that participation in the issue of green bonds can be either direct, when the bank itself acts as an issuer, or indirect, when the bank supports the issue of third parties by providing guarantees or acting as an organizer of the issue. To quantify the involvement of Russian banks in green bonds, it is necessary to analyze the structure of their investment portfolio and determine what share green bonds occupy in it. Thus, for a comprehensive assessment, it is necessary to analyze not only the volume of bond issuance, but also the structure of the use of borrowed funds. It is also interesting to consider the degree of involvement of Russian banks in international partnerships and projects related to sustainable development. Within the framework of such projects, banks can not only improve their skills in the field of green finance, but also gain access to best practices and technologies that can be adapted for use in the Russian market. This is especially important in the context of the growing global trend towards increased regulation and accountability in the field of sustainable development.

Banks that actively implement ESG principles in their activities have a higher ability to adapt to changing market conditions. Therefore, in order to increase the involvement of Russian banks in sustainable development projects, it is necessary not only to expand credit programs and issue green bonds, but also to invest in the development of internal competencies and corporate culture focused on the principles of sustainable development. Thus, a quantitative analysis of the loan portfolio structure and participation in green bonds allows a deeper understanding of the degree of involvement of Russian commercial banks in sustainable development projects. This, in turn, opens up opportunities for further development of this segment and integration of the principles of sustainable development into banking activities on a long–term basis.

This will not only attract capital to finance environmentally significant projects, but also strengthen the bank's reputation as a sustainable financial institution. The implementation of a monitoring and reporting system for green projects will ensure transparency of the bank's activities and strengthen the trust of investors and customers. In addition, providing technical assistance and advice to clients on sustainable development issues will help them better understand the requirements of green finance and increase their willingness to participate in such projects. It is necessary to adapt international standards of green finance to Russian conditions, taking into account the specifics of the national market. At the same time, it is necessary to actively raise awareness and train the bank's staff on sustainable development issues, which will allow banks to work more effectively with environmentally significant projects. An important aspect is also the introduction of tax incentives for clients implementing projects in the field of sustainable development. This may include benefits and subsidies that will help make green finance more affordable. The active involvement of private investors and the expansion of cooperation with government support programs are also important elements of the strategy for adapting international best practices.

V. Conclusion

Supporting the development of infrastructure for green finance, including project verification and certification systems, will also be an important step towards strengthening the position of Russian banks in this area. Participation in educational and information campaigns on sustainable development issues will help banks not only strengthen their reputation, but also raise public awareness of the benefits of green financing. It is also important to develop non–financial disclosure practices, including sustainability indicators, which will allow banks to meet international standards and investor expectations.

Thus, green projects and Green Banking in Russia are at the stage of formation, which is manifested in the relatively low share of green loans and bonds in the total portfolio of commercial banks. Nevertheless, global trends and international commitments stimulate the growth of interest in sustainable financing, which creates prerequisites for the accelerated development of this segment.

Abstract

This paper examines innovative resource tax approaches as crucial fiscal tools for mitigating unsustainable natural resource consumption. As global ecosystems face increasing pressure from overexploitation, the need for effective policy measures has never been more urgent. Traditional taxation models often fail to account for the environmental costs associated with resource extraction and consumption, leading to detrimental ecological impacts.

This study investigates various resource taxation frameworks adopted in different countries, analyzing their effectiveness in promoting sustainable resource use and environmental conservation.

The paper begins with a comprehensive review of existing literature on resource taxation, exploring concepts such as environmental externalities and the "polluter pays" principle. It then delves into case studies of successful resource tax implementations, focusing on how these measures have influenced consumption patterns and incentivized sustainable practices among businesses and consumers. The analysis highlights the importance of aligning tax structures with environmental goals, demonstrating how innovative tax strategies can drive both economic growth and ecological preservation. Furthermore, the research identifies key factors that contribute to the success of resource tax initiatives, including stakeholder engagement, public awareness, and the integration of tax measures into broader environmental policies. By presenting empirical evidence and real-world examples, the paper illustrates how effective resource taxation can lead to significant reductions in resource overuse and promote investment in renewable and sustainable alternatives.

The findings underscore the potential of innovative resource taxes to serve not only as a deterrent against unsustainable consumption but also as a catalyst for transitioning towards a circular economy. This transition requires a collaborative effort between governments, businesses, and society, emphasizing the importance of transparency, accountability, and shared responsibility in resource management.

Keywords: sustainable consumption, tax incentives, subsidies, corporate sustainability, circular economy, consumer behavior, environmental policy, resource efficiency, green innovation

I. Introduction

In the face of mounting environmental challenges, including climate change, pollution, and the unsustainable depletion of natural resources, the need for sustainable consumption has never been more urgent. Modern consumption patterns, characterized by excessive use of resources, waste generation, and reliance on fossil fuels, have led to significant ecological damage, threatening the planet's ability to sustain future generations. Addressing these challenges requires a shift towards sustainable consumption—defined as the use of products and services in a way that meets present needs without compromising the environment for future generations.

The pursuit of sustainable consumption is inherently complex, involving not just environmental considerations but also economic and social dimensions. It requires a holistic approach that encourages consumers to adopt environmentally friendly behaviors, while also promoting sustainable production practices within industries. Governments, businesses, and consumers all have critical roles to play in creating a more sustainable economy, and at the heart of these efforts are economic strategies designed to influence market behavior.

Economic strategies are powerful tools for shaping both consumer and producer choices. These strategies include taxes, subsidies, financial incentives, regulatory frameworks, and market-based mechanisms aimed at internalizing the environmental costs of production and consumption. For instance, carbon pricing mechanisms such as carbon taxes and cap-and-trade systems are designed to put a price on greenhouse gas emissions, encouraging businesses to reduce their carbon footprint and invest in cleaner technologies. Similarly, green subsidies and tax incentives for renewable energy, energy-efficient products, and sustainable business practices can accelerate the adoption of eco-friendly solutions across industries.

Moreover, economic strategies can drive innovation, fostering the development of sustainable technologies and products that reduce environmental impact. This is particularly relevant as consumer demand for sustainable products continues to grow. Companies are increasingly recognizing the competitive advantage of offering sustainable products, which not only aligns with consumer preferences but also contributes to corporate social responsibility (CSR) goals. Through policies that promote green innovation, economies can stimulate new business opportunities and growth while simultaneously addressing environmental concerns.

However, achieving sustainable consumption is not only about influencing producers; it is also essential to encourage consumers to make environmentally conscious decisions. Economic incentives such as eco-labeling, carbon pricing on consumer goods, and differential taxation (e.g., higher taxes on environmentally harmful products) can help guide consumers toward more sustainable choices. These strategies aim to make sustainable products more accessible and affordable, while discouraging the consumption of goods with a high environmental footprint.

This paper aims to explore the economic strategies that promote sustainable consumption and their potential to reshape consumer behavior, stimulate green innovation, and drive the global transition to a more sustainable economy. The following sections will delve into the various economic tools available, including fiscal policies, subsidies, market-based incentives, and regulatory approaches, providing a comprehensive analysis of their effectiveness. We will also examine case studies from different regions and industries to highlight successful implementations and lessons learned. By understanding the role of economic strategies in promoting sustainable consumption, this paper seeks to contribute to the broader conversation on how to balance economic growth with environmental stewardship and resource conservation.

In conclusion, economic strategies are essential in promoting sustainable consumption, offering a range of tools that can influence both consumer and producer behavior. By aligning market incentives with environmental goals, these strategies can help shift societies toward more sustainable practices, ensuring that economic development does not come at the expense of the planet's long-term health.

II. Methods

To explore the effectiveness of economic strategies in promoting sustainable consumption, this paper employs a mixed-methods approach, combining both qualitative and quantitative analysis. The research methodology consists of four main components: literature review, case study analysis, policy assessment, and data-driven evaluation of economic tools. Each component is designed to provide a comprehensive understanding of how various economic strategies can influence consumer behavior, business practices, and overall market trends toward sustainability.

1. Literature Review

The first stage of the research involves an extensive literature review, focusing on existing academic studies, policy reports, and industry publications that examine the relationship between economic strategies and sustainable consumption. The review aims to identify key economic tools and mechanisms, including taxation policies, subsidies, carbon pricing, and green incentives, as well as their theoretical foundations and practical applications. The literature review also covers consumer behavior theories and market trends to understand how economic incentives can affect decision-making processes and lead to more sustainable consumption patterns.

The review includes sources from multiple disciplines, including environmental economics, behavioral economics, and sustainability studies, to provide a broad, interdisciplinary perspective on the topic. Key areas of focus include:

- The effectiveness of tax incentives and carbon pricing in reducing environmental impact.
- The role of subsidies and grants in encouraging businesses to adopt sustainable practices.
- Consumer responses to eco-labeling, differential pricing, and other economic signals designed to promote green consumption.

2. Case Study Analysis

To complement the theoretical insights from the literature review, this paper conducts a series of case study analyses. These case studies are selected from different regions and industries that have successfully implemented economic strategies to promote sustainable consumption. The criteria for selecting case studies include diversity in geographical location, type of economic strategy used, and the scale of implementation (local, national, or international).

The selected case studies will examine:

- **Carbon Tax in Sweden**: An analysis of how Sweden’s carbon tax has effectively reduced carbon emissions while maintaining economic growth, offering insights into the design of carbon pricing policies.
- **Subsidies for Renewable Energy in Germany**: A case study on Germany’s "Energiewende" program, which provides subsidies for renewable energy development, exploring how financial incentives can transform the energy market.
- **Plastic Bag Tax in the UK**: An evaluation of the UK’s plastic bag tax, assessing its impact on consumer behavior and plastic waste reduction.
- **Circular Economy Initiatives in the European Union**: An exploration of how the EU’s circular economy policies have encouraged businesses to shift toward more sustainable production practices, focusing on material reuse and waste reduction.

Each case study provides empirical evidence on the outcomes of specific economic policies, highlighting the factors that contribute to their success or failure. These examples are used to draw conclusions about the generalizability of economic strategies across different contexts.

3. Policy Assessment

The next step involves assessing the policies and regulatory frameworks that have been implemented by governments and international organizations to promote sustainable consumption. This analysis looks at both mandatory and voluntary policies, such as carbon trading schemes, environmental taxes, eco-labeling programs, and corporate sustainability reporting requirements.

The policy assessment focuses on:

- Evaluating the efficiency and effectiveness of these policies in achieving their intended environmental and economic goals.
- Identifying potential barriers to policy implementation, such as political resistance, market distortions, or unintended consequences.
- Examining how well policies integrate environmental goals with economic growth objectives.

This section also includes an analysis of international frameworks such as the United Nations' Sustainable Development Goals (SDGs), which provide a global context for sustainable consumption efforts.

4. Data-Driven Evaluation of Economic Tools

Finally, the research uses quantitative data to evaluate the performance of specific economic tools, such as carbon taxes, subsidies, and market-based mechanisms, in reducing environmental impacts and promoting sustainable consumption. The data is drawn from national and international databases, including the World Bank, the Organisation for Economic Co-operation and Development (OECD), and environmental agencies.

Key indicators analyzed include:

- Changes in carbon emissions and resource use following the implementation of carbon pricing or tax policies.
- Adoption rates of renewable energy and eco-friendly technologies as a result of subsidies or green financing programs.
- Consumer spending patterns on sustainable products after the introduction of economic incentives or eco-labeling.
- Overall economic performance, including GDP growth and job creation, in regions that have adopted green economic strategies.

By comparing quantitative outcomes before and after the implementation of economic measures, this section aims to provide empirical evidence of their effectiveness. Additionally, statistical models may be used to explore correlations between specific economic strategies and improvements in sustainability metrics.

III. Results

The global imperative to address climate change and mitigate environmental degradation has led to a marked increase in emphasis on supporting eco-friendly practices and sustainable development in recent years. The BRICS countries—South Africa, Russia, India, Brazil, and China—are emerging economies with abundant natural resources. To achieve sustainable development, these nations must navigate the complex relationships between carbon pricing, the financial sector, and the equitable allocation of revenues from natural resource extraction. The dire consequences of the COVID-19 pandemic have exacerbated an already critical climate crisis, as extreme weather events and anthropogenic factors pose significant threats to humanity. These issues interact synergistically, with human activities such as the spread of disease vectors, environmental degradation, and excessive carbon dioxide emissions rendering the planet increasingly perilous for human habitation (Yu et al., 2024).

The need for transformation in our emissions-driven, energy-intensive culture has become glaringly evident due to the pandemic. Policy initiatives should prioritize addressing severe conditions, reducing carbon emissions, and enhancing transparency in the use of renewable energy sources (Muhammad and Dilanchiev Azer, 2023). One such policy measure designed to lower carbon emissions and promote sustainable practices is carbon pricing. By assigning a cost to carbon emissions, we aim to incentivize the economy's shift toward low-carbon and environmentally friendly approaches. However, the effectiveness of carbon taxes in fostering ecologically sustainable economic growth can be influenced by various factors, including the optimal allocation and utilization of revenues generated from natural resource extraction. The distribution of sustainable natural resource rents, or the income derived from resource extraction, significantly impacts fiscal policy and investment decisions. Rental revenues can support sustainability initiatives, such as research and development in green technologies and environmental conservation, thus enhancing the resilience of the financial services sector for long-term, stable growth (Yuan et al., 2023).

This paper aims to examine the roles of carbon taxes and fiscal policy as economic instruments in promoting natural resource efficiency and environmental sustainability. The study is driven by the urgent need to tackle resource depletion and environmental degradation, as well as the recognition of economic tools' potential to effect change. The research acknowledges the complexities involved in policy development and the necessity for a holistic approach to resource management. By conducting a comprehensive review of empirical data, case studies, and policy evaluations, this study seeks to provide valuable insights into the effectiveness of economic instruments in mitigating the environmental impacts associated with resource-intensive industries. In doing so, it contributes to the ongoing discourse on sustainable resource management and policy formulation, equipping policymakers, researchers, and stakeholders with a deeper understanding of the roles that carbon taxation and fiscal policy play in the pursuit of resource efficiency and sustainability (Yu et al., 2023).

IV. Discussion

The research aims to shed light on how economic instruments can incentivize sustainable practices and mitigate environmental externalities in the natural resource sector through thorough examination and analysis. This foundational goal sets the stage for an in-depth exploration of these topics in subsequent sections of the study. Effectively utilizing natural resources while ensuring environmental sustainability is a pressing challenge in today's world. The relentless depletion of finite resources, along with the environmental repercussions tied to their extraction and use, underscores the urgency of this issue. In response to these challenges, policymakers, economists, and environmentalists have been exploring innovative strategies to promote responsible resource management, with economic instruments emerging as a key solution.

This study delves into the motivations behind conducting this research and highlights its significance within the broader context of sustainable resource management. The rapid and often unsustainable exploitation of natural resources has led to a host of challenges (Li and Umair, 2023a, b). The depletion of non-renewable resources, such as fossil fuels and minerals, not only threatens the availability of these essential commodities but also intensifies competition and conflict over access to them (Liu et al., 2023). Furthermore, the extraction and utilization of these resources are closely linked to environmental degradation, manifesting in greenhouse gas emissions, deforestation, habitat loss, and water pollution, among other detrimental effects. The depletion of non-renewable resources could lead to the complete exhaustion of vital economic inputs, disrupting global supply chains and jeopardizing energy security (Taghizadeh-Hesary and Yoshino, 2020). Additionally, the continuous rise in greenhouse gas emissions from resource-intensive industries exacerbates climate change, increasing the frequency and severity of extreme weather events, sea-level rise, and other catastrophic consequences (Zhang and Umair, 2023).

In light of these challenges, the deployment of economic instruments has become increasingly essential as a strategy to address the root causes of unsustainable resource management. Economic instruments encompass a variety of policy tools, such as taxes, subsidies, cap-and-trade systems, and fiscal policies, specifically designed to modify the economic incentives and disincentives associated with resource use (Umair and Dilanchiev, 2022). These tools function by internalizing externalities, meaning they account for the environmental costs related to resource extraction and utilization in economic decision-making.

Carbon taxes represent a significant economic tool aimed explicitly at reducing greenhouse gas emissions. By imposing a carbon price, these taxes create a financial incentive for companies to lower their emissions. The objective of implementing carbon taxes is to align economic incentives with environmental objectives. By leveraging a carbon pricing mechanism, businesses are encouraged to adopt cleaner technologies, improve energy efficiency, and transition to renewable energy sources. Empirical evidence supports the effectiveness of carbon pricing in reducing emissions. For example, research by Usman et al. (2020) indicates that carbon taxes can lead to substantial emissions reductions without adversely impacting economic growth. Case studies from countries like Sweden and Australia demonstrate the success of carbon pricing systems in curtailing emissions from resource-intensive industries.

Fiscal policy complements carbon taxes by offering a broader array of tools to enhance natural resource efficiency. Governments can implement fiscal policies to promote sustainable practices, drive innovation in resource-efficient technologies through research and development, and facilitate the adoption of circular economy principles. The effectiveness of fiscal policies in advancing sustainable resource management is underscored by studies such as Ślusarczyk et al. (2022), which emphasize the importance of integrating fiscal policy tools with regulatory measures to achieve environmental sustainability.

The key contributions of this study include:

- Analyzing the BRICS nations from 1995 to 2018 to assess how fragmented energy policies have supported their needs, with a specific focus on examining the impact of fiscal policy and carbon taxes on environmental degradation. This research seeks to enrich the existing body of knowledge by exploring the previously under-examined relationship between fiscal policy and environmental degradation in BRICS countries, while also highlighting the significance of robust environmental regulations.
- Introducing a novel indicator called consumption-based Environmental Index (EI), which accounts for the effects of global trade, differentiating it from prior studies that utilized a traditional EI. Moreover, this study employs advanced econometric techniques, specifically the Augmented Mean Group (AMG) and Cross-sectionally-Dependent Mean Group (CCEMG) estimators, which effectively handle cross-sectional dependence, heterogeneity, and multicollinearity, thereby ensuring accurate results.
- Utilizing a panel quantile regression model to investigate the socioeconomic factors influencing EI levels in BRICS countries across different quantiles, employing a non-parametric approach that diverges from conventional parametric methods. This method is necessitated by the significant variations in per capita economic instrument rates among BRICS nations.

SUSTAINABLE DEVELOPMENT OF PRIMARY HEALTH CARE SYSTEMS

Marziyat Sarbasheva, Zukhra Makhieva, Aina Maltsagova, Laura Khadzhieva, Magomed Dzhafarov

•

Medical Academy named after Kh.M. Berbekov, RUSSIA
tatyanaacusher@yandex.ru

Abstract

Sustainable development of primary health care systems is the basis for ensuring universal access to health services and improving the health of the population. The most important aspects of a sustainable approach are equity, accessibility and focus on the needs of the local community, which includes both disease prevention and treatment. Key areas of development are strengthening the medical infrastructure, improving the skills of personnel and introducing digital technologies to improve the quality of services. Adopting a strategy aimed at eliminating the social determinants of health helps to increase the resilience of health systems and their readiness to respond to emergencies. Involving the population in decision-making processes helps to more accurately take into account local needs and improve health literacy. Sustainable primary health care systems can significantly reduce health care costs, improve quality of life and contribute to a healthier society.

Keywords: primary health care, sustainable development, universal health coverage, health systems strengthening, health equity, community engagement, health workforce, social determinants of health, health infrastructure, digital health technologies

I. Introduction

Primary health care (PHC) is the foundation of any sustainable health system, providing accessible, comprehensive and equitable health care. The need for PHC development has increased significantly in recent decades due to global health challenges, including demographic changes, the rise of chronic diseases, pandemics and climate change. Sustainable development of primary care systems aims to create flexible and resilient structures that can adapt to the changing needs of society and effectively respond to new challenges.

One of the key challenges is to achieve universal health coverage (WHO), which requires expanding access to quality PHC services for all segments of the population, including vulnerable and disadvantaged groups. Sustainable development of PHC also involves eliminating health inequalities, when socioeconomic factors such as income, education and living conditions affect access to health care and people's health. This requires the implementation of integrated approaches aimed at improving the social determinants of health and involving local communities in decision-making.

The integration of modern technologies and innovations in primary health care also plays a key role in sustainable development. Digital technologies, telemedicine and electronic record-keeping systems can significantly improve the efficiency of health care delivery, especially in remote and hard-to-reach areas. The introduction of such technologies improves coordination between different levels of health care, facilitates timely provision of care and reduces the burden on specialized institutions.

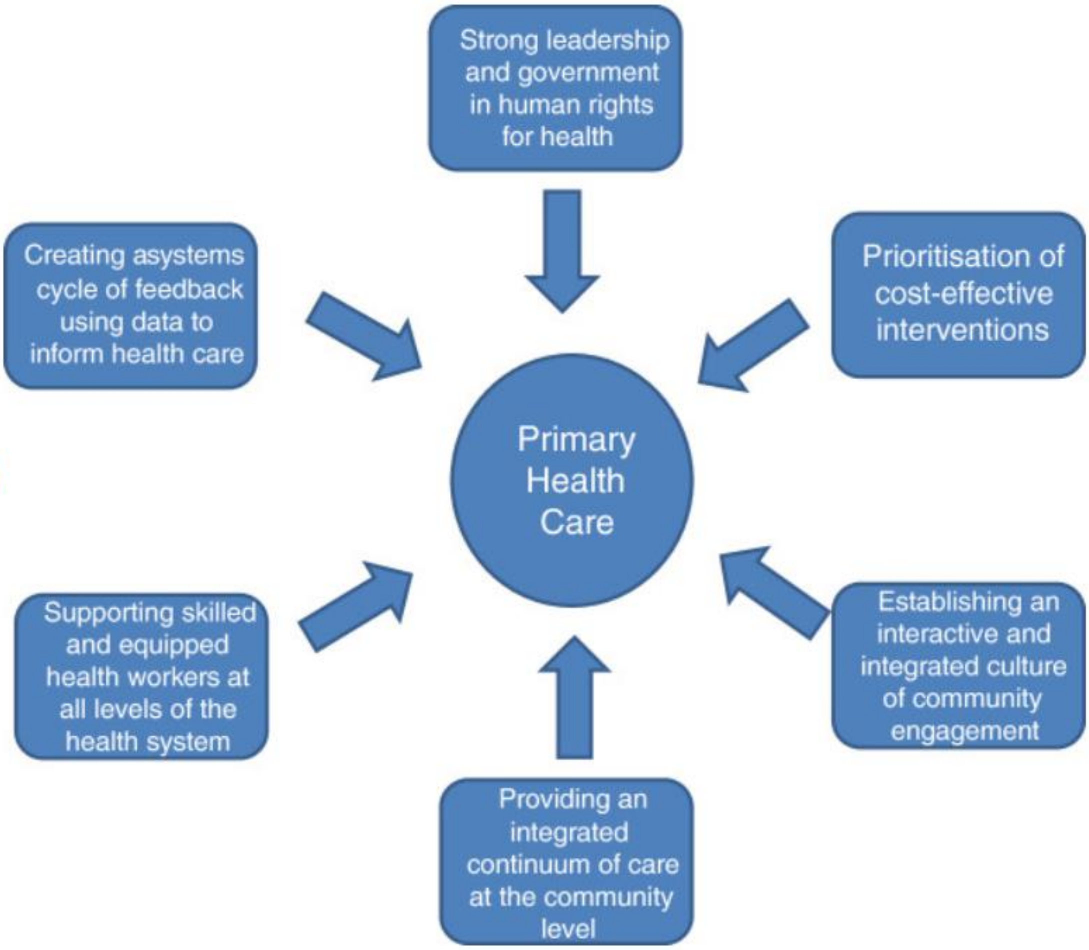

Figure 1: *Core principles & components for effective implementation of primary health care*

However, despite significant achievements, many countries continue to face challenges related to insufficient funding, shortages of health workers and weak infrastructure. These problems are exacerbated by inequalities in access to quality health services, especially in low- and middle-income countries. Developing sustainable primary health care systems requires a comprehensive approach that includes health policy reform, improved workforce training and the creation of stable financial mechanisms to ensure sustainability.

Sustainable development of primary health care is therefore a prerequisite for achieving the Sustainable Development Goals (SDGs) related to health and well-being. This paper examines key strategies and approaches to strengthen PHC systems, including the introduction of technology solutions, policy reform, and community engagement in health governance and decision-making processes.

II. Methods

This study employed a comprehensive approach to analyze the contributions of primary health care to achieving health-related Sustainable Development Goals (SDGs). The methods utilized included:

1. **Literature Review**: An extensive review of existing literature on primary health care and its role in public health was conducted. This involved analyzing peer-reviewed articles, reports from international organizations, and relevant policy documents.

2. **Data Collection**: Quantitative data was gathered from national health statistics and databases, focusing on indicators related to health outcomes, access to primary care services, and SDG progress. Qualitative data was also collected through interviews with healthcare professionals and stakeholders to gain insights into barriers and facilitators of primary health care implementation.
3. **Stakeholder Analysis**: Key stakeholders, including government agencies, non-governmental organizations, and community representatives, were identified and engaged. Their perspectives on the effectiveness of primary health care services and their impact on health equity were sought.
4. **Case Studies**: Specific case studies were conducted in various regions to illustrate best practices and challenges in primary health care delivery. These case studies provided context-specific insights and highlighted successful interventions that align with SDG objectives.
5. **Policy Recommendations**: Based on the findings, policy recommendations were developed to enhance the effectiveness of primary health care services. These recommendations aimed to address identified barriers and promote multisectoral collaboration to achieve health-related SDGs.

The analysis emphasized a holistic view of primary health care, integrating both health service delivery and broader determinants of health to provide a comprehensive understanding of its role in advancing public health goals.

III. Results

The global significance of primary health care (PHC) has grown, proving to be an effective strategy for enhancing community access to health services. Multilateral organizations and national governments have reached a consensus on the fundamental principles of PHC; however, its implementation varies across countries due to the unique characteristics of local health systems. This article is motivated by an investigation into the PHC models and strategies applied in the Americas and an examination of health network configurations from a PHC perspective.

A systematic literature review was conducted utilizing keywords across at least nine databases. Exclusion criteria included languages other than English, Portuguese, and Spanish, and non-refereed articles, while regional gray literature was included. This process identified 1,146 articles, of which 142 were selected after three rounds of analysis. The selected articles were categorized into six thematic areas.

The evidence gathered on health reforms within the region highlights the necessity to strengthen care strategies backed by PHC and resilient care networks that can adapt to the changing needs of the population and respond to medium- and long-term epidemiological trends.

The Commission's deliberations explored ways to use health financing mechanisms to incentivize national health systems to deliver equitable, comprehensive, integrated and high-quality primary health care (PHC). These services should be delivered through platforms that are responsive to people's needs and fully aligned with the goals of universal health coverage (UHC). We argue that countries must invest more and better in PHC, and that the financing mechanisms that support PHC – from resource mobilization and pooling to budgeting, allocation and purchasing – must put people at the centre.

We detail the key characteristics of people-centred PHC financing. We recognize that the scope for reorienting health financing policies towards PHC depends on the economic, social and political context of a particular region, country or subnational level, and that there is no single path to achieving optimal PHC financing.

Thus, the approach to funding must take into account both local conditions and the need to ensure equity and social justice in the provision of primary care.

PHC is based on the principle that health is a fundamental right, emphasizing disease prevention and health promotion while necessitating intersectoral coordination and community involvement. As the first point of contact between the population and the health system, it plays a vital role in health care delivery.

Primary health care (PHC) is regarded as a crucial strategy in the health sector, as it fosters social development, encourages community participation, and promotes overall well-being within societies.

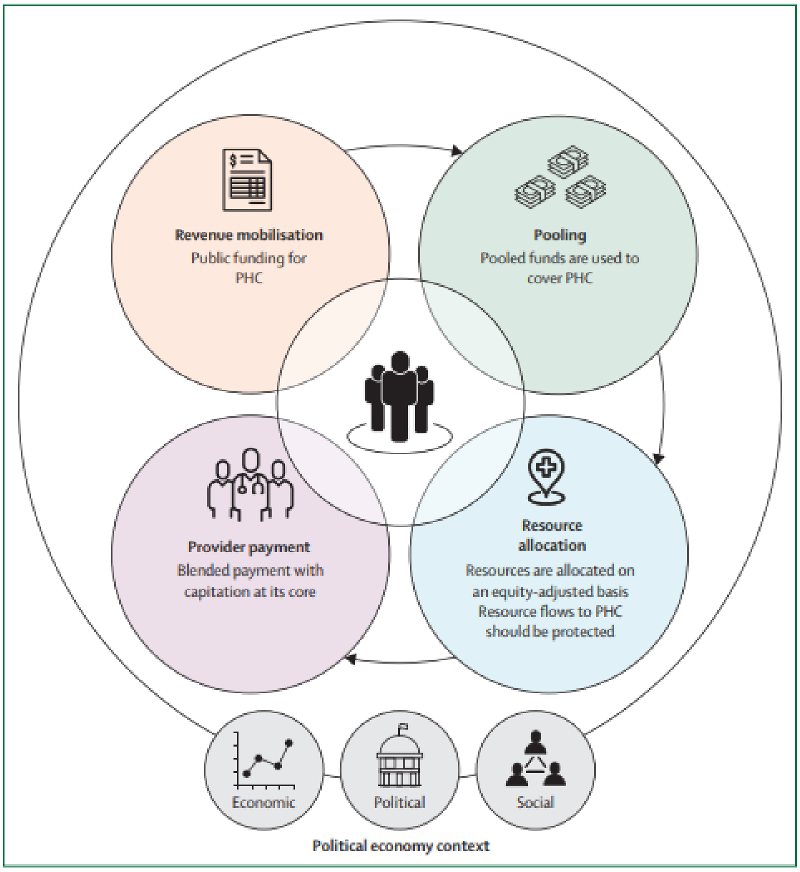

Figure 2: *Framework for people-centered financing of PHC*

Towards the late 1980s, the WHO/PAHO underscored the need to organize health services into various levels of care and develop referral systems to facilitate regional health service planning. The importance of integrated and decentralized care levels was reaffirmed by PAHO Member States in 2005 through the Montevideo Declaration and the Health Agenda of the Americas 2008–2017. The document titled "Integrated Health Services Networks," part of the "Renewal of Primary Health Care in the Americas" series, serves as the foundation for health system reforms that, within the PHC framework, aim to reorient, strengthen, and deepen four primary areas: care models, network governance and strategy, resource organization and management, and economic incentives.

Countries in Latin America have historically faced significant inequalities, not just in health outcomes but also in income distribution, education, access to clean water, and sanitation. By the early 1990s, nearly all Latin American and Caribbean nations had initiated or were considering health sector reforms. Key policies included the separation of functions, decentralization, improvements to health insurance schemes through patient nominalization, and the establishment of explicit service packages. In some instances, these reforms encompassed broader changes to state structures, including national constitutions.

Various studies indicate that health system reforms in Latin American countries have promoted inclusion, citizen empowerment, and health equity, leading in many cases to the establishment of legal rights associated with health and universal coverage, thereby reducing disparities in health indicators among different income groups. Motivated by social justice and equity, civil society has played a pivotal role in advocating for citizen rights and the right to health. An example of this is the work of the Latin American Social Medicine (LASM).

At the international level, several organizations, including PAHO, WHO, UNICEF, and the World Bank, have significantly influenced the region's health system performance and outcomes, promoting the adoption of PHC proposals. With the dawn of the new century, PHC gained even greater global importance as a mechanism for effectively addressing the needs of health systems. Various approaches to PHC implementation have emerged, including comprehensive (CPHC), selective (SPHC), and renewed (RPHC) models.

The comprehensive approach views PHC as part of an integrated health care system linked to the socio-economic development of society, emphasizing cooperation with other sectors. However, it has faced criticism for being overly idealistic and difficult to implement across different communities. The selective approach subsequently emerged, focusing on specific interventions for high-risk populations but lacking the social equity, intersectoral collaboration, and community participation integral to CPHC. Lastly, the renewed approach combines family and community perspectives to strengthen existing health systems, aiming for equity and sustainability in access and the delivery of health services to defined populations and territories, incorporating elements of citizenship, social participation, and empowerment.

IV. Discussion

While access and continuity of care are fundamental goals in any primary care strategy, the high level of unmet health needs among populations relying on both public and private sector coverage highlights that the care demands surpass the capacity of any single provider. Health outcomes—and outputs—are the result of collaborative efforts, requiring the coordination of multiple levels of care and interdisciplinary cooperation. Therefore, implementing effective healthcare networks and ensuring care provision in fragmented systems through a robust regulatory framework are critical elements of a comprehensive primary health care (PHC) strategy.

The complexity of coordinating healthcare networks, which often operate across multiple overlapping jurisdictions as a result of decentralized and/or segmented systems, poses additional challenges. Common obstacles to efficiency in networked healthcare systems include breakdowns in referral and counter-referral mechanisms, the absence of standardized patient information, poor performance of the bodies responsible for coordinating services, a lack of commitment or training among healthcare personnel, and the failure to incorporate perspectives on ethnic and cultural diversity. As a result, understanding why healthcare networks fail requires a comprehensive approach.

Key elements that contribute to the effective functioning of healthcare systems include financial incentives and mechanisms for integrating new technologies. Financial incentives, along with a wide array of policies aimed at strengthening healthcare careers, can encourage healthcare workers to adopt preventive practices, make sound diagnostic decisions, and provide informed treatment. Reputation-based incentives also play a role, particularly when performance data on healthcare professionals is made public. Technology integration has proven beneficial in facilitating learning, promoting cooperation, and improving monitoring procedures, especially in rural areas, complementing care at the primary level.

Beyond this, the presence of multiple jurisdictions within a network raises important discussions about the vertical integration of services, not only in terms of ownership but also in governance, oversight, and coordination. When funding sources are not aligned, service integration must focus on establishing regulatory and procedural links to distribute tasks and responsibilities effectively, ensuring complementarity and requiring a shared monitoring framework.

Thus, network governance becomes a crucial aspect for managers and policymakers to consider when setting priorities in a PHC plan. Strong leadership is essential to bring together different interests and change entrenched practices, serving as the foundation of network governance. The institutional design of regional health systems, political and economic conflicts, and the values of the involved actors are all critical factors that shape the regulation of PHC. Consequently, disconnects between stakeholders and weak leadership within health systems influence the effectiveness of PHC strategies.

Since 1978, the concept of primary health care (PHC) has undergone various interpretations and definitions, causing confusion in the understanding of the term and its practical application. To ensure more coordinated action at the global, national and local levels, the following definition has been proposed:

"PHC is an integrated approach to health that covers the whole of society and aims to achieve equitable access by every member of society to the highest possible level of health and well-being. It addresses the needs of the population at the earliest stages, providing a wide range of services, from health promotion and disease prevention to treatment, rehabilitation and palliative care, as close as possible to people's daily lives." This definition has been developed by WHO and UNICEF within the framework of the PHC concept for the 21st century, with a focus on achieving universal health coverage (UHC) and the Sustainable Development Goals (SDGs).

The PHC system includes three interrelated components:

1. A comprehensive set of health services, with an emphasis on primary health care, public health and related functions.
2. Intersectoral policies and actions that address the key determinants of health.
3. Engaging and empowering individuals, families and communities to actively participate in managing their health and social lives.

The concept of PHC is based on the values of social justice, equity, solidarity and cooperation. It is based on the recognition that the enjoyment of the highest attainable standard of health is a fundamental human right, regardless of status or condition. Achieving true universal health coverage requires a shift from disease-focused systems to people-centred and participatory systems. This requires governments at different levels to recognise the importance of action beyond the health sector to implement a whole-of-government approach to health, with a particular focus on equity and the entire life course. The concept of PHC aims to address a wide range of determinants of health and pays attention to the integrated aspects of physical, mental and social health. This approach ensures high-quality and comprehensive care at all stages of a person's life, not just the treatment of individual diseases, with a focus on maximum proximity to the patient's place of residence.

While there have been notable achievements in building primary health care (PHC) systems and health networks in Latin America, as reflected in key health indicators, there are still critical issues that need to be addressed based on the evidence analyzed. First, while the concept of PHC is embedded in institutional discourse and sectoral debates across the region, it faces significant challenges from the organizational structures of health systems. Intense fragmentation, ineffective decentralization, and the accumulation of isolated programs along the care continuum have led to the consolidation of a care model that deviates from best practices.

Profound income inequality acts as a segmentation mechanism, creating different levels of coverage based on individuals' ability to pay. In recent decades, most countries in the region have made efforts to promote coordinated care models, but results have been uneven, and monitoring and evaluation of the impact achieved have been scarce. The limited coordination between subsystems amplifies disparities, leading to the development of fragmented health networks that often operate informally and without standardized protocols. Collaboration between providers within different subsystems is minimal, and the private sector does not function as a space for coordination and complementarity with the public sector or, in some cases, social security systems. Instead, it often exacerbates care gaps.

The evidence gathered for this review has highlighted several key themes discussed throughout the document. Most notably, there is a pressing need to strengthen PHC models and care networks, as indicated by the documented results. Additionally, the review identified gaps in coverage of other critical topics, such as how health systems adapt to evolving population needs and the accumulation of epidemiological challenges, including mental health issues, addictions, and environmental impacts.

Furthermore, this review found a lack of literature on the impact of financial and non-financial incentives on health service provision, resource allocation efficiency, and quality improvements, opening avenues for future research. This gap suggests a need for deeper interaction between research and political action in the Latin American and Caribbean region to facilitate information exchange, strengthen the evaluation of interventions, and jointly design a research-action agenda that has a meaningful social impact.

Abstract

The article discusses the issues of ensuring security at the regional level, which are quite complex and related to reforms in the economic, social, and environmental spheres. The analysis of the views of researchers whose scientific works relate to the coverage of the problems of ensuring social, environmental, and economic security is carried out. It has been established that socio-ecological-economic security should be understood not only as restoring the broken relationship between man and nature and harmonizing their coexistence, contributing to the measured, reasonable use of the resources available on the territory by man, but also ensuring a balance at a level to which a person can adapt physically, without losses (social, economic). The author's definition of the concept of "socio-ecological-economic security of the region" is presented and the features of its provision on the basis of sustainable development are revealed.

Keywords: economic development, regional policy, sustainable development, environmental safety, nature management

I. Introduction

The environmental situation not only in our country, but throughout the world became so aggravated at the end of the 20th century that at the beginning of the 21st century, the leading countries of the world are forced to look for opportunities to influence all entrepreneurial projects to ensure environmental safety. Moreover, we are talking about achieving sustainable development, when, without yielding in competition in various markets, companies will implement environmentally friendly technological measures. The problem of ecology is an important aspect of the existence of any country. In order to ensure normal ecological and economic living conditions for people, the concept of sustainable development was developed, which has been trying to implement in countries of all continents for several decades. The concept of sustainable development can play an important role in determining regional priorities and strategies for their socio-economic development of the regions.

The dominant vector of the fundamental vector of the regional policy of sustainable development is the imperative to preserve the functioning of the ecosphere (habitat) at a safe and sufficient level to meet the needs of mankind.

II. Methods

The problems of ensuring security at the regional level are quite complex and are associated with reforms in the economic, social, and spiritual spheres. This is especially relevant now, when there is a strengthening of the role of regional development in the implementation of the socio-economic and environmental policy of the state by ensuring socio-ecological-economic security and determining its impact on the sustainable development of territories.

Numerous works of domestic and foreign researchers are devoted to the problems of sustainable development. They are mainly concerned with sustainable development at the global level and at the level of countries and regions. However, there are also scientific studies on the implementation of the principles of sustainable development in the activities of enterprises. For example, in [3], the authors explore the relationship between human capital management and sustainable development, substantiating environmental management of human resources and management of human capital recovery at enterprises as a tool for sustainable development at the micro level. The essence of sustainable development of the enterprise is explained on the basis of ensuring the increase in human capital and the preservation of natural resources for future generations in work [8]. On the other hand, the economic feasibility of implementing the global goals of sustainable development at the level of each individual enterprise through the mechanism of public-private partnership is substantiated in the work [5]. The paper [6] substantiates the expediency of diversifying the sources of financial support for the sustainable development of the enterprise.

Of particular importance are scientific works in which the mechanisms of sustainable development of enterprises and regions or the economies of countries are integrated, since they make it possible to achieve synergy of a combination of multi-level systems of socio-ecological-economic development. For example, the work [2] demonstrates the scientifically based possibilities of forming an enterprise development strategy in such a way as to ensure the sustainable development of the region. The assessment of the impact of risk factors on the sustainable development of enterprises and its economic and mathematical formalization is given in [4].

However, most scientific works relate mainly to certain aspects and most often have a descriptive nature of the problems of ensuring social, environmental, and economic security. For a more detailed analysis, there is a need to consider the integral concept of "socio-ecological-economic security" as one of the most important needs for sustainable development of regions.

The main purpose of the article is to study the fundamental principles and priority areas of ensuring the socio-ecological-economic security of the region as a condition for sustainable development.

In 2015, at the UN summit on sustainable development, the sustainable development paradigm of preserving available resources for future generations was decomposed into 17 global goals that humanity needs to achieve. Thus, it can be argued that over the past 32 years, sustainable development has not lost its relevance, but continues to be the main ideology of our time, which has acquired more specific contours in the expression of global goals. In turn, the global goals for overcoming poverty, hunger, providing quality education and others require a search for mechanisms and tools for their implementation. If the global economic system is not reorganized in accordance with the principles of sustainable development as a socio-economic-ecological balance, then it will face an economic recession, environmental depression and social instability.

The formation of a highly civilized society today is impossible without solving the problem of environmental security, which is one of the main problems not only in the national economy, but also in the system of world economic relations as a whole. The intensification of globalization in the world economy causes the aggravation of the problem of protecting the environment from the consequences of anthropogenic human activity. Sustainable development of the economy involves such changes in the technological re-equipment of production that will not affect the environment and will not have a negative impact on the life of people, and will not interfere with life and reproduction of the natural environment. To meet these requirements, the world community has adopted a number of international agreements, to which our country has acceded.

One of the leading areas of sustainable development is the preservation of the environment, which is most influenced by man-made factors, and their sources are industrial enterprises. The implementation of measures aimed at changing the technological schemes of production taking into account the requirements of sustainable development undoubtedly requires significant financial resources. It is well known that the enterprises themselves are not able to financially support environmental protection programs. Expenditures on environmental protection measures are perceived by them as a diversion of working capital and the creation of prerequisites for a decrease in solvency. They need appropriate funds, which can be obtained, including at the expense of credit funds. Instead, the problem usually arises that environmental measures are not profitable. Only a change in the production apparatus (equipment, composition of raw materials, etc.) can serve both to make a profit and to protect the environment.

III. Results

The effectiveness of the implementation of environmental programs depends on the influence of such institutional factors as the level of education and culture, public awareness, the desire of the population to influence environmental policy in the state, historical and national traditions, the experience of other countries, the structure and functions of state bodies, regulatory legal acts and the right of ownership of natural resources. A successful combination of all the above elements will make it possible to obtain optimal results in the implementation of environmental programs. It should be noted that it is not enough to change or improve the vector of action of only individual official and unofficial restrictions (for example, legislation or the powers of public authorities), it is necessary to correct the influence of the entire set of factors. In order to finance environmental projects, it is necessary to use the partial receipt of funds from enterprises polluting the environment by motivating them to ecologize production and allocating funds for environmental protection measures. The model of motivation of business entities is based on the use of various groups of administrative regulators and economic instruments. The above approach provides for the use of coercion of entrepreneurs to reduce environmental pollution through prohibitions and restrictions, and the further introduction of incentives (provision of benefits) to environmental activities. The best results can be achieved with an adequate combination of economic interest with control and coercion.

Sustainable development should be aimed at achieving a high quality and safety of life of the population, a clean environment with positive dynamics of a set of indicators of sustainable development - indicators that make it possible to judge the state or changes of an economic, social or environmental variable. In the context of this study, the integral index is considered - socio-ecological-economic, with the help of which it is possible to comprehensively judge the development of the region. With this in mind, each economic project should be supported by appropriate technological support, taking into account socio-environmental-economic security.

In view of this, in the work the author [7] appropriately notes that the economy should be environmentally safe, and the environment should be economically feasible. In this aspect, the model of development of the country and its regions, based on a combination of social, environmental and economic policies, is of the greatest relevance and significance.

According to another scientist [8], such a model of sustainable development is possible only in the case of the formation of the noosphere (the sphere of reason), where the measure of national and individual wealth will be the spiritual values and knowledge of a person living in harmony with the environment. And since this is a prospect of the distant future, it is proposed to implement the idea of security as one of the most important basic needs of mankind in the conditions of the present. According to the Constitution of the Russian Federation, "The dignity of the person is protected by the state. Nothing can be the basis for its derogation" [1]. Security is becoming an all-encompassing category that unites most of the problems of protecting the population from any threats. Security is primarily the result of active intraregional social and political stability and effective economic development of the region.

It is within the region that it is possible to establish an optimal combination of social, environmental and economic types of security, which are closely interrelated and affect each other in a single concept of "socio-ecological-economic security". Accordingly, the state of each type of security acts both as a condition and as a consequence of the development and functioning of the other two.

IV. Discussion

The initial thesis of the above is the recognition of socio-ecological-economic security as the main prerequisite for the sustainable development of the region, which includes a set of actions and a set of appropriate measures, processes that ensure the prevention and neutralization of real and potential threats to regional interests. Socio-ecological-economic security establishes the relationship between man and nature and harmonizes their coexistence, as well as contributes to the measured, reasonable use of the resources available in the territory by man. Socio-ecological-economic security reveals the integral potential of the territory as an important factor in its sustainable development.

Thus, the synthesis of all the above characteristics makes it possible to understand socio-ecological-economic security not only as establishing a broken relationship between man and nature and harmonizing their coexistence, contributing to the measured, reasonable use of the resources available in the territory by man, but also ensuring a balance at a level to which a person can adapt physically, without losses (political, social, economic).

Socio-ecological-economic security in the regional dimension provides for the identification of its features due to the presence, in addition to the generalizing criteria for ensuring such security, of specific grounds that affect the strengthening or weakening of the state of security in a particular region. Among the factors of socio-ecological-economic security of sustainable development of the region, the following should be highlighted:

– economic – the level of economic development of a particular region and its disproportions that arise between regions in one way or another; stability of the economy, providing for the reliability of all elements of the economic system, protection of property, creation of guarantees for effective entrepreneurship;

– social – factors of indirect influence of the economic and geographical location of the region. That is, such a factor provides for a sufficient amount of material benefits, social guarantees necessary for the life and reproduction of the potential of the population living in certain regions;

– environmental – preservation of an optimal habitat, expanded reproduction of renewable resources of the biosphere, development of alternative production technologies; ecologization of all spheres of human activity, development of an organizational and economic mechanism for the use of natural resources, environmental and resource profitability; development of environmental awareness and culture.

It is impossible to abstract from the relationship between environmental and economic security, since they are components of the national security of the country. Their interrelation consists in determining the measure of responsibility for compliance with the proper state of environmental safety by business entities at all levels of their interaction. In this case, the concept of environmental safety is directly related to the anthropogenic activity of society, its socio-economic, cultural and historical consequences and measures to overcome them. At the same time, the problem of environmental safety is actualized at all levels without exception - from the micro level to the global level, that is, it is characterized by a hierarchy of goals, tasks and means of solving them.

The problem of preserving the human habitat is important for both present and future generations. Therefore, it is necessary to find a way out, for which it is worth paying attention not only to environmental measures, but also to the replacement of technological schemes. To protect against harmful emissions, there is no alternative to the need to introduce treatment facilities, all kinds of filters, aerators, etc. However, this first direction is unlikely to ever directly serve to obtain a source of repayment of funds to credit institutions. The second direction – lending to the technological process taking into account the requirements of environmental protection – can ensure profit and thus directly serve as a source of funds for settlements with creditors.

Ensuring the socio-ecological and economic security of the region is possible only when the interests of all participants in the process of regional development are taken into account - enterprises, industries, cities, districts, etc.

State regulation of the development of regions should be considered a purposeful systematic influence on the part of the state aimed at maintaining the socially oriented, sustainable and balanced development of the regions in order to ensure the highest and most equal social standards of life of the population regardless of place of residence, which consists in the creation of the necessary regulatory framework, institutional, information and personnel support for the development of regions. The use of program-target methods and appropriate financial and economic tools. Intensification of the use of the regional potential for the development of the territory should take place in the following directions: increasing the efficiency of the functioning of the system of managing the socio-economic potential in the regions; search for the optimal balance of local, regional and state interests; improving the methods of forming local and regional markets and their infrastructure in the context of ensuring the competitiveness of the national economy; formation of investment policy taking into account the specifics of specific regions; formation of an effective system of property management of various forms of ownership; intensification and improvement of the efficiency of the use of local resources.

The priority tasks of the regional policy aimed at improving socio-ecological and economic security are the development and implementation of long-term development programs: the development of both the most profitable and promising industries at the moment, and industries with long-term economic advantages; linking the development of the social sphere at its own expense with state regulation and subsidies for social development; protection of the natural environment and vital human interests from the possible negative impact of economic activity.

In the course of implementing these tasks, in order to ensure the socio-ecological-economic security of the region, it is necessary to adhere to the principles aimed at: improving the legal framework for ensuring the adoption of unequivocal decisions in the event of conflict situations; preservation of resource potential, restoration and development of the production potential of the region; development of the budgetary and financial policy of the regions; training of qualified personnel; conducting a comprehensive environmental assessment of the territory; environmental monitoring; creation of a cadastre of natural resources in the form of databases and a set of maps compiled using GIS technologies; implementation of a specialized system of public administration.

Along with the above, it is worth determining the basic indicators that characterize the level of development of socio-ecological-economic security, a comprehensive assessment of which will allow us to talk about the level of this type of security in the region. Only in this case will the analysis of the socio-ecological-economic security of the region reflect quantitative and qualitative changes. The complexity of developing such a methodology is associated with the set and accounting of a variety of multidirectional indicators.

As a basis for an objective assessment of socio-ecological-economic security, it is proposed to use the procedure of indicative analysis, which allows not only to assess the level of security, but also to compare it with other regions. The system of public management of socio-ecological-economic security in the context of sustainable development of the region provides for the formation of indicators related to various spheres of life. It is within the region that the indicator of the quality of life of the population should be, on the one hand, an integral indicator of the socio-economic development of the region, and on the other hand, a criterion for assessing the socio-ecological and economic security of the region.

To this end, it is proposed to identify blocks of indicators that characterize the level of quality of life of the population, in particular, blocks of complex indicators, such as: socio-economic development; entrepreneurial activity; balanced distribution of income; environmental safety; material well-being and level of consumption; demographic situation; social infrastructure; public health. Methodologically, it is important to ensure the conduct of information-analytical and mathematical-statistical studies of this process in the case of determining indicators of the quality of life of the population, which is one of the necessary components of assessing the socio-ecological security of the region. A comprehensive analysis of the quality of life of the population is determined in dynamics by years and in mutual comparison, which provides additional arguments for making management decisions and determines the degree of threat to the socio-ecological-economic security of the region. In general, the highest indicators of integral indices of the quality of life mean the presence of real potential in the use of available environmental, economic, social, and administrative resources.

The fundamental task of the sustainable development strategy is to ensure the conditions for the balanced functioning of the social, economic and environmental components of the "society-economy-nature" system. Among the basic conditions for sustainable development is equalizing the level of quality of life in different countries and ensuring the growth of well-being in the future. Therefore, poor countries need to step up their efforts and catch up with more developed countries. But improving the quality of life must be based on new scientific advances, especially in the context of the fourth industrial revolution. Modern conditions require everyone to reduce resource consumption, switch to alternative types of materials and energy sources, introduce advanced resource-intensive waste-free technologies, reducing the burden on the environment and human health.

The study made it possible to propose a definition of the concept of "socio-ecological-economic security of the region" as a state of dynamic balance and security, in which the available opportunities to protect the territory from the negative impact of external and internal destabilizing factors are based on a "reasonable" balance between maintaining a favorable ecological environment, economic growth rates and ensuring social standards and guarantees in conditions of sustainable development of the region. Taking this approach as the basis for the regional level, it is proposed to continue and deepen theoretical and methodological studies of indicators of socio-ecological-economic security in the regional dimension, to develop a universal integral indicator of the level of socio-ecological-economic security, which would most fully reflect the state of socio-ecological-economic security of each individual region of our country.

Abstract

The concept of a green economy plays a pivotal role in advancing the Sustainable Development Goals (SDGs) by promoting environmentally sustainable economic growth while addressing social and environmental challenges. This article explores the prospects and challenges businesses face in transitioning towards a green economy. It highlights how adopting green practices can lead to innovation, resource efficiency, and new market opportunities, while also addressing climate change, pollution, and resource depletion. However, businesses must also confront obstacles such as high initial investment costs, regulatory complexity, and the need for technological advancements. The paper examines case studies from various industries to demonstrate successful implementations of green strategies and provides recommendations for businesses to align with global sustainability objectives. By embracing green economy principles, companies can enhance competitiveness, contribute to environmental preservation, and support the achievement of the SDGs.

Keywords: green economy, sustainable development goals (SDGs), business sustainability, environmental sustainability, resource efficiency, climate change

I. Introduction

The growing awareness of environmental degradation and the need for sustainable development has brought the concept of the "green economy" to the forefront of global economic discourse. As the world faces pressing challenges such as climate change, resource depletion, and social inequality, the green economy offers a pathway to align economic growth with environmental sustainability. Central to this approach is the achievement of the Sustainable Development Goals (SDGs), a global framework set by the United Nations to address critical issues such as poverty, hunger, environmental protection, and social equity by 2030.

A green economy promotes economic development that minimizes environmental risks and ecological scarcities while fostering social inclusiveness. By integrating sustainable practices into business operations, the green economy seeks to decouple economic growth from environmental harm, ensuring that future generations have access to the resources and opportunities needed for their own development. For businesses, this shift represents both a challenge and an opportunity. On the one hand, companies are confronted with the need to adopt cleaner technologies, more efficient resource use, and more responsible corporate governance. On the other hand, these changes open up new markets, drive innovation, and enhance long-term competitiveness.

This paper examines the role of the green economy in achieving the SDGs, with a particular focus on the opportunities and challenges for businesses. By analyzing case studies and reviewing current trends, the paper aims to highlight how businesses can contribute to a greener future while maintaining profitability and market relevance. The discussion will also explore the regulatory, financial, and technological barriers that must be overcome for the green economy to become a mainstream model of economic development.

II. Methods

To explore the role of the green economy in achieving Sustainable Development Goals (SDGs) and to analyze the prospects and challenges for businesses, a comprehensive methodological approach was adopted. This approach includes both qualitative and quantitative research methods, structured around the following key components:

1. Literature Review:

A thorough review of existing literature was conducted to identify the theoretical foundations of the green economy and its relationship with the SDGs. Sources included academic journals, books, and reports from reputable organizations such as the United Nations, World Bank, and various environmental NGOs. This review provided insights into the current state of knowledge and highlighted gaps that the study aimed to address.

2. Case Studies:

Several case studies of businesses that have successfully integrated green economy principles into their operations were selected for in-depth analysis. These case studies span various sectors, including renewable energy, sustainable agriculture, waste management, and green technology. The selection criteria included businesses known for innovative practices, measurable impacts on sustainability, and alignment with specific SDGs.

3. Surveys and Questionnaires:

Surveys were distributed to a diverse range of businesses, including small, medium, and large enterprises, to assess their awareness, implementation, and challenges related to green economy practices. The survey included questions on:

- Current sustainability initiatives.
- Perceived benefits and challenges of adopting green practices.
- Financial investments and returns on sustainability initiatives.
- Awareness of regulatory frameworks and incentives related to the green economy.

4. Interviews:

Semi-structured interviews were conducted with key stakeholders, including business leaders, sustainability experts, and policymakers. These interviews aimed to gather qualitative insights into:

- The motivations behind adopting green practices.
- The barriers encountered during the transition to sustainable business models.
- Perspectives on governmental support and incentives for the green economy.

5. Data Analysis:

Quantitative data collected from surveys were analyzed using statistical methods to identify trends and correlations between green economy practices and business performance. Qualitative data from interviews and case studies were subjected to thematic analysis to extract common themes and insights.

6. Comparative Analysis:

The study conducted a comparative analysis of businesses operating in different regulatory environments and economic contexts to understand how these factors influence the adoption of green practices and the achievement of SDGs.

7. Policy Review:

An examination of existing policies related to environmental sustainability and economic development at national and international levels was undertaken. This review helped to contextualize the role of government in facilitating or hindering the transition to a green economy

By employing this multifaceted methodological approach, the study aims to provide a robust understanding of the interplay between the green economy, sustainable development, and business practices, ultimately contributing to the broader discourse on achieving the SDGs.

III. Results

In 1992, the United Nations Conference on Environment and Development highlighted national strategies for achieving sustainable development within the context of the key principles established by the Rio Declaration and Agenda 21. Despite significant efforts by governments worldwide and international cooperation to support these strategies, many nations continue to face concerns and challenges related to ecological sustainability and economic growth. This includes the recent crises in fuel, food, and finance, along with the effects of climate change, resource depletion, and the destruction of ecosystems and biodiversity. Governments around the globe have made various attempts to find effective solutions to help their nations recover from these crises while addressing biodiversity issues and ecological constraints. Consequently, there arose a need for a new concept that encompasses these concerns.

Since its introduction in 2008, the Green Economy (GE) concept has garnered significant international attention, particularly as a response to the financial crisis, and was further emphasized at the UN Conference on Sustainable Development (Rio +20) in 2012. The UNEP defines GE as an approach that integrates three critical aspects: human capital, environmental health, and social equity. The transition to a GE has been a subject of debate, with certain misconceptions surrounding it. For instance, some believe that there is an unavoidable trade-off between environmental sustainability and economic growth. Others argue that the transition to a GE is prohibitively expensive for developing nations and that it could hinder their economic growth, serving primarily the interests of developed countries.

However, a UNEP report from 2011 indicated that macroeconomic projections showed transitioning to a GE could lead to increased growth, job creation, and poverty reduction within a few years. In a GE framework, income growth per capita and employment levels depend on new private and public green investments that are less reliant on the exploitation of natural resources and environmental assets, while also lowering carbon emissions and promoting efficient energy use to mitigate environmental degradation. This approach can enable countries to attain more sustainable economic growth.

Consequently, many developing nations have embraced GE as a new model for economic growth aimed at achieving sustainable development, benefiting various sectors, including renewable energy and agriculture. In the renewable energy sector, solar PV power is expected to become one of the most significant global energy supply sources by 2030 and a leading energy provider by 2050. As part of this vision, China plans to develop a photovoltaic industry with a cumulative installed capacity of 1,050 GW by 2030, positioning itself as a top producer of solar PV technology and the largest exporter, with over 98% of its production sold internationally.

Similarly, Malaysia is enhancing energy access for impoverished communities in rural areas, exemplified by successful renewable energy projects in places like Bario Asal. The Egyptian government aims to produce approximately 42% of its electricity from renewable sources, particularly solar energy, by 2034/35. Additionally, Uganda has made strides in organic agriculture, becoming the 13th largest producer globally by 2003, with a 60% increase in organic farming areas and a 64% reduction in greenhouse gas emissions per hectare compared to conventional agriculture.

Moreover, the GE framework has spurred investments in new sectors such as green technology, green transportation, and green urban development in countries like China, India, Egypt, and Malaysia, resulting in the creation of green job opportunities, economic advancement, and reduced environmental damage, all while addressing climate change challenges. For instance, according to the German Development Institute's 2012 report and a UNEP report from 2014, initiatives in waste management are expected to generate an additional 24,000 jobs in Egypt, while sustainable agriculture could create 8 million jobs by 2050, alongside employment opportunities in recycling, composting, and biofuel production. In Bangladesh, around 3.5 million jobs were generated in eco-friendly sectors, with approximately 800,000 considered green jobs. Additionally, the solar photovoltaic sector created 3.37 million jobs globally in 2017, with Asia accounting for about 3 million, or 88%, of the total, predominantly in China.

In terms of poverty alleviation and social equity, GE policies in developing countries focus on supporting poor and vulnerable populations. For instance, reducing fuel subsidies can redirect funds towards public transportation and healthcare, enhancing the well-being of impoverished communities. Sustainable certification programs and eco-labeling initiatives in countries like Uganda, Nepal, and Egypt have generated new revenue streams from agricultural and forestry products. Furthermore, nations like China and Malaysia have implemented climate change adaptation and mitigation strategies that directly benefit disadvantaged groups.

However, defining the GE concept can be challenging due to its multidimensional nature and varying interpretations, particularly concerning its relationship with sustainable development in developing nations. This complexity leads to difficulties in identifying a singular theory that encompasses all factors influencing this relationship. Empirical evidence suggests that the impacts of GE on economic growth, employment, and poverty levels can vary among countries with similar economic and social conditions, depending on the specific economic policies and structural adjustments adopted during the transition. Consequently, each emerging country's unique social and economic context must be considered when assessing the effects of transitioning to a GE.

IV. Discussion

Aligned with the aspirations of a green economy, one of the primary objectives of sustainable development is to promote economic growth while preserving environmental quality. As a result, there has been extensive debate regarding the environmental implications of economic growth over recent decades, particularly in developing countries. Economic growth has become increasingly vital for nations to build their infrastructure in recent years. This relationship between environmental consequences and economic development presents a dilemma for both economists and environmentalists. Numerous studies have aimed to ascertain the causal link between economic growth and environmental degradation, yielding mixed outcomes. Some research indicates that economic growth negatively impacts environmental protection, suggesting that economic strength acts as a catalyst for environmental harm, particularly during the initial phases of development when economies are heavily reliant on fossil fuels and natural resources, as observed in the N11 nations, Bangladesh, the MENA region, leading African natural gas suppliers, Pakistan, Egypt, the USA and Europe, South Asia, and other developing countries.

Conversely, other studies propose that sustainable development is contingent upon green economic growth. Advancements in environmentally friendly and energy-efficient technologies, the dissemination of environmental knowledge and skills, the promotion of sustainable energy generation, and the diversification of the energy mix through increased use of renewable sources are all critical to fostering green economic growth, as highlighted in several case studies, G7 countries, Africa, the top 20 green innovator nations, and BIRCS. Given the development achievements of developing countries and their anticipated progress in the coming decades, these conclusions are particularly relevant. Thus, this investigation is aimed at addressing a significant research problem within the realm of developing economics.

The foremost goal of the 2030 Agenda for Sustainable Development is to eradicate poverty in all its forms. Target 1 of the Sustainable Development Goals emphasizes the need to eliminate poverty. Mobilizing substantial resources from various sources, including improved development cooperation, is essential to provide developing nations, especially the least developed, with the necessary means to implement programs and policies aimed at combating poverty comprehensively. The Sustainable Development Goals also strive to create effective policy frameworks at national and regional levels to ensure that by 2030, all individuals have equal rights to economic resources, including access to basic services, ownership and control over land and other properties, inheritance rights, natural resources, modern technologies, and financial services. Consequently, numerous scholars have sought to explore the critical role of the green economy in reducing poverty, yielding positive findings. Research indicates that the green economy enhances per capita income and reduces poverty ratios through mechanisms such as green financing, renewable energy utilization, and green hydrogen development.

The green economy has garnered significant scholarly attention due to its implications for employment. According to the United Nations Environment Program, a green economy fosters social equity and job creation, highlighting its positive impact on the labor market. The International Labor Organization supports this notion, asserting that the green economy has the potential to create millions of new jobs. Consequently, many studies have examined the relationship between the green economy and employment levels, exploring connections between environmentally-friendly innovations and job creation, as well as the association between green employment and the green economy's capacity to generate new investments, leading to favorable outcomes.

However, some research suggests that, despite the positive effects of a green economy on employment, there can also be negative impacts, particularly in developing nations. These studies argue that environmental protection may be perceived as a luxury that only developed countries can afford. These findings underscore the significance of this research endeavor in addressing a critical knowledge gap, especially concerning developing economies. The relationship between the green economy and employment levels, a crucial aspect of sustainable development, is particularly meaningful in our analysis, especially regarding its effects on developing countries.

There is a lack of publications in the academic sphere that examine how a green economy influences sustainable development through economic growth, poverty reduction, and employment levels in developing nations. Existing literature often focuses on a singular aspect of sustainable development, raising questions about whether the green economy can effectively accelerate the achievement of these goals. The findings from previous empirical studies indicate a scarcity of research on the drivers of sustainable development and insufficient evidence specifically related to developing nations. Given the critical importance of the green economy in these contexts, it is essential to evaluate these factors, providing recommendations to policymakers and formulating effective policies to reach sustainable development goals. Our theoretical framework and hypotheses, which build on the literature reviewed in this section, will be presented in the following section.

The positive coefficient of the Green Economy (GE) indicates that it contributes to economic progress, illustrating that green economic growth is essential for achieving sustainable development. This growth can stem from an increased reliance on environmentally friendly and cost-effective innovations, the promotion of sustainable energy production, and the diversification of the energy mix through greater adoption of renewable energy. This aligns with findings from previous studies.

It is important to note that among the four key dimensions of the Green Growth and Employment Index (GGEI), leadership and climate change, efficient sectors, and environmental and natural capital positively influence per capita income. The leadership and climate change dimension encompasses policies and regulations that assist developing countries in transitioning to a green economy without compromising their economic growth.

The efficient sectors dimension, which includes both public and private sectors such as energy, tourism, green transportation, and green building, is also significant for GDP per capita. These new green sectors contribute to boosting the country's economy and raising average per capita income. The positive impact of the green economy on employment can be attributed to various factors that promote social equity and create job opportunities, underscoring its beneficial influence on the labor market.

Additionally, regarding the environmental dimension of natural capital, it is logical that nations endowed with high-quality natural resources tend to exhibit advanced economic development levels, as these resources are vital inputs in the production function. Consequently, a favorable environment and rich natural capital are likely to enhance economic performance.

However, the relationship between the green economy and unemployment remains unclear, with findings indicating that only one aspect of the green economy has a significant positive impact on unemployment. The green economy influences job creation indirectly through economic output; thus, while productivity improvements can lead to increased employment and decreased unemployment, this secondary effect is limited and not solely driven by the green economy. These outcomes align with reports from the International Labour Organization, which suggest that the green economy has the potential to create millions of new jobs.

Furthermore, the promotion of the green economy aids in eradicating poverty, which contributes to sustainable development. This negative correlation exists because increased development cooperation provides the necessary and reliable resources to implement programs and policies aimed at alleviating poverty in all its forms. Numerous studies have concluded that the implementation of green economy strategies is essential for reducing poverty and advancing sustainable development.

Moreover, the green economy lowers poverty rates in countries based on their national criteria; thus, a higher environmental quality correlates with lower poverty levels. Among the key dimensions of the GGEI, two dimensions significantly affect poverty rates. First, the market and investment dimension shows a negative relationship with poverty levels. As green investment advances, per capita GDP and the standard of living in a country improve. This enhancement in economic standards leads to a decrease in the number of individuals living below the poverty line.

Second, the environmental and natural capital dimension also exhibits a negative correlation with poverty. The conservation of the environment and sustainable utilization of natural resources contribute to securing access to quality food and safe drinking water, thereby reducing malnutrition rates and directly lowering poverty levels in developing countries. Here's a rephrased version of your text while maintaining its original meaning:

The significance of the Green Economy (GE) concept arises not as an alternative to Sustainable Development (SD), but rather as a focused and direct approach and a vital tool for achieving SD. Transitioning towards a GE holds the potential for unprecedented economic growth and poverty alleviation, executed rapidly and effectively. This potential stems from two concurrent transformations. First, our society and the risks we encounter have dramatically changed due to evolving circumstances, necessitating a fundamental re-evaluation of our economic strategies. Second, there is growing acknowledgment that natural resources form the basis of our physical infrastructure and must be managed as a primary source of prosperity and well-being.

Consequently, countries are currently in a race to harness their available natural resources and renewable energy, particularly amid a global trend focusing on environmental issues to mitigate ecological degradation and biodiversity loss, alongside challenges such as acid rain and rising temperatures driven by greenhouse gas emissions that contribute to climate change with potentially catastrophic consequences. Therefore, GE can be viewed as a new economic paradigm and a critical element in economic development, job creation, and poverty reduction globally, especially in emerging nations.

In this context, the findings indicate that GE positively influences average per capita GDP and overall unemployment levels while negatively impacting poverty rates in developing countries. This suggests that the green economy is a key driver of sustainable development by fostering economic growth, creating new job opportunities, and reducing poverty in developing nations.

To emphasize the importance of a green economy, governments in developing countries should standardize its definition, measurement tools, and datasets used in calculations. Enhancing institutions and policies to encourage public and private sector investment in green sectors is essential, as is promoting scientific research and development initiatives and technological innovation. Allocating significant portions of public spending for research and development in the green economy, designing specialized programs to enhance labor quality through intensive training in advanced technologies for various green sectors, and improving workforce skills are critical steps.

Additionally, formulating and refining policies for transitioning to a GE that stimulate public spending and foreign direct investment is crucial for generating new economic sectors and investment opportunities, particularly to create job prospects for poor and vulnerable groups. Establishing a national green financial system that introduces new financial instruments such as green bonds, green insurance, and green credit is vital for meeting the sustainable financing needs for the green transition.

Moreover, promoting investments in renewable energy sectors, especially wind and solar energy, should be institutionalized across all sectors. Renewable energy products often lack institutional support, which may leave consumers unaware of their rights and responsibilities regarding these products. Therefore, relevant authorities and ministries must provide this institutional framework to enhance the adoption and expansion of renewable energy in developing countries.

Green policies should incorporate environmental, social, and economic factors to ensure equitable wealth distribution and equal opportunities for diverse population segments. Furthermore, it is important to encourage private sector investment in green sectors through economic incentives such as procurement policies, differential pricing, and tax benefits to promote renewable technologies and financing mechanisms. This includes encouraging the use of renewable energy technologies by reducing tariffs on equipment and components and eliminating or reducing fossil fuel subsidies.

This analysis focused on the connections between the green economy and sustainable development, particularly regarding the social and economic dimensions related to the first and eighth Sustainable Development Goals—namely, no poverty, decent work, and GDP—by examining emerging economies. For future studies, we recommend expanding the framework to incorporate additional sustainable development goals and including both developed and developing countries for comparative analysis to derive further insights.

Abstract

This paper investigates the significant role of human capital in driving economic growth, particularly in the face of pressing global challenges such as technological advancements, climate change, and rising economic inequality. The authors emphasize that human capital, defined as the collective skills, knowledge, and experience of individuals, is increasingly recognized as a critical factor in enhancing productivity and fostering innovation. The study begins by establishing a theoretical framework that links human capital to various models of economic growth, underscoring how investments in education, vocational training, and health can yield substantial economic benefits. The authors employ both quantitative data analysis and qualitative case studies to provide evidence that countries with higher levels of human capital tend to experience more robust economic growth trajectories. Key findings indicate that technological change necessitates a workforce that is not only skilled but also adaptable to rapidly evolving industry demands. The paper discusses how failure to invest in human capital can lead to skills mismatches and hinder economic competitiveness. Additionally, the authors explore the implications of climate change, asserting that a transition to a sustainable economy requires new skill sets in renewable energy, environmental management, and sustainable practices.

Keywords: human capital, economic growth, global challenges, technological change, climate change, economic inequality, education, vocational training

I. Introduction

In an era characterized by rapid technological advancements, increasing environmental concerns, and deepening economic inequalities, the role of human capital in driving economic growth has never been more critical. Human capital, encompassing the skills, knowledge, and health of individuals, serves as a pivotal resource that can significantly influence a nation's economic trajectory. As economies face unprecedented challenges such as automation, climate change, and global pandemics, understanding the interplay between human capital and economic growth becomes essential for policymakers, educators, and businesses alike.

Historically, economic theories have recognized the importance of physical capital and technology as key drivers of growth. However, recent studies underscore the growing recognition that human capital is equally, if not more, vital in enhancing productivity and fostering innovation. Countries that prioritize education, skills development, and health often demonstrate greater economic resilience and adaptability in the face of change. For instance, a well-educated and skilled workforce is better equipped to harness new technologies, adapt to shifting labor markets, and drive sustainable development initiatives.

Moreover, the global challenges of our time require a nuanced understanding of how human capital can mitigate their impacts. Technological change, while offering opportunities for growth, also poses risks of job displacement and widening inequality. Similarly, the effects of climate change demand a workforce capable of innovating and implementing sustainable practices. As such, the development of human capital emerges as a strategic priority for nations seeking to navigate these complexities effectively.

This paper aims to explore the intricate relationship between human capital and economic growth within the context of these global challenges. It will examine how investments in education and health can serve as catalysts for economic development while addressing the disparities that hinder progress. By analyzing both theoretical frameworks and empirical evidence, the study will highlight the critical need for comprehensive policies that promote human capital development as a means to achieve sustainable and inclusive economic growth.

As we embark on this exploration, it is imperative to consider not only the economic implications but also the social and ethical dimensions of human capital development. In doing so, we can better understand how to leverage human potential to build resilient economies capable of thriving amid uncertainty.

II. Methods

1. Econometric Modeling

This method involves using statistical techniques to analyze the relationship between human capital indicators (such as education and health metrics) and economic growth rates. Data will be sourced from international databases like the World Bank and OECD. Multiple regression analysis will be employed to quantify the impact of human capital on GDP growth while controlling for factors such as physical capital investment and technological advancement.

2. Comparative Case Studies

This qualitative method focuses on in-depth analyses of specific countries or regions that have successfully utilized human capital to drive economic growth. Countries will be selected based on diverse economic contexts and effective human capital policies. Each case study will evaluate key interventions—such as education and training programs—and their impact on economic outcomes, using both quantitative indicators and qualitative assessments.

3. Surveys and Interviews

This method involves gathering primary data through surveys and semi-structured interviews with key stakeholders, including policymakers, educators, and business leaders. Surveys will assess perceptions and experiences related to human capital development, while interviews will provide deeper insights into the effectiveness of current policies and practices. The collected qualitative data will be analyzed thematically to identify trends and best practices in human capital investment.

III. Results

Education and skill disparities likely account for some of the differences observed between countries. Researchers have found evidence indicating a correlation between educational attainment and individual GDP. In less developed nations, educational levels tend to be low due to economic struggles, creating a cycle where limited education further hinders economic growth. Hall and Jones (1999) suggest that we can incorporate metrics of education and training to evaluate the extent of human capital, allowing for comparisons of human capital development across various countries. Since 1990, the United Nations Development Programme (UNDP) has collected and presented data on the Human Development Index (HDI), which integrates three fundamental dimensions of human development: life expectancy at birth, which indicates overall health and longevity; years of education and expected years of schooling, which reflect knowledge and learning; and gross national income per capita, which assesses the ability to maintain a sustainable standard of living. The HDI scale ranges from 0 to 1, where 0 signifies the lowest level of human development and 1 signifies the highest. Table 1 below displays the HDI values for selected developed, developing, and least developed countries.

Table 1: *Human Development Index in developed, developing and less developing countries*

Countries	1990	1995	2000	2005	2010	2015	2016	2017
Bangladesh	0.387	0.425	0.468	0.505	0.545	0.592	0.597	0.608
China	0.502	0.55	0.594	0.647	0.706	0.743	0.748	0.752
India	0.427	0.46	0.493	0.535	0.581	0.627	0.636	0.64
Japan	0.816	0.84	0.855	0.873	0.885	0.905	0.907	0.909
Malaysia	0.643	0.683	0.725	0.821	0.729	0.772	0.799	0.802
Pakistan	0.404	0.428	0.45	0.5	0.526	0.551	0.56	0.562
Singapore	0.718	0.773	0.819	0.868	0.909	0.929	0.93	0.932
South Korea	0.728	0.778	0.817	0.855	0.884	0.898	0.9	0.903
Turkey	0.579	0.607	0.655	0.69	0.734	0.783	0.787	0.791

Individuals play a crucial role in driving economic performance and progress (Schultz, 1961). The quality of social assets relies on the premise that a skilled and productive workforce can operate more efficiently, contribute economically, and engage in more productive activities, thereby fostering economic advancement (Baldacci et al., 2008). Various inclusive growth strategies have proven to be more effective than others and are essential for improving the economic conditions in developed nations. Data indicates that Singapore's growth and asset development surpass those of many developed countries, with its economy thriving due to significant human capital investment.

The apparent benefits of neoliberal globalization have heightened the interest of developing countries, as this perspective emphasizes the connection between markets, competitiveness, economic efficiency, and consumer choice. Consequently, these economic sectors necessitate human capital. Training the workforce in emerging economies to meet the increasing demands for poverty alleviation, enhanced employability, productivity, and global competitiveness has become a national priority in skill development and training initiatives to promote growth. Notably, China and Turkey have achieved impressive results in their Human Development Index (HDI), while Malaysia is also making strides in human capital development. This focus on human investment is a key reason why the developing world is attaining greater economic stability.

IV. Discussion

Global competitiveness can only be achieved through collaborative efforts among countries worldwide, working together to reach their goals in line with evolving technologies and advancements. The World Economic Forum publishes the Global Competitiveness Report, which tracks the ongoing factors and institutions vital for sustainable growth and competitiveness, enabling countries to be assessed and calibrated to maintain their competitive edge.

The Global Competitiveness Index (GCI) serves as a composite measure consisting of twelve components, grouped into three overarching categories. The first category, fundamental requirements, encompasses institutions, infrastructure, the macroeconomic environment, health, and basic education. The second category, efficiency enhancers, focuses on higher education and training, product market efficiency, labor market efficiency, financial market development, technological capabilities, and market size. Finally, the third category includes elements related to business sophistication and innovation.

The GCI is rated on a scale from 1 to 7, where 1 represents the lowest score and 7 signifies the highest. Table 2 below presents the GCI values for selected developed, developing, and least developed countries.

Table 2: *Global Competitiveness Index in developed, developing and less developing countries*

countries	2013	2014	2015	2016	2017
Bangladesh	3.547942	4.835891	4.736538	4.698532	4.565805
China	4.897789	4.835891	4.736538	4.698532	4.565805
India	4.304978	4.328038	4.303131	4.326408	4.33399
Japan	5.396211	5.36931	5.369902	5.375314	5.426291
Malaysia	5.084289	4.883098	4.873699	5.044747	5.097477
Pakistan	3.578805	3.483689	3.581879	3.652812	3.770316
Singapore	5.625705	5.477664	5.545332	5.534784	5.447093
South Korea	5.02079	4.930196	5.003964	5.275884	5.396472
Turkey	4.280638	4.24749	4.160859	4.148129	4.246872

Human capital is intricately linked to economic and industrial advancement. Therefore, understanding their relationship is essential for enhancing productivity and capabilities, leading to competitive advantages and surplus value that can drive technological progress and diversify economic activities, ultimately fostering economic growth. As a result, the development of human capital has become vital for achieving growth. Many researchers agree that government investment in health and education to strengthen human capital has a positive and significant impact on the economy.

Human capital is represented by a nation's skilled and capable workforce. It is routinely assessed and can be enhanced through both formal and informal education or training. Importantly, human capital is not confined to traditional schooling; it also includes on-the-job training and non-traditional technical programs that enhance skills. Kazmi et al. (2017) analyzed both formal and informal education, along with various socioeconomic factors such as school enrollment, life expectancy, health, knowledge, and skills, using time series data from 1992 to 2024. Their study underscores the significance of human capital as an intangible resource collaboratively managed by individuals and organizations within a community.

The evidence indicating a relationship between human resources and development is compelling. Furthermore, human capital is essential in empirical studies that explore the factors influencing economic advancement. While many researchers argue that human capital has a positive and substantial effect on economic growth, empirical findings have yielded mixed results. Theoretical literature often addresses the measurement of human capital. The research explored the strong correlation between human capital and economic recovery using the Johansen multivariate cointegration test and Granger causality test.

Economic growth is essential for determining a country's position on the Global Competitiveness Index (GCI). It enhances productivity, fosters innovation, supports infrastructure development, and encourages investment in human capital, all of which are critical for competitiveness. Expanding economies attract investment, broaden their global reach, and demonstrate resilience in the face of challenges. Ultimately, sustained economic growth serves as a fundamental driver of success on the GCI, as it underpins various factors that enhance a nation's competitiveness and global prosperity.

Furthermore, an economy that evaluates its workforce size, physical capital, human capital, and technological capabilities can better understand its production capacity. When comparing two countries, the one with greater physical capital, a larger labor force, a more educated and skilled workforce, and superior technology will likely produce more and achieve a higher ranking on the GCI. This study highlights the crucial role of human capital in driving economic growth. Human capital encompasses the knowledge, skills, education, and health of a nation's workforce, emphasizing that investing in and developing human capital is vital for maximizing economic growth and securing a favorable position on the GCI.

Consequently, it is essential to prioritize key inputs such as human capital and economic growth to achieve the desired outcomes in global competitiveness across various economies. Additionally, the study employs statistical tools, particularly classical techniques, to support its findings and analysis. This approach indicates that the research utilizes established statistical methodologies to examine data and draw conclusions about the relationships between economic growth, human capital, and competitiveness. For effective policy formulation, it is also crucial to employ a diverse array of statistical tools in data analysis to optimize modeling.

DYNAMIC MODELLING AND MULTIPHASE FLOW OPTIMISATION – GARANTEUR OF SAFE AND SECURE HYDROCARBON PRODUCTION

Rufat Mangushev, Gafar Ismayilov
•
Azerbaijan State Oil and Industry University
rufat.mangushev@gmail.com
asi_zum@mail.ru

Abstract

These days petroleum and condensate formations, especially offshore ones, are actively being developed. The main feature of such formations is multiphase flow in tubing and riser. During production flow liquid slugs, adverse pressure pulses, and often hitting impacts are detected as a result of high gas content, interphase tension forces and complicated pipeline geometry, leading to pressure surges. The energy and very functioning efficiency of both gaslift and fountain operated wells is thus drastically reduced with the disturbance of the optimal production regime. In this paper it has been determined that a novel approach to multiphase flow management allows for decrease in emergency failures and operational expenses. Thus, right modelling and optimization of phase slippages can become a good guaranteur of safe and secure well operations.

Keywords: optimization, multiphase, TPR, flux, dynamic pressure

I. Introduction

Multiphase systems (liquid-gas, liquid-solid particles, etc.) periodically exert significant dynamic pressures on production facilities, such as tubings, gathering pipelines, flare jackets, compressor inlets, separators, pipelines transporting unrefined gas from site to the refinery, etc. There are facts of discard of sucking collectors of vacuum gas lift compressor stations, flare pumping units, support piles kinks at "earth-air" split under the pipelines, catastrophic riser failures, etc. As a rule of thumb, dynamic loads arise at pipeline turns when density of the transported multiphase medium is subject to swift and significant changes.

Pipeline location affects the inner liquid flow characteristics including pressure changes, speeds, and phase concentrations. This is an interesting and multifaceted modern pipeline construction and operation challenge, especially relevant for multiphase well liquids gathering and transportation pipelines [1]. Complicated geometry of manifolds, well piping and underwater equipment of offshore petroleum production systems is in it of itself a configuration matrix, each element of which is capable of drastically changing not only direction but also type and characteristics of the multiphase flow.

II. Methods

It is known that multiphase flow regime boundaries are under visible influence of each individual phase's speed, density, viscosity, flow direction, physical and chemical properties, as well as pipeline geometry, and many other parameters.

According to [2] bubble regime borders in vertical pipe lie between gas speed of 1 to 10 m/s and liquid speed up to 2 m/s. Diameter increase of more than 10 sm leads to widening of the with probable bubble regime zone: gas speed boundaries are 0,1 to 10 m/s and remain roughly the same for liquid speed. When one zone boundaries move, the respective changes happen in boundaries of slug flow, churn flow, annular flow, and mist flow – i.e. all types of multiphase flow.

Problems of formation of a "severe" slug flow or pulsing flow that manifest in subsurface pipelines (gaslift pipelines) of various geometries are discussed in detail in [3, 4].

When considering multiphase flow dynamics, it is vital to clearly understand that flow structure may change with changes in flow rates. Dispersed structure forms at higher mixture flow rates, when its speed exceeds critical, during which structural changes manifest.

In this case the components mixture is a homogenous structure characterized by constant density across all of the flow's volume. If the flux is maximal, speed of the mixture is below critical, thus gradient-speed field tension [5, 6] of the flow is not sufficient for the homogenous mixture to form. The flow consists of alternating gas and liquid slugs. Flow components are divided by a phase boundary.

Flow regime also characterizes its layered structure. Unbalanced dynamic loads appear at turns of the pipelines during slug flow. To determine the maximal value of these dynamic forces affecting multiphase pipeline, it is vital to determine critical mixture speed value at which structure changes evolve. To determine this speed the following equation is used:

$$v = 1.26\sqrt{g(\rho_l - \rho_g)D/\rho_g} \quad 1)$$

Where, ρ_l, ρ_g – respectively liquid and gas density kg/m^3
D – pipeline diameter, m;
g – gravitational acceleration, m/s^2

The force acting on the pipeline with change of mixture density is defined as multiplication of residual of dynamic pressures by cross-sectional area of the pipeline.

$$F = (\rho_l - \rho_g)v^2\pi D^2/4 \quad (2)$$

Considering features of multiphase flow in vertical pipelines and as a result of analysis of different models it is possible to diagnose optimal operational zone of a multiphase gaslift which corresponds to enhanced energy efficiency of hydrocarbon production. Having that in mind as a result of gaslift well testing in coordinates liquid flow rate (Q_l), gas flow rate (Q_r) and at constant pressure drop performance relationship curves are built (Fig. 1).

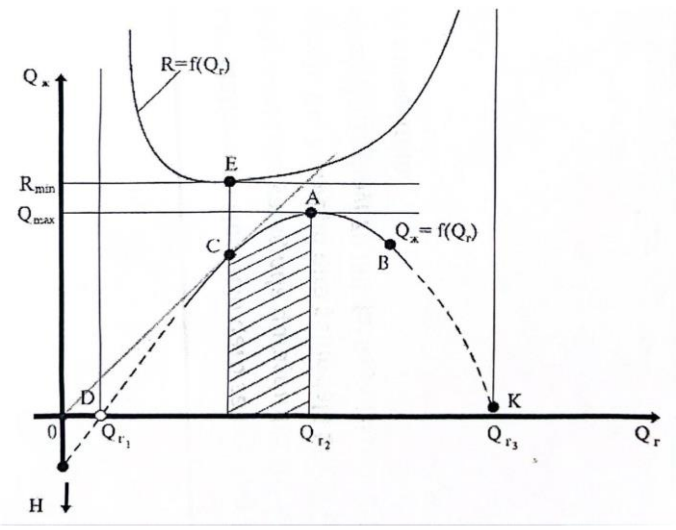

Figure 1: *Gaslift working regime performance relationships*

The following points of interest can be observed on the curve:
- Point D – flow initiation;
- Point A – maximal flow;

- Point K – flow termination.

III. Results

In order to increase efficiency and safety of the gaslift or fountain wells performance relationship curves in coordinates $Q_l = f(Q_g)$ are tied to TPR of the gaslift well that is constructed in coordinates pressure drop (ΔP) vs gas flow Q_g at various liquid flow rates (Fig. 2). In this figure zero liquid flow rate ($Q_l = 0$) corresponds to sparging.

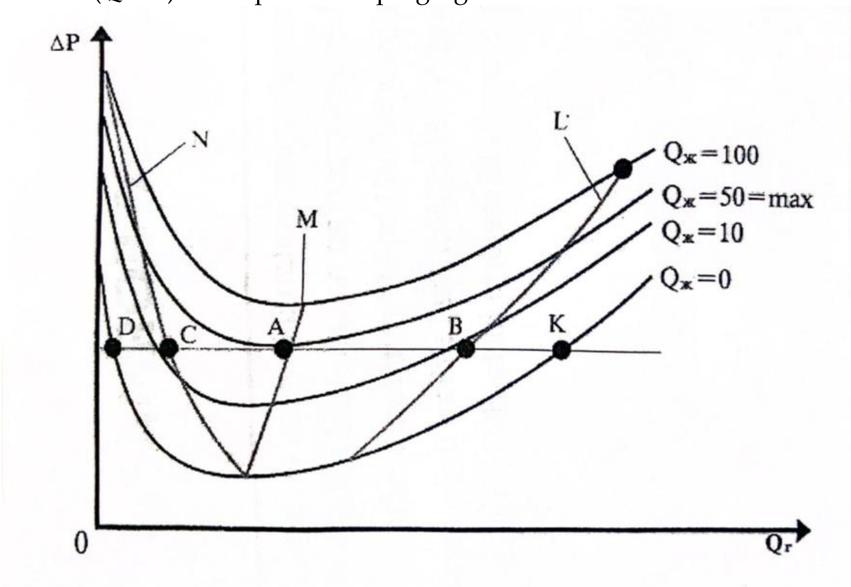

Figure 2: *Multiphase well TPR at constant liquid flow rates*

Should we draw a constant pressure drop line on the TPR curve, three characteristic points D, A and K ae obtained, as on performance relationship curve. Points D and K cross the line of zero liquid flow rate, point A is tangential to the maximal flow rate curve in minimal pressure drop regime. Line N corresponds to minimal specific gas flow rate R_{min}, line M – to minimal pressure drop, P_{min} and line L to minimal specific pressure drop. Zone between lines N and M corresponds to optimal work regime from minimal pressure drop to minimal specific energy expenditure.

Inflow and tubing performance relationship are also important elements of well performance prognosis. Inflow and tubing performance relationship curves intersection point prognoses the future well performance (Fig. 3).

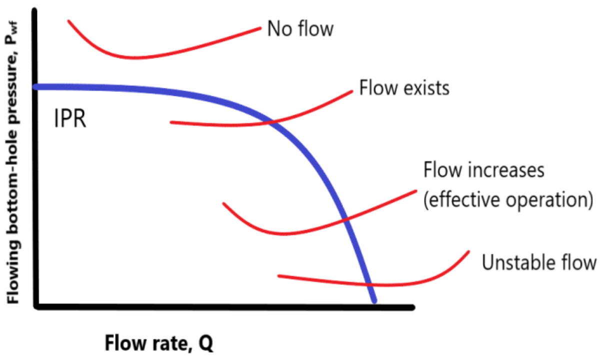

Figure 3: *Modes of TPR crossing IPR*

Fig. 3 represents different TPRs and their correlation modes with IPR. It is apparent that the TPR must intersect the IPR to the right of the extremum of the multiphase TPR otherwise well should be considered unstable.

IV. Discussion

Determination of direction and numerical value of dynamic loads in multiphase pipelines is paramount with regard to safety of transportation. A mathematical model has been proposed to determine these loads considering critical speed and structural changes in multiphase flows.

It has been demonstrated, that to increase safety and efficiency of the gaslift operations performance relationship curves in coordinates $Q_l = f(Q_g)$ must be tied to gaslift TPR curve at various liquid flow rates.

Multiphase flow features must be carefully considered when designing the most economically sound and technologically safe flow diagram.

[2]Ganja State University, AZERBAIJAN
samira.akbarova@azmiu.edu.az
reyhan.akbarli@azmiu.edu.az

Abstract

The significant potential of renewable energy sources (RES) in Azerbaijan served as the basis for the green energy transition (GET) and the integration of renewable energy into the country's energy supply system. A bibliometric analysis of trending scientific research issues on the technological aspects of GET was carried out using the metadata of publications indexed in the Web of Science (WoS) Core Collection abstract database over the past 4 years using the VOSviewer program. As a result of the analysis, four main directions of scientific research were identified: optimization of energy resource consumption; the impact of renewable energy sources on sustainable development; the environmental benefits of the energy transition; and technological innovation. The publications of the first cluster mainly address the problems of optimizing energy generation from renewable sources, primarily solar and wind energy, as well as issues of storage, distribution, and energy consumption. The second cluster presents an empirical analysis of the impact of renewable energy consumption on carbon dioxide emissions and, as a consequence, on environmental sustainability, considering energy consumption and cointegration. In the works of the third cluster, environmental sustainability is assessed as a key priority of modern energy policy in light of the need for an energy transition from traditional energy to the use of renewable energy sources and the fight against climate change. Research in the fourth cluster reflects the benefits of using floating solar power plants. The results can serve as a basis for developing efficient government strategies for GET.

Keywords: green energy transition, renewable energy, VOSviewer program

I. Introduction

The modern global energy system is undergoing a socio-technical transformation called the "energy transition" or "green energy transition" (GET), which involves the use of renewable energy sources (RES) to replace fossil fuels and nuclear energy [1]. The GET has two goals: expanding sources of RES, increasing the share of their use, and reducing greenhouse gas emissions [2]. Globally, consumers spent nearly 20% more on energy in 2022 than the previous five-year average [3]. Almost one in ten people out of 40 million in the European Union could not provide sufficient heat in their homes [4, 5]. Therefore, energy transition issues are the center of attention for the world community. The most common and used renewable energy sources are hydropower, solar, wind, bioenergy, geothermal, and tidal. According to the International Energy Agency (IEA), for 2023, the share of energy production from renewable energy sources in countries that are members of the agency was 30.2% [6]. As follows from Fig. 1, the share of solar and wind energy capacity is increasing, while hydropower is decreasing. According to IEA forecasts, the commissioning of green energy capacity will steadily increase and should reach more than 40% by 2030 [7]. For Azerbaijan, the share of RES in the country's energy balance is 18%. By 2030, it is planned to increase this figure to 30%, by 2050, it will be more than 40% [8].

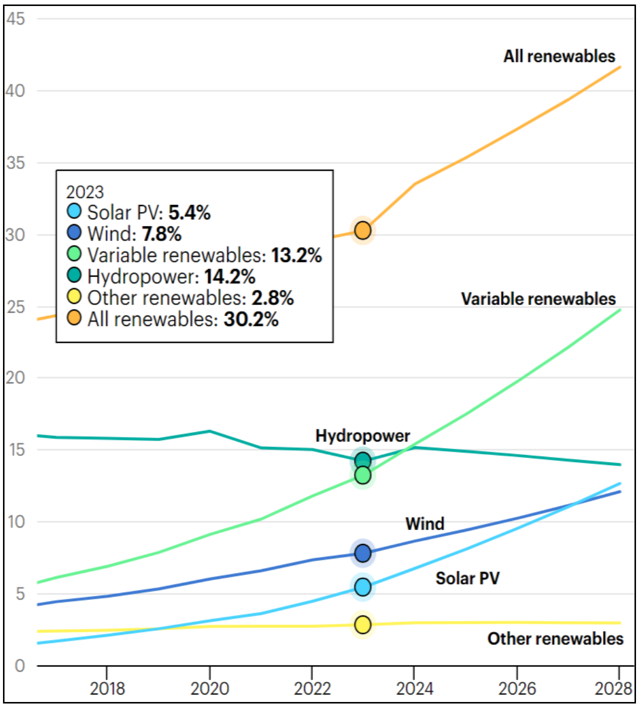

Figure 1*: Renewable electricity generation by segment*
(https://www.iea.org/reports/renewables-2024/executive-summary)

For a long time, in the development of the national economy of Azerbaijan, the main driver of growth was the extraction and export of fossil energy resources, which led to risks of environmental degradation and imbalance of the ecosystem. The year 2024 in Azerbaijan was declared the "Year of Solidarity for the Green World" (https://azertag.az/ru/xeber/azerbaidzhan_lider_v_regione_po_perehodu_na_zelenuyu__energiyu_2882779), which involves the introduction of green energy technologies, environmentally friendly waste processing, the introduction of environmentally friendly production with zero greenhouse gas emissions, and the implementation of measures to restore contaminated areas [9, 10]. The significant potential of Azerbaijan's renewable energy sources served as the basis for their successful integration into the country's energy supply system: the technical potential of green energy (GE) on land is 135 GW, and on the shelf of the Caspian Sea,- 157 GW [11]. Since 2021, the Karabakh region of the country has been declared a "Green Energy Zone," and corresponding creative work is underway. The region's energy supply is planned to be fully provided by green energy [12]. In international projects on green energy and the energy transition implementation, Azerbaijan works with Norway, Great Britain, the United Arab Emirates, and Slovakia [13]. The scale of Azerbaijan's development in GET makes it relevant to study promising scientific research and international experience in using green energy.

The purpose is to identify trending research tasks on the technological aspects of countries' transition to green energy, analyze foreign experience in introducing various types of green energy, and forecast potential areas for green energy development.

II. Methods

To study the scientific field of GET, this study applies the publication analysis methodology by using keywords for scientific articles in the WoS database [14,15]. Keywords are a mandatory and important informative component of each article [16,17]. If the author does not give the keywords, they are assigned by the WoS database. To analyze the topic of GET and determine the main trends in scientific research, the tools of the VOSviewer 1.6.20 program were used. The keywords used in the search were: green technologies, renewable energy, alternative energy, low-carbon energy, environmentally friendly energy, sustainable energy, technology, sustainable energy transition, low-carbon transition, transition to renewable energy sources, and decarbonization. The initial query to the WoS database was carried out on May 16, 2024, and 7244 scientific publications were identified for 2021–2024. To narrow the scope of research, scientific articles from the WoS Categories section were selected from this number, and the section "Green sustainable scientific technologies" was selected (Table 1). The remaining 894 publications are downloaded from the WoS database as a tab-delimited file in Full Record format. Next, in the VOSviewer program, select the data type: - Creating a map using bibliographic data. The program then reads data from the downloaded WoS files. As a type of analysis of keywords, their co-presence in publications is selected, and the calculation method is complete (Table 2).

Table 1: *Data collection process [18,19]*

III. Results and discussion

Energy transition means the transition from energy systems based on fossil fuels, such as oil, natural gas, and coal, to systems based on renewable energy sources, such as solar energy, wind, and biofuels. Azerbaijan's policy shift towards renewable energy sources was accelerated after 2020 with the return of 20% of its territory. In 2023, during COP-28, President I. Aliyev formulated strategies for the country's energy transition, promoting carbon neutrality. Therefore, there is an urgent need for large-scale research to increase the use of cleaner energy sources. This bibliometric review analyzes research on the technical aspects of countries' energy transitions over the past four years and identifies future promising research [21, 22]. By mapping the keywords of scientific publications on the energy transition, this study uses bibliometric software such as VOSviewer to display the research results of scientific publications listed on the Web of Science in 2021-2024. Analysis of research shows that aspects such as climate change, alternative energy, green energy management approaches, and emissions reduction are becoming increasingly important. Additionally, areas requiring future research include the development of policy frameworks, energy infrastructure (storage and transmission), renewable energy ecosystems, GE adaptation, economic analysis of clean energy, and impact assessments for a timely energy transition around the world [23, 24]. Therefore, cooperation between countries and research institutions should be promoted, with a special focus on the development of clean technologies and knowledge transfer for a rapid energy transition around the world.

From the metadata of the downloaded 894 publications, the VOSviewer program identified 4981 keywords. With a minimum number of co-present keywords of 11, 107 words were involved in constructing the map. Of these, the 20 most frequently used keywords with co-presence frequency and full degree of connections are shown in Fig. 2, these are mainly the terms and phrases of the authors themselves.

Figure 2: *20 top keywords*

In the 894 publications reviewed, the most frequently used terms were renewable energy, carbon dioxide emissions, impact, energy consumption, economic growth, optimization, productivity, sustainability, generation, management, system, power, China, energy transition, etc.

The 107 words selected by the program are grouped into 4 clusters and indicated in different colors (Fig. 3):

1st cluster - red - 37 terms on optimization of energy resources;

2nd cluster - green - 33 terms on renewable energy sources and sustainable development;

3rd cluster - blue - 30 terms on environmental benefits of the energy transition;

4th cluster - yellow - 7 terms on technological innovations.

The publications of the first cluster mainly address the problems of optimizing the generation of energy from renewable sources, mainly focusing on solar and wind energy, as well as issues of energy storage and distribution [25]. In [6], the energy sector is presented as the core of the global goal of reducing carbon dioxide emissions, and renewable energy sources are becoming an increasingly preferred source of energy generation throughout the world, and their use leads to decarbonization of the energy sector.

According to the publication, generated in the second cluster, the energy transition to the predominant use of green energy is an integral component of the strategy of states on the path to sustainable development. The publications provide an empirical analysis of the impact of renewable energy consumption on carbon dioxide emissions and, as a consequence, on environmental sustainability, considering energy consumption and cointegration. The articles [16] examine the relationship between renewable energy consumption and economic growth using the concept of the environmental Kuznets curve. Based on the analysis of empirical data, strategies are proposed for an effective energy transition aimed at reducing greenhouse gas emissions and promoting environmental sustainability (Fig. 4).

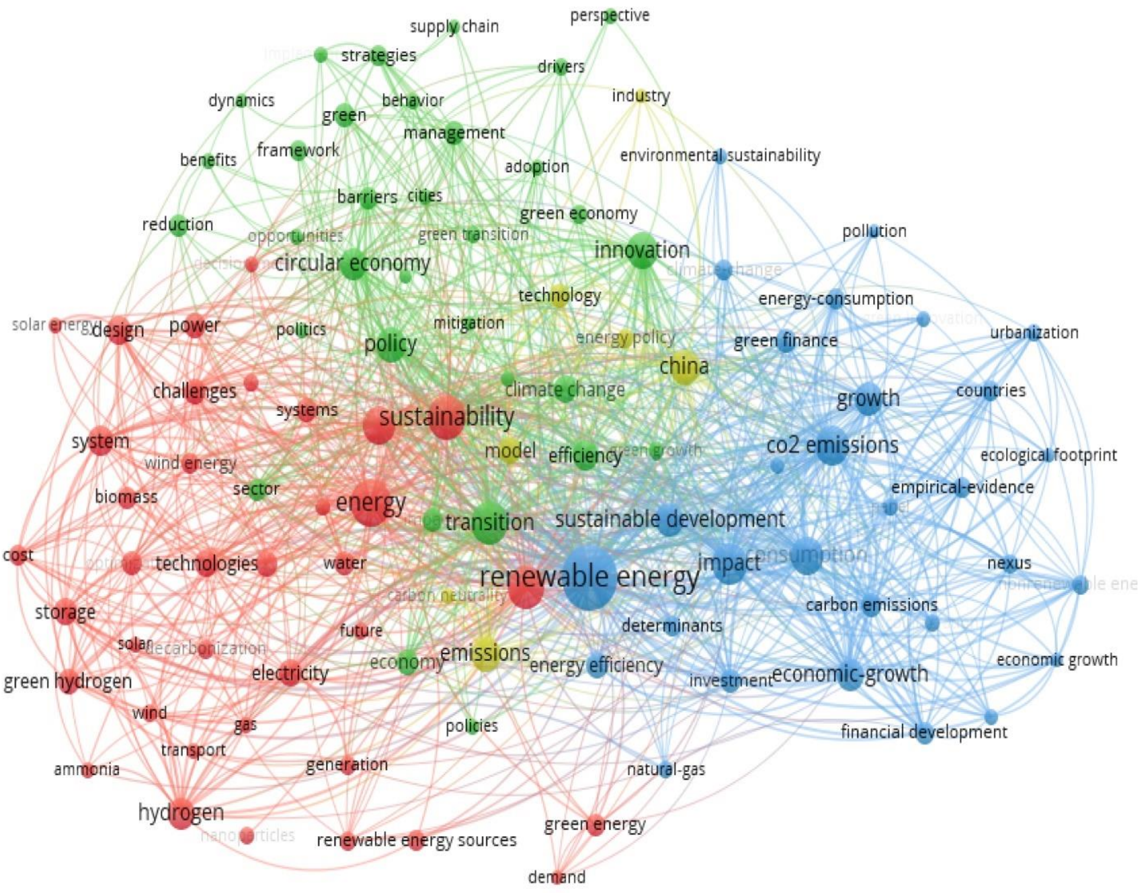

Figure 3: *Clustering of co-occurrence of all keywords (Author KW + KW Plus)*

In the works of the third cluster, environmental sustainability is assessed as a key priority of modern energy policy in light of the need for an energy transition from traditional energy to the use of renewable energy sources and the fight against climate change [1]. Article [26] analyzes the factors influencing the achievement of carbon neutrality, based on the concepts of energy efficiency and the use of innovative technologies. [9] examines the role of public energy policy in promoting environmental sustainability and achieving the energy transition. Based on an analysis of current trends and best practices, recommendations are offered for the development of strategies aimed at promoting sustainable development and reducing negative impacts on the environment. The environmental disadvantages of green energy are studied in [24]:

-for hydroelectric power plants (HPP)- flooding of territories during construction; construction is only possible nearby rivers and large reservoirs; not suitable for construction in northern regions; changes in the microclimate around hydroelectric power stations lead to changes in flora and fauna, changes in river beds and, as a consequence, ecosystem body of water;

-for solar power plants- environmental pollution is observed during the extraction of the main element for the production of solar panels - silicon; environmental pollution occurs during the disposal of solar panels and batteries due to the high cost of processing elements;

-for wind power plants- environmental pollution during the disposal of wind generator blades; high-noise wind generators; low-frequency vibrations cause soil corrosion.

The publications in the fourth cluster discuss Floating Solar Power Plants (FSPPs). The energy efficiency of FSPP is up to 10 % higher than ground-based ones. FSPP can occupy unused space in water bodies, including reservoirs at hydroelectric dams, other than those intended for drinking water supply. FSPP often requires fewer materials than a similarly sized above-ground project, less maintenance, and less cleanup since the panels are typically located away from potential sources of debris.

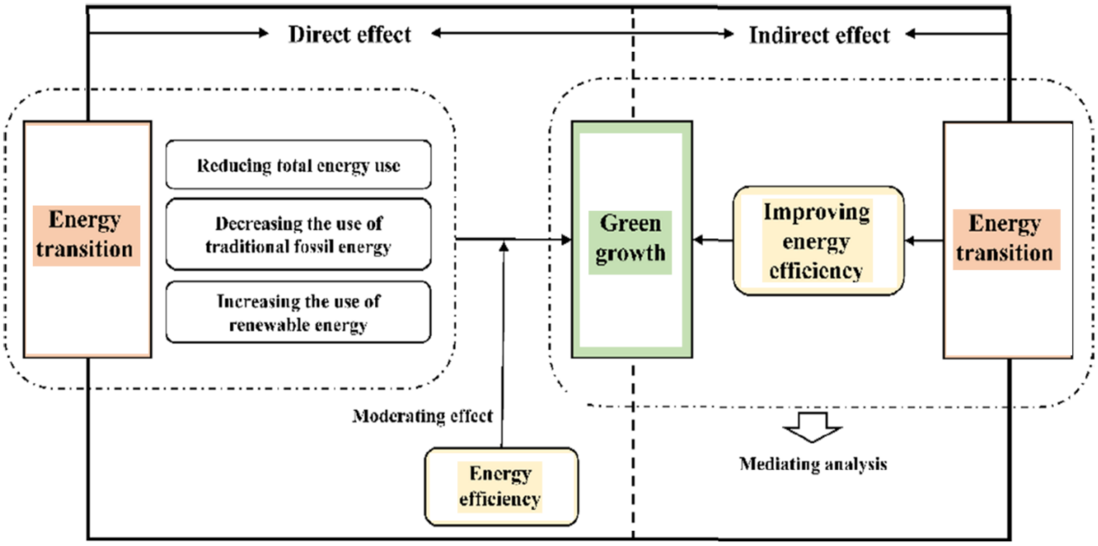

Figure 4: *The theoretical link between energy transition and sustainable development [6]*

IV. Conclusion

The "green" energy transition is a global economic policy trend that entails the need for a radical restructuring of many industries, primarily energy, construction, and transport, to achieve carbon neutrality. The study of the scientific field of "energy transition" in the context of modern global energy policy is a topical issue, the focus of which is the replacement of traditional energy resources with renewable energy sources. An analysis of 894 scientific publications selected by the

VOSviewer program using metadata analysis methodology revealed the main trends and prospects for this scientific area of research (Fig. 5): this is primarily a solution to the problems of optimal sustainable energy consumption. The results obtained indicate significant interest in the optimization of energy resources, the development of renewable energy, and sustainable environmental development [25]. Four key clusters have been identified, which examine aspects of the optimization of energy resources, the use of renewable energy sources, and their impact on the environment. This study highlights the importance of the transition to sustainable energy sources, in the context of combating climate change and achieving environmental sustainability. The results, based on the analysis of current trends and practices, can serve as the basis for the development of effective government strategies and programs aimed at achieving sustainable development and reducing the negative impact on the environment in the energy sector [26].

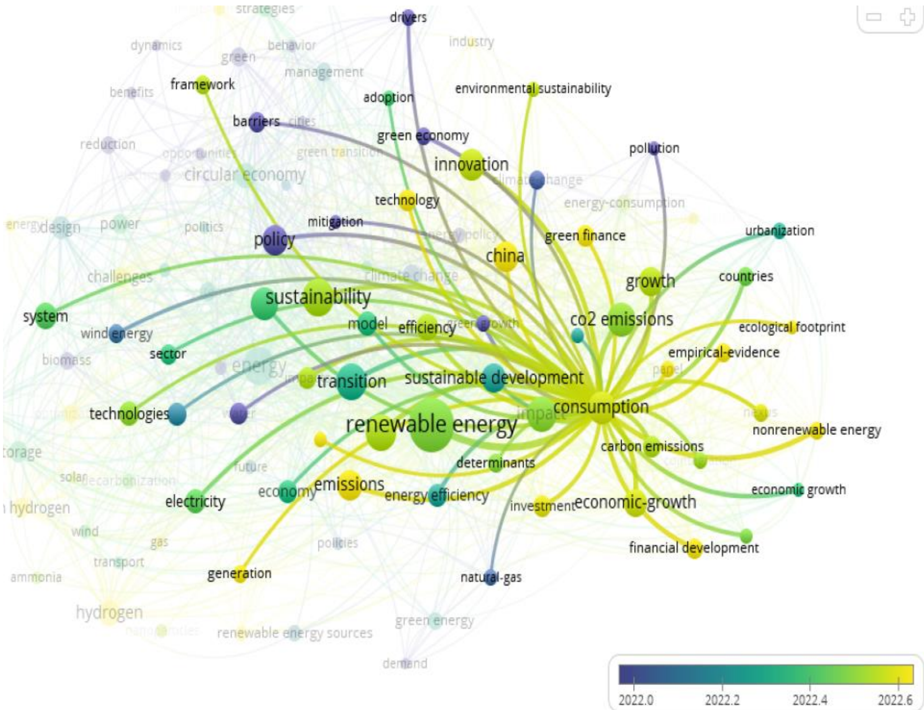

Figure 5: *Emerging research topics*

In Azerbaijan, renewable energy generation is at the beginning of its development. To achieve the results planned by 2030, not only government support is required, but also the formation and development of the entire production chain- from research and development to the creation of our industry for the production of equipment for renewable energy sources. Because the renewable energy sector is one of the most innovative, its development will be quite significant for the country's economy, both in terms of the creation of new high-tech products and in terms of the creation of new high-tech industries.

THE ROLE OF THE ENVIRONMENT IN SHAPING THE LIVING CONDITIONS OF DEPORTED PEOPLES

Sapiyat Tsutsulaeva

•

Kadyrov Chechen State University, RUSSIA
sapiyat_univ@mail.ru

Abstract

This study examines the significant role that environmental factors play in shaping the living conditions of deported peoples throughout history. The experiences of deported individuals are often profoundly influenced by their new environments, which can affect their health, economic opportunities, and social integration. The research explores various case studies of deported populations, analyzing how different environmental conditions—such as climate, geography, and access to resources—impact their day-to-day lives. The findings indicate that deportees often face harsh living conditions that are exacerbated by environmental challenges, including extreme weather, inadequate housing, and limited access to clean water and food. These environmental stressors can lead to significant health issues and hinder the ability of deported peoples to rebuild their lives in new locations. Furthermore, the study highlights the importance of understanding the interplay between environmental factors and the social, political, and economic contexts in which deported peoples find themselves. The research suggests that policymakers must consider environmental conditions when developing support systems for deported populations, ensuring that interventions are context-specific and sensitive to the unique challenges posed by their environments. Ultimately, this study contributes to a deeper understanding of the complexities surrounding deported peoples and emphasizes the need for an integrated approach that addresses both environmental and socio-economic factors to improve their living conditions and promote their well-being. In conclusion, the role of the environment in shaping the living conditions of deported peoples during and after the Great Patriotic War was significant and multifaceted. The interplay between climatic conditions, health implications, cultural adaptation, and economic challenges not only affected their immediate survival but also influenced their long-term socio-economic conditions and cultural identity. Understanding these dynamics is crucial for recognizing the resilience and adaptability of deported communities in the face of overwhelming challenges. This analysis underscores the importance of environmental context in the broader narrative of displacement and survival, contributing to a more nuanced understanding of the historical experiences of deported peoples. Further research in this area can provide valuable insights into the ongoing issues faced by displaced populations today, fostering a deeper appreciation for their resilience and the factors that contribute to their well-being. In conclusion, the experience of deported Chechens during and after the Great Patriotic War exemplifies the profound role of the environment in shaping their living conditions. Understanding this relationship is essential for developing policies and practices that support the resilience and adaptation of displaced communities. As we reflect on the past, it is crucial to consider how we can create better conditions for future generations, ensuring that our approach to environmental and social challenges is informed by the lessons learned from history.

Keywords: environment, deportation, living conditions, adaptation, agricultural practices, climatic conditions, cultural identity, socio-economic challenges, resilience

I. Introduction

The phenomenon of forced deportation has shaped the lives and experiences of countless individuals and communities throughout history. Whether as a result of political persecution, war, or ethnic cleansing, deported peoples often find themselves in unfamiliar environments that significantly influence their ability to adapt, survive, and thrive. Understanding the role of the environment in shaping the living conditions of these populations is crucial for developing effective support systems and policies aimed at improving their well-being.

Environmental factors encompass a range of elements, including geographical characteristics, climate conditions, access to natural resources, and the availability of infrastructure. These factors can profoundly impact the quality of life for deported peoples, influencing their health, economic opportunities, and social integration into host communities. For instance, extreme weather conditions can exacerbate health risks, while limited access to arable land or clean water can hinder economic self-sufficiency.

This study aims to explore the multifaceted relationship between environment and the living conditions of deported peoples. By analyzing historical and contemporary case studies, this research seeks to illustrate how environmental challenges shape the experiences of deportees and inform their capacity to adapt to new settings. The focus will be on several key aspects:

1. Geographical Impact: Different geographical contexts can present unique challenges and opportunities for deported populations. For example, those relocated to urban settings may experience different challenges than those sent to rural areas, influencing their ability to find employment and access essential services.
2. Climate Considerations: Climate conditions can significantly affect the health and livelihoods of deported peoples. In regions prone to natural disasters or extreme weather, deported individuals may face additional vulnerabilities that exacerbate existing challenges related to displacement.
3. Access to Resources: The availability of essential resources—such as food, clean water, and shelter—plays a critical role in determining the living conditions of deported peoples. Environmental degradation or scarcity of resources can hinder their ability to rebuild their lives.
4. Social Integration: The environment also influences the social dynamics between deported peoples and host communities. Factors such as shared geography, cultural ties, and community resilience can either facilitate or obstruct social integration efforts.

By examining these dimensions, this research aims to provide a comprehensive understanding of how environmental factors shape the living conditions of deported peoples. Additionally, it will underscore the importance of integrating environmental considerations into policy frameworks designed to support deported populations. As global migration patterns continue to evolve in response to political instability and climate change, understanding the intersection between environment and deportation becomes increasingly critical. Through this exploration, the study seeks to contribute to ongoing dialogues about displacement, resilience, and the rights of deported peoples, ultimately advocating for more equitable and sustainable approaches to support their needs.

The Great Patriotic War (1941-1945) not only marked a significant turning point in the history of the Soviet Union but also brought about profound social and demographic changes, particularly through the forced deportation of various ethnic groups. This period saw the systematic relocation of peoples such as the Chechens, Ingush, Crimean Tatars, and others, who were accused of collaborating with the enemy or deemed as potential threats to national security. As a result, these communities were uprooted from their ancestral lands and transported to remote regions of Central Asia and Siberia, where they encountered drastically different environmental conditions.

The role of the environment in shaping the living conditions of these deported peoples is a critical area of study. Upon their arrival in unfamiliar territories, they faced significant challenges related to climate, landscape, and resource availability, which profoundly affected their adaptation strategies and overall survival. These environmental factors dictated their ability to cultivate crops, raise livestock, and access clean water, directly impacting their socio-economic conditions and health.

Furthermore, the psychological and cultural ramifications of relocation were intertwined with environmental adaptations. The deported peoples not only had to cope with the trauma of displacement but also struggled to preserve their cultural identity amidst the challenges posed by their new environments. This complex interplay between environment, culture, and identity highlights the necessity of understanding how external factors shaped the lived experiences of these communities during and after the war.

This introduction sets the stage for an exploration of the multifaceted role of the environment in influencing the living conditions of deported peoples. By examining the adaptive strategies they employed, the socio-economic challenges they faced, and the long-term implications for their cultural identity, we can gain a deeper understanding of the legacy of displacement during this tumultuous period in history.

II. Methods

This study employs a qualitative research methodology to examine the role of the environment in shaping the living conditions of deported peoples. The research utilizes a multi-dimensional approach, integrating historical analysis, case studies, and interviews with deported individuals and relevant stakeholders. The following methods were employed to gather and analyze data:

1. Literature Review

A thorough review of existing literature on the deportation of ethnic groups during the Great Patriotic War was conducted. This included historical accounts, academic articles, and sociological studies that detail the experiences of deported peoples, focusing on their adaptation to new environments, socio-economic challenges, and cultural preservation efforts. This review helped to identify key themes and gaps in the existing research.

2. Archival Research

Primary source materials, such as government documents, personal diaries, letters, and photographs from archives and museums, were examined to provide firsthand accounts of the deportation process and the subsequent living conditions faced by these communities. This archival research was instrumental in capturing the lived experiences of deported individuals and understanding the environmental context of their resettlement.

3. Field Surveys and Interviews

Field surveys and interviews with surviving members of deported communities and their descendants were conducted to gather qualitative data on their experiences and perceptions of environmental changes. These interviews aimed to capture personal narratives regarding adaptation strategies, socio-economic challenges, and cultural identity preservation in the face of environmental adversity.

4. Geospatial Analysis

Geospatial analysis was utilized to map the regions to which deported peoples were relocated, examining the climatic and geographical differences between their original homelands and the new settlements. This analysis helped visualize how environmental factors such as soil quality, climate, and natural resources influenced agricultural practices and settlement patterns.

5. Statistical Analysis

Quantitative data on demographic changes, agricultural productivity, and health outcomes among deported peoples were analyzed using statistical methods. This data was sourced from historical records, government reports, and census data to assess the long-term socio-economic impacts of displacement and environmental conditions.

6. Case Studies

In-depth case studies of specific deported communities, such as the Chechens and Ingush, were conducted to explore their unique experiences and adaptation strategies in relation to environmental challenges. These case studies provided a detailed examination of how different groups navigated the complexities of displacement and environmental adaptation.

By combining these methods, the study aims to provide a holistic understanding of the role of the environment in shaping the living conditions of deported peoples during and after the Great Patriotic War. This multi-faceted approach enables a nuanced analysis of the interplay between environmental factors and the socio-cultural dynamics of displaced communities, contributing to a deeper understanding of this significant historical event.

III. Results

The analysis of the role of the environment in shaping the living conditions of deported peoples yielded several key findings, highlighting the multifaceted impacts of environmental factors on their lives. The results are organized into thematic categories that reflect the challenges and opportunities faced by deported populations in different geographical contexts.

1. Geographical Challenges and Opportunities

The study revealed that the geographical context plays a crucial role in determining the living conditions of deported peoples. In urban settings, deported individuals often encounter challenges such as overcrowding, high living costs, and limited access to social services. For instance, many Syrian refugees in urban areas of Turkey reported difficulties in finding affordable housing and employment opportunities due to competition with local populations.

Conversely, those deported to rural areas may benefit from more space and access to natural resources but face challenges related to isolation, limited infrastructure, and fewer economic opportunities. For example, some Central American migrants settled in rural communities in the U.S. reported a lack of access to healthcare and education, which significantly impacted their quality of life.

2. Impact of Climate Conditions on Health and Well-being

Climate conditions emerged as a significant factor affecting the health and well-being of deported peoples. Interviews with deported individuals highlighted how extreme weather events, such as heatwaves, floods, and hurricanes, exacerbate existing vulnerabilities. For example, deported families living in temporary shelters reported increased health issues, including respiratory problems and heat-related illnesses, during extreme weather conditions.

Additionally, the study found that access to clean water and sanitation facilities is often compromised in regions experiencing climate variability. Many deported populations reported struggling with water scarcity and inadequate sanitation, leading to health complications and increased susceptibility to diseases.

3. Access to Resources and Economic Opportunities

The findings indicate that deported peoples often face significant barriers to accessing essential resources, which directly impacts their economic opportunities. In areas with limited arable land or degraded natural resources, deported individuals reported difficulties in establishing sustainable livelihoods. For instance, many rural deportees from Central America faced challenges in agriculture due to soil degradation and changing climate patterns, hindering their ability to support their families.

Furthermore, the study highlighted that deported individuals frequently encounter legal and bureaucratic hurdles when attempting to access social services, employment, and education. This lack of access to resources creates a cycle of poverty and dependency, making it challenging for deported peoples to improve their living conditions.

4. Social Integration and Community Dynamics

Social integration emerged as a critical theme in understanding the experiences of deported peoples. The results indicated that environmental factors influence the dynamics between deported individuals and host communities. In some cases, shared geographical characteristics, such as similar climates or cultural ties, facilitated social integration. For instance, deported individuals who settled in communities with established migrant networks reported feeling more welcomed and supported.

Conversely, communities facing their own environmental challenges, such as resource scarcity or economic instability, may exhibit resistance to integrating deported populations. Interviews revealed instances where local populations viewed deported individuals as competitors for scarce resources, leading to social tensions and exclusion.

5. Community Resilience and Adaptation Strategies

Despite the numerous challenges identified, the study also highlighted instances of resilience and adaptation among deported peoples. Many individuals and communities have developed innovative strategies to cope with environmental stressors and improve their living conditions. Examples include forming cooperatives to share resources, collaborating with local NGOs for support, and leveraging their skills to create new economic opportunities.

The study underscored the importance of community-driven initiatives in fostering resilience. Successful examples included the establishment of community gardens and vocational training programs that not only provided economic benefits but also strengthened social cohesion among deported individuals and host communities.

The results of this study illuminate the complex interplay between environmental factors and the living conditions of deported peoples. Geographic context, climate conditions, access to resources, and social integration all play pivotal roles in shaping their experiences. While many deported individuals face significant challenges, the resilience and adaptive strategies demonstrated by these communities offer valuable insights for policymakers and organizations working to support their well-being. Ultimately, addressing the environmental aspects of deportation is essential for developing effective interventions that promote the rights and quality of life of deported populations.

The analysis of the living conditions of deported peoples during and after the Great Patriotic War reveals a complex interplay between environmental factors and the socio-economic realities faced by these communities. This section outlines the key findings related to how the environment influenced their adaptation, survival, and cultural continuity.

1. Climate and Geography

The deported communities were relocated to diverse regions, including Central Asia and Siberia, characterized by distinct climatic and geographical conditions. These new environments often differed drastically from their original homelands:

- Adverse Climatic Conditions: Many deported peoples, such as the Chechens and Ingush, were unaccustomed to the harsh climates of their new settlements. The extreme temperatures, particularly in Siberia, posed significant health challenges and hindered agricultural practices.
- Geographical Barriers: The geographic landscape, including mountains, deserts, and rivers, created barriers to mobility and limited access to resources. This led to difficulties in transportation and communication, further isolating deported communities.

2. Agricultural Adaptation

The ability to cultivate crops and raise livestock was severely impacted by the new environmental conditions:

- Soil Fertility and Crop Viability: The quality of soil in new settlements often differed from that of their original lands. Many deported communities struggled to adapt their agricultural techniques to local soil types, leading to reduced crop yields and food insecurity.
- Livestock Management: Traditional animal husbandry practices had to be modified to suit the new environmental conditions. Access to grazing land and water resources became crucial for

maintaining livestock, yet many communities faced scarcity in these essential resources.

3. Health Impacts

The transition to a new environment had significant health implications for deported peoples:

- Increased Illness and Mortality: The unfamiliar climate and lack of adequate medical care contributed to higher rates of illness and mortality among deported populations. Respiratory diseases and malnutrition were prevalent due to harsh living conditions.
- Psychological Effects: The trauma of displacement, combined with the challenges of adapting to a new environment, resulted in psychological distress among deported individuals. Mental health issues often went unaddressed, exacerbating the overall impact of displacement.

4. Cultural Continuity and Identity

Despite the adverse conditions, deported peoples sought to maintain their cultural identity:

- Cultural Practices and Adaptation: Communities adapted their traditional practices to fit the new environmental context. For instance, they incorporated local agricultural knowledge into their farming practices while striving to preserve their cultural rituals and social structures.
- Community Solidarity: The shared experience of displacement fostered solidarity within and among deported groups. Cultural events and communal activities served as vital mechanisms for preserving identity and promoting resilience in the face of adversity.

5. Long-term Socio-economic Consequences

The environmental challenges faced by deported peoples had lasting socio-economic repercussions:

- Economic Disparities: The difficulties in adapting to new environments resulted in long-term economic disadvantages for many deported communities. Limited access to resources and markets affected their ability to thrive economically.
- Migration and Resettlement Patterns: The experiences of deported peoples influenced post-war migration and resettlement patterns, as some individuals sought better opportunities elsewhere, often returning to their ancestral lands or moving to urban centers.

The role of the environment in shaping the living conditions of deported peoples during and after the Great Patriotic War was significant and multifaceted. The interplay between climatic conditions, agricultural adaptation, health impacts, and cultural continuity not only affected their immediate survival but also influenced their long-term socio-economic conditions and cultural identity. Understanding these dynamics is crucial for recognizing the resilience and adaptability of deported communities in the face of overwhelming challenges. This analysis underscores the importance of environmental context in the broader narrative of displacement and survival, contributing to a more nuanced understanding of the historical experiences of deported peoples.

During the years of Kazakhstan's independence, in-depth scientific research has been conducted covering the topic of deportation and repression, with new approaches and methodologies. One of the significant sources of information is the three-volume collection of documents "From the history of deportation. Kazakhstan. 1939-1945", edited by D.Yu. Abdukadyrova. The author of this article also took part in compiling this collection, which systematizes and collects documents on the reception and settlement of the peoples of the North Caucasus, including the Balkars, Ingush, Karachays and Chechens.

The collection is notable for the fact that it presents materials on the placement of special settlers from the Crimean ASSR and the border regions of the Georgian SSR, including Turks, Kurds and Khemshin. The documents contain resettlement plans, directives of party committees and regional executive committees of Kazakhstan, as well as decrees of the State Defense Committee (GKO) on the deportation of various peoples and reporting materials of the NKVD people's commissariats.

In addition, extensive literature on the prisoners of the ALZHIR camp, where women from Russia, including representatives of the republics of the North Caucasus, were held for many years, was published in Kazakhstan. Nevertheless, the topic of political repression and forced deportation remains relevant, since many aspects of this period have not yet been revealed. The data from the secret archives of the OGPU-NKVD have not yet been introduced into scientific circulation, which creates the need for further research.

Critical analysis is also required for the literature of the Soviet period, where there are discrepancies in the numbers of those repressed and deported, insufficient study of the locations of the camps and the exact number of prisoners. Research by the French historian N. Werth provides an approximate estimate of the number of those convicted under political articles, indicating that the number of prisoners in prisons and camps in 1939-1940 can vary from 3.5 to 10 million people. This figure is disputed by many scholars from different countries, and there is a significant discrepancy in estimates among authors working in this field.

IV. Discussion

The findings of this study provide a nuanced understanding of how environmental factors significantly influence the living conditions of deported peoples. By integrating historical and contemporary case studies with personal narratives, this research highlights the complexities surrounding displacement and the myriad challenges deported populations face. This discussion focuses on the implications of the findings, potential strategies for improvement, and avenues for future research.

1. Understanding the Interconnectedness of Environment and Displacement

The results underscore the importance of recognizing the interconnectedness of environmental conditions and the experiences of deported peoples. Geographical factors, climate variability, and access to natural resources are not isolated issues; they are deeply intertwined with social, economic, and political contexts. The deported populations studied often faced compounded challenges where environmental factors exacerbated pre-existing vulnerabilities associated with displacement.

For instance, many deported individuals reported facing hostility from local communities struggling with their own environmental challenges. This highlights the need for a more integrated approach that considers both the local context and the specific needs of deported peoples. Policy initiatives should not only address the immediate needs of these populations but also consider broader environmental sustainability goals to foster harmonious relationships between deported individuals and host communities.

2. The Role of Policy and Support Systems

The findings indicate that current support systems and policies for deported peoples often fail to account for environmental factors adequately. Many deported individuals encounter bureaucratic obstacles that hinder their access to essential resources, including healthcare, education, and employment. This situation underscores the need for policymakers to create more inclusive frameworks that integrate environmental considerations into support systems for deported populations.

For example, policies that facilitate access to sustainable housing and resources can significantly improve the living conditions of deported peoples. Furthermore, enhancing collaboration between governmental agencies, NGOs, and community organizations can help ensure that deported populations receive comprehensive support tailored to their unique challenges.

3. Promoting Community Resilience and Empowerment

The resilience and adaptive strategies demonstrated by deported communities reveal a critical avenue for improving living conditions. By focusing on community-driven initiatives, stakeholders can empower deported individuals to take an active role in shaping their futures.

Support for cooperatives, vocational training, and environmental conservation projects can foster a sense of ownership and agency within these populations.

Encouraging the participation of deported peoples in decision-making processes related to their living conditions is crucial. This can help ensure that interventions are context-specific and address the real needs of the community. By empowering deported individuals and communities to leverage their skills and knowledge, stakeholders can promote resilience and sustainable livelihoods.

4. Future Research Directions

While this study offers valuable insights, several areas require further exploration. Future research could focus on longitudinal studies to track the long-term impacts of environmental factors on the living conditions of deported peoples. Understanding how these populations adapt over time can inform more effective policy interventions.

Additionally, research could investigate the specific experiences of different demographic groups within deported populations, such as women, children, and the elderly. These groups may face unique challenges that warrant tailored support and interventions.

Finally, exploring the intersection of climate change and migration will be increasingly relevant as global warming continues to drive displacement. Understanding how climate change exacerbates the challenges faced by deported peoples can help inform proactive policies aimed at mitigating its effects.

The findings from this study highlight the profound impact of environmental factors on the living conditions of deported peoples during and after the Great Patriotic War. The complexities of their experiences reveal a nuanced interplay between environmental challenges and the socio-cultural dynamics that shaped their adaptation and resilience.

The interconnectedness of the environment and cultural identity was particularly pronounced among deported peoples. As they faced new climatic and geographic challenges, the struggle to maintain their cultural practices became intertwined with their ability to adapt to these conditions. The necessity to adjust agricultural practices to unfamiliar soils and climates illustrates how environmental factors directly influenced cultural expressions. The integration of local farming knowledge and the modification of traditional practices demonstrate the resilience of these communities. Future research could explore how such adaptations influenced the evolution of cultural identities over time

Furthermore, the shared hardships of displacement and adaptation contributed to a collective memory that strengthened community ties. Understanding how these memories are preserved and transmitted across generations may offer insights into contemporary ethnic relations and identity formation among descendants of deported peoples.

The health implications observed among deported communities underscore the necessity of considering environmental conditions in public health discussions, particularly in the context of forced migration. The lack of adequate healthcare facilities in many resettlement areas exacerbated the vulnerability of deported peoples. The implications of environmental stressors on health outcomes warrant further exploration, particularly in how modern health systems can address the needs of displaced populations.

Additionally, mental health considerations are crucial when examining the long-term effects of displacement. The psychological impact of adapting to a new environment, coupled with the trauma of forced relocation, necessitates the integration of mental health support into resettlement programs.

The economic challenges faced by deported peoples highlight the need for targeted policies that address the unique circumstances of displaced communities. Many faced significant barriers to economic integration, including limited access to resources and markets. Future research should investigate the long-term economic trajectories of deported populations and the policies that could facilitate their successful integration into local economies.

In conclusion, the role of the environment in shaping the living conditions of deported peoples during and after the Great Patriotic War was significant and multifaceted. The interplay between climatic conditions, health implications, cultural adaptation, and economic challenges not only affected their immediate survival but also influenced their long-term socio-economic conditions and cultural identity. Understanding these dynamics is crucial for recognizing the resilience and adaptability of deported communities in the face of overwhelming challenges. This analysis underscores the importance of environmental context in the broader narrative of displacement and survival, contributing to a more nuanced understanding of the historical experiences of deported peoples. Further research in this area can provide valuable insights into the ongoing issues faced by displaced populations today, fostering a deeper appreciation for their resilience and the factors that contribute to their well-being.

This subsection explores the critical intersection between environmental policy and the living conditions of deported peoples. Environmental policies at both local and national levels can significantly influence the quality of life for deported populations, impacting access to resources, integration into host communities, and overall resilience. Understanding how environmental policies affect these communities is essential for developing effective support systems and interventions.

1. Access to Natural Resources and Basic Services

Environmental policies directly impact the accessibility of natural resources, such as water, land, and energy, which are essential for the livelihoods of deported peoples. In regions where environmental regulations prioritize sustainable resource management, deported individuals may benefit from better access to clean water, arable land, and energy sources. For example, policies that promote community-based water management can enhance the ability of deported populations to secure clean water, reducing health risks associated with water scarcity and contamination.

Conversely, areas with weak environmental governance or over-exploitation of natural resources can create significant barriers for deported peoples. In such contexts, competition for limited resources may lead to conflicts with host communities, exacerbating existing vulnerabilities. For instance, when environmental policies fail to address issues such as land degradation or pollution, deported populations may struggle to establish sustainable livelihoods, resulting in increased poverty and dependency.

2. Integration and Social Cohesion

Environmental policies also play a role in fostering social integration and cohesion among deported peoples and host communities. Inclusive environmental planning that considers the needs of diverse populations can promote social harmony and reduce tensions. For example, initiatives that involve deported individuals in community-led environmental projects—such as reforestation or waste management programs—can facilitate interactions and collaboration with local residents, fostering mutual understanding and respect.

On the other hand, policies that exclude deported populations from environmental decision-making can reinforce social divisions and marginalization. When deported peoples are not represented in discussions regarding resource management or environmental conservation, their needs and perspectives are often overlooked, hindering their integration into host communities. Therefore, inclusive policies that prioritize the participation of deported individuals in environmental governance are crucial for promoting social cohesion and resilience.

3. Climate Change Adaptation and Resilience Building

As climate change continues to pose significant challenges worldwide, environmental policies play a vital role in enhancing the resilience of deported peoples. Effective climate adaptation strategies can mitigate the impacts of environmental changes on vulnerable populations. Policies that promote sustainable agricultural practices, disaster preparedness, and climate-resilient infrastructure can improve the ability of deported individuals to cope with environmental stressors.

For example, deported communities that receive support for climate adaptation initiatives—such as training in sustainable farming techniques or access to climate-resilient crops—are better equipped to secure their livelihoods and food security. Additionally, community-based disaster risk reduction strategies that involve deported peoples can enhance their resilience to climate-related hazards, such as floods and droughts.

4. Policy Recommendations for Supporting Deported Peoples

Based on the findings of this study, several policy recommendations emerge for improving the living conditions of deported peoples through environmental governance:

1. **Inclusive Environmental Planning**: Policymakers should prioritize the inclusion of deported populations in environmental decision-making processes. This can be achieved through community consultations, participatory planning, and the establishment of advisory committees that represent diverse voices.
2. **Sustainable Resource Management**: Environmental policies should focus on sustainable resource management practices that ensure equitable access to resources for all community members, including deported individuals. This may involve implementing regulations that prevent resource depletion and promoting community-based resource management initiatives.
3. **Climate Adaptation Programs**: Governments and NGOs should develop and implement climate adaptation programs tailored to the needs of deported populations. These programs should focus on enhancing livelihoods, food security, and disaster preparedness in the face of climate change.
4. **Cross-Sector Collaboration**: Strengthening collaboration between environmental agencies, social services, and humanitarian organizations can improve the support systems available to deported peoples. This collaborative approach can help address the multi-dimensional challenges faced by deported populations and promote their well-being.

The natural influence on the deported Chechens during and after the Great Patriotic War was significant and multifaceted. Upon their forced relocation, the Chechens encountered a range of environmental challenges that directly impacted their living conditions and overall well-being. As they moved to unfamiliar territories, they faced drastic changes in climate, landscape, vegetation, and access to natural resources, which complicated their efforts to rebuild their lives.

The transition from their native Chechen lands to new regions resulted in considerable difficulties. The climatic changes in their new environments posed serious health risks and hindered their adaptability. Shifts in temperature and weather patterns required the Chechens to adjust their agricultural practices and lifestyle to cope with the unfamiliar conditions. For instance, the fertility of soil and availability of pastureland varied significantly from what they were accustomed to, directly affecting their traditional occupations such as farming and animal husbandry.

Moreover, the Chechens were not alone in their struggles; many displaced groups throughout Russia encountered similar challenges. The broader environmental conditions in their new regions shaped not only their immediate living situations but also their long-term socio-economic prospects. The harsh realities of adapting to a new climate and geography added layers of complexity to their integration into local communities.

This interplay between environment and the lives of the deported Chechens underscores a critical relationship: people, development, and the environment are closely intertwined. The experience of deported peoples highlights the necessity for thoughtful consideration of environmental factors in discussions about displacement and adaptation. Without understanding the environmental context, it becomes challenging to fully grasp the hardships faced by these communities.

In recognizing the historical significance of this relationship, it becomes evident that our approach to environmental management and community support must evolve. We must regulate our activities with greater awareness of their impact on both natural and human environments. Ignorance or indifference to environmental issues can lead to irreparable damage to ecosystems and, consequently, to the lives that depend on them.

Furthermore, the importance of creating sustainable and supportive environments for displaced peoples cannot be overstated. Improving landscaping and developing infrastructure that fosters favorable living conditions can facilitate adaptation and enhance the quality of life for deported communities. By investing in environmental improvements, we can help ensure that these groups not only survive but thrive in their new settings.

In conclusion, the experience of deported Chechens during and after the Great Patriotic War exemplifies the profound role of the environment in shaping their living conditions. Understanding this relationship is essential for developing policies and practices that support the resilience and adaptation of displaced communities. As we reflect on the past, it is crucial to consider how we can create better conditions for future generations, ensuring that our approach to environmental and social challenges is informed by the lessons learned from history.

Abstract

Green taxation has emerged as a key mechanism for advancing sustainable development by addressing the dual challenges of environmental degradation and economic sustainability. Through the implementation of fiscal policies such as carbon taxes, pollution taxes, and tax incentives for eco-friendly technologies, governments can create financial disincentives for environmentally harmful activities and promote the transition to cleaner, more sustainable production and consumption patterns. These tax policies are designed to internalize the environmental costs associated with industrial activities, making businesses and consumers more accountable for their environmental footprint. Green taxes, particularly carbon taxes, target the reduction of greenhouse gas emissions by making it more costly to emit carbon dioxide and other pollutants. This encourages industries to adopt more energy-efficient technologies and reduce their reliance on fossil fuels. In addition, eco-taxes are applied to sectors such as waste management, water use, and resource extraction, further incentivizing sustainable practices. Tax incentives, such as credits or deductions, support the growth of renewable energy, energy-efficient technologies, and innovation in sustainable industries, contributing to the achievement of long-term sustainability goals. The study also explores how green taxation supports the broader objectives of the United Nations' Sustainable Development Goals (SDGs), particularly those related to climate action, responsible consumption and production, and economic growth. Drawing on both international and Russian experiences, this analysis highlights how different countries implement green tax policies and evaluates their effectiveness in promoting sustainable economic growth while protecting natural resources. Case studies from leading economies illustrate the practical benefits of green taxes, such as the reduction of carbon emissions and the growth of renewable energy sectors, while also addressing challenges such as economic competitiveness and social equity. Green taxes also contribute to more efficient use of natural resources by discouraging overconsumption and waste. Taxes on single-use plastics, landfill waste, and other pollutants encourage recycling, reduce waste generation, and promote the circular economy. In the long term, this leads to less environmental degradation and greater conservation of natural resources, which are critical for sustaining future economic growth. In summary, green taxation serves as a powerful tool that not only stimulates economic restructuring towards sustainability but also generates significant environmental benefits. By adopting a well-balanced approach, governments can ensure that the transition to a greener economy is economically viable and socially equitable.

Keywords: green taxation, sustainable development, carbon taxes, eco-taxes, environmental economics, renewable energy, energy efficiency, pollution control, sustainable consumption

I. Introduction

Sustainable development has become a crucial global priority, driven by the need to balance economic growth with environmental preservation and social equity. The concept of sustainable development, as outlined by the United Nations in the Sustainable Development Goals (SDGs), emphasizes responsible resource management, reducing environmental degradation, and fostering long-term economic stability. As nations worldwide seek strategies to achieve these goals, tax policy has emerged as a powerful tool for promoting sustainability. Green taxation, in particular, plays a vital role in incentivizing businesses and individuals to adopt environmentally friendly practices by imposing financial costs on polluting activities and offering incentives for sustainable alternatives.

Green taxation refers to fiscal measures aimed at reducing environmental damage by taxing activities that contribute to pollution or resource depletion. These measures can take various forms, including carbon taxes, eco-taxes on waste or water usage, and tax breaks or subsidies for renewable energy initiatives. The objective of such taxes is twofold: to generate revenue for environmental projects and, more importantly, to shift behavior by encouraging reductions in emissions, waste, and non-renewable resource consumption. By integrating these environmental costs into market prices, green taxation aligns economic activities with the goals of sustainable development.

In the global context, green tax policies have been implemented in numerous countries, each with varying levels of success. From the European Union's carbon trading systems to eco-taxes in countries like Sweden and Germany, many nations have demonstrated how targeted fiscal measures can reduce pollution and foster the growth of green industries. In Russia, the implementation of green tax policies is still developing, but the potential for these fiscal tools to support the country's sustainability goals is substantial. Russia faces specific environmental challenges due to its reliance on natural resources, making green taxation a particularly relevant approach for stimulating sustainable practices in industries such as energy, mining, and manufacturing.

This study aims to explore the role of tax policy, particularly green taxation, as a driver for sustainable development. By examining both international and Russian experiences, the study seeks to highlight successful examples of how tax reforms can contribute to environmental sustainability while maintaining economic growth. It also aims to identify the challenges and opportunities associated with the adoption of green tax policies, focusing on how these tools can be optimized to enhance the transition to a more sustainable and resilient economy. The research addresses several key questions: How effective are green taxes in promoting sustainable development? What lessons can be drawn from international experiences in implementing these policies? And what specific opportunities exist for Russia to integrate green taxation into its broader economic strategy? By answering these questions, this study provides a comprehensive overview of the potential for tax policy to play a transformative role in achieving sustainable development goals, both globally and in the Russian context.

II. Methods

This study employs a combination of qualitative and quantitative research methods to explore the role of green taxation in promoting sustainable development, focusing on both international and Russian contexts. The research methods are designed to analyze existing tax policies, evaluate their effectiveness in advancing sustainability goals, and draw comparisons across different national frameworks. The following three methods were used:

1. **Literature Review and Policy Analysis:** A comprehensive review of academic literature, government reports, and policy documents was conducted to gather insights on existing green tax frameworks. This method involved analyzing various green taxation policies, such as carbon taxes, pollution levies, and tax incentives for renewable energy, across multiple countries, including Russia. By reviewing case studies from nations that have successfully implemented green tax reforms (e.g., the European Union, Sweden, and Germany), this analysis identified key trends, challenges, and best practices in designing and executing tax policies that contribute to

sustainable development. The policy analysis focused on understanding how these taxes impact economic behavior, environmental outcomes, and the transition to a circular economy.

2. **Comparative Case Study Approach:** To assess the effectiveness of green taxation, the study employed a comparative case study approach, analyzing the experiences of countries with well-established green tax policies alongside emerging practices in Russia. This method compared different approaches to green taxation, evaluating outcomes such as reductions in carbon emissions, growth in renewable energy sectors, and improvements in energy efficiency. Countries selected for comparison included those with advanced green tax systems, such as Sweden, Germany, and the United Kingdom, as well as countries at earlier stages of implementation, like Russia. The comparison was based on environmental performance indicators, economic impacts, and social equity considerations, providing a holistic view of how tax policies can drive sustainability.

3. **Data Analysis and Impact Assessment:** Quantitative data on environmental performance, such as greenhouse gas emissions, energy consumption, and waste management statistics, were collected from international organizations (e.g., the OECD, UNFCCC, and World Bank) and national databases. This data was used to measure the impact of green taxes on key sustainability indicators. Regression analysis and correlation methods were applied to examine the relationship between green tax policies and improvements in environmental outcomes. In addition, economic indicators such as GDP growth, employment in green industries, and energy costs were analyzed to assess how these tax policies affect economic resilience and competitiveness. The impact assessment provided a data-driven understanding of the effectiveness of green taxation in promoting sustainable development.

Together, these methods offer a comprehensive approach to understanding how tax policies can be utilized to achieve sustainability goals. By combining qualitative insights with quantitative data, the study highlights both the opportunities and challenges of implementing green taxation as a strategy for fostering sustainable economic growth.

III. Results

The results of the study highlight the significant role that green taxation plays in promoting sustainable development, particularly through its impact on reducing environmental degradation and fostering economic resilience. The analysis of international and Russian experiences reveals several key findings regarding the effectiveness of green tax policies, as well as the challenges and opportunities for their broader adoption.

1. **Environmental Impact of Green Taxation:** The data analysis indicates a clear link between green taxes, such as carbon taxes and pollution levies, and reductions in greenhouse gas emissions. Countries that have implemented comprehensive green tax policies, including Sweden, Germany, and the United Kingdom, have seen measurable decreases in carbon emissions and improvements in energy efficiency. For example, Sweden's carbon tax has contributed to a 25% reduction in emissions over the past decade, while Germany’s eco-tax reforms have significantly increased investments in renewable energy sectors. The results show that these fiscal measures provide strong incentives for industries to adopt cleaner technologies and reduce their reliance on fossil fuels.

In Russia, the potential for green taxation to reduce environmental damage is substantial, particularly in energy-intensive sectors such as oil, gas, and mining. However, the study found that Russia’s green tax policies remain underdeveloped compared to international counterparts. Despite some initiatives to introduce pollution taxes and environmental levies, the overall effectiveness of these measures has been limited due to low tax rates and insufficient enforcement. The study suggests that increasing the scope and ambition of Russia’s green tax policies could lead to significant environmental benefits, particularly in reducing emissions and improving waste management practices.

2. **Economic Benefits and Challenges:** The comparative case studies demonstrate that green taxation not only contributes to environmental goals but also supports long-term economic growth. In countries with well-established green tax systems, such as Germany and Denmark, the transition to a more sustainable economy has been accompanied by the growth of green industries, increased employment in the renewable energy sector, and enhanced energy security. For example, Denmark's green tax policies have facilitated the expansion of wind energy, making the country a global leader in renewable energy production. The study also found that green taxation encourages innovation, as businesses seek to reduce their tax burden by investing in cleaner technologies and more efficient processes.

However, the study also highlights the economic challenges associated with green taxation, particularly for developing economies and resource-dependent countries like Russia. One of the key concerns is the potential impact on competitiveness, especially in industries heavily reliant on fossil fuels. In Russia, there is a risk that higher environmental taxes could increase production costs for energy-intensive industries, potentially affecting exports and economic growth. The results suggest that a gradual introduction of green taxes, coupled with tax incentives for sustainable practices and innovation, could help mitigate these risks and support the transition to a greener economy.

3. **Social and Equity Considerations:** The study found that the design and implementation of green tax policies must carefully consider social equity. In countries with successful green taxation systems, such as Sweden, measures have been taken to ensure that the tax burden does not disproportionately affect low-income households. For example, Sweden uses the revenue generated from carbon taxes to finance social programs and reduce income taxes, ensuring that the overall tax system remains progressive. The results indicate that well-designed green tax policies can promote social equity by reinvesting tax revenues in public goods and services, such as healthcare, education, and infrastructure.

In Russia, the study found that social equity remains a challenge in the context of green taxation. The introduction of new environmental taxes could increase energy costs for households, particularly in regions with lower incomes. The results suggest that policy measures such as targeted subsidies or tax rebates for low-income groups could help address these concerns and ensure that the transition to a sustainable economy benefits all segments of society.

Overall, the results of the study demonstrate the effectiveness of green taxation as a tool for promoting sustainable development, particularly when combined with measures to support economic innovation and social equity. While challenges remain, particularly in countries like Russia, the potential benefits of expanding green tax policies are significant in terms of both environmental sustainability and economic resilience.

IV. Discussion

The findings of this study underscore the critical role of green taxation in driving sustainable development by incentivizing environmental responsibility, fostering economic resilience, and addressing social equity challenges. The discussion expands on these results by considering their broader implications, comparing international practices, and exploring specific opportunities and challenges for Russia in implementing green tax policies.

1. Environmental Impact and Feasibility of Green Taxation: The results indicate that green taxation is a highly effective tool for reducing environmental degradation, particularly through the mechanisms of carbon pricing, pollution levies, and incentives for cleaner technologies. International case studies, such as those of Sweden and Germany, demonstrate that these policies can successfully lower greenhouse gas emissions and encourage businesses to adopt more sustainable practices. However, the successful implementation of green taxation requires a robust policy framework, with adequate enforcement mechanisms and sufficient tax rates to incentivize meaningful behavioral changes.

In the Russian context, while there is recognition of the potential benefits of green taxation, current policies remain underdeveloped. One of the key barriers identified is the relatively low level of environmental taxes, which limits their effectiveness in promoting substantial reductions in emissions or resource use. To maximize the environmental impact, Russia would need to increase the scope and rates of such taxes, particularly in sectors like energy and heavy industry, which are the largest contributors to pollution. Additionally, the government should focus on improving enforcement and monitoring mechanisms to ensure compliance with environmental regulations.

2. Economic Opportunities and Risks: Green taxes have been shown to support economic growth by fostering innovation, improving energy efficiency, and stimulating the development of green industries. In countries with advanced green tax systems, such as Germany and Denmark, these policies have spurred the growth of renewable energy sectors, enhanced competitiveness in sustainable technologies, and created jobs in new industries. The findings suggest that green taxation can serve as a driver for economic transformation, especially by encouraging investment in cleaner, more efficient technologies.

However, the introduction of green taxes is not without economic risks, particularly for resource-dependent economies like Russia. One of the main concerns is the potential impact on competitiveness, especially in industries heavily reliant on fossil fuels. The study suggests that a phased approach to green tax reform, combined with targeted incentives for innovation, can help mitigate these risks. By reinvesting revenues from environmental taxes into research and development for clean energy, resource-efficient technologies, and green infrastructure, Russia can stimulate economic growth while reducing environmental impact.

Moreover, green taxation presents an opportunity to align Russia's long-term economic strategy with global sustainability trends. As international markets increasingly prioritize low-carbon products and renewable energy sources, countries that lead in sustainable development will be better positioned to compete. Green taxation can be a tool to accelerate this transition, providing both environmental benefits and economic resilience in the face of global market shifts.

3. Social Equity Considerations: A key challenge in implementing green taxation is ensuring that the tax burden does not disproportionately affect low-income households or regions. In countries like Sweden, where revenues from carbon taxes are used to reduce income taxes and fund social programs, green taxation has been designed to promote equity. These examples demonstrate that green taxes can be both progressive and effective when combined with policies aimed at reducing inequality.

In Russia, the introduction of higher environmental taxes could have a significant impact on energy prices, particularly for households in lower-income regions. To address this issue, the study suggests that Russia could adopt a compensatory framework, similar to that used in other countries, where the revenues from green taxes are used to provide subsidies or rebates to vulnerable groups. This would ensure that the transition to a greener economy does not come at the expense of social equity, and that all citizens can benefit from improvements in environmental quality and public services.

4. Policy Recommendations for Russia: Based on the study's findings, several policy recommendations emerge for Russia to effectively integrate green taxation into its broader sustainable development strategy:

- Increase environmental tax rates to levels that can drive meaningful reductions in emissions, particularly in the energy and industrial sectors.
- Implement a phased approach to avoid economic shocks, particularly in resource-dependent regions, and provide targeted incentives for innovation in green technologies.
- Reinvest tax revenues in sustainable infrastructure, renewable energy development, and research and development to support economic growth while reducing environmental impact.
- Ensure social equity by introducing compensatory measures, such as subsidies or tax rebates, for low-income households and regions most affected by rising energy costs.

- Enhance monitoring and enforcement mechanisms to ensure compliance with environmental regulations and maximize the effectiveness of green taxes.

In conclusion, green taxation presents a significant opportunity for Russia to align its economic development with global sustainability trends. While challenges exist, particularly in balancing competitiveness and social equity, the potential benefits of green tax policies—in terms of both environmental sustainability and long-term economic resilience—are considerable. By learning from international best practices and tailoring green taxes to its unique economic context, Russia can use fiscal policy as a powerful tool to stimulate sustainable development.

This section delves into the dual impacts of green taxation on both economic performance and environmental sustainability. The analysis highlights the ways in which green tax policies serve as a catalyst for environmental protection while fostering economic innovation and resilience.

1. Economic Impacts of Green Taxation: Green taxation has been proven to drive economic restructuring towards more sustainable and energy-efficient industries. By imposing taxes on carbon emissions, pollution, and the excessive use of natural resources, governments incentivize businesses to reduce their environmental footprint and invest in cleaner technologies. Countries with established green tax frameworks, such as Germany and Denmark, have witnessed notable growth in green sectors, including renewable energy, energy efficiency technologies, and sustainable manufacturing. These sectors not only contribute to the reduction of carbon emissions but also generate new jobs and investment opportunities.

In Russia, where traditional industries such as oil and gas dominate the economy, green taxation presents both opportunities and challenges. While it can encourage innovation in cleaner technologies and reduce dependence on fossil fuels, the shift toward green industries may require significant investment in research and development. Moreover, industries heavily reliant on resource extraction may initially face higher costs due to environmental taxes, which could impact their competitiveness in global markets. However, a well-designed green tax policy could mitigate these risks by gradually increasing tax rates and offering incentives for industries to transition to more sustainable practices.

2. Environmental Benefits of Green Taxation: The environmental impact of green taxation is perhaps its most immediate and measurable benefit. Carbon taxes, for example, directly target greenhouse gas emissions by making it more costly to emit CO_2. This provides a strong financial incentive for industries to adopt cleaner technologies and reduce their overall emissions. Countries like Sweden and Finland, which have implemented high carbon tax rates, have successfully reduced their carbon emissions while maintaining steady economic growth.

Green taxes also contribute to more efficient use of natural resources by discouraging overconsumption and waste. Taxes on single-use plastics, landfill waste, and other pollutants encourage recycling, reduce waste generation, and promote the circular economy. In the long term, this leads to less environmental degradation and greater conservation of natural resources, which are critical for sustaining future economic growth.

In summary, green taxation serves as a powerful tool that not only stimulates economic restructuring towards sustainability but also generates significant environmental benefits. By adopting a well-balanced approach, governments can ensure that the transition to a greener economy is economically viable and socially equitable.

Abstract

This article discusses the importance of ensuring environmental safety in educational organizations. Thus, the operation of facilities is primarily associated with ensuring a safe environment for users of facilities – whether they are students, teachers, employees, legal representatives of students of an educational organization. As important as the cleanliness, order and level of the educational program being implemented, for facility planners, the safety of people should always be a top priority.
Maintenance of objects is connected, first of all, with the provision of safe conditions for users of objects, whether they are students, teachers, employees, legal representatives of students of an educational organization. As important as the cleanliness, order and level of the educational program being implemented, for facility planners, the safety of people should always be a top priority. Thus, while it can be difficult to define what exactly constitutes a «safe» environment, it is fair to say that providing a safe environment is a core component of effective educational facility management. The role of facility managers in building safety has changed in recent years. One of their main responsibilities now is to oversee the implementation of the numerous environmental regulations that govern educational institutions and their surroundings, as well as to verify compliance with many rules and laws. Thus, the successful management of the environment of an educational organization has gone far beyond the capabilities of one person.

Keywords: ecology, education, safety, economy, health protection

I. Introduction

Maintenance of objects is connected, first of all, with the provision of safe conditions for users of objects, whether they are students, teachers, employees, legal representatives of students of an educational organization. As important as the cleanliness, order and level of the educational program being implemented, for facility planners, the safety of people should always be a top priority. Thus, while it can be difficult to define what exactly constitutes a «safe» environment, it is fair to say that providing a safe environment is a core component of effective educational facility management. The role of facility managers in building safety has changed in recent years. One of their main responsibilities now is to oversee the implementation of the numerous environmental regulations that govern educational institutions and their surroundings, as well as to verify compliance with many rules and laws. Thus, the successful management of the environment of an educational organization has gone far beyond the capabilities of one person.

II. Metods and materials

In this study, such research methods as description, comparison, comparison are used.

Environmental regulations designed to protect people or the environment are many and varied and may seem overly complex to the uninitiated reader. However, most environmental safety regulations require only minimal monitoring and enforcement efforts unless a problem is identified.

III. Results

The first step in complying with environmental regulations is to be aware of their existence, purpose, applicability, and requirements. Much of this information is available from regulators, professional associations, and through on–the–job training. Obtaining this information may not always be costly, but requires significant experience, either paid or professional. In any case, compliance with environmental safety rules pays off compared to the alternative – the possible occurrence of serious problems with indoor air, leakage of underground tanks, contaminated drinking water, or other serious incidents related to the safety or health of the environment.

Measures to improve the environmental situation in educational institutions: garbage control, educational activities, saving water, fuel and electricity, refusing to use plastic bags and various disposable goods, proper use of the bin. In Russia, the Federal Law on Education in the Russian Federation was adopted, where Article 41 protecting the health of students states that protecting the health of students includes: promotion and training in healthy lifestyle skills, labor protection requirements; organization and creation of conditions for the prevention of diseases and the improvement of students, for their physical education and sports; the passage by students in accordance with the legislation of the Russian Federation of periodic medical examinations and medical examinations; prevention and prohibition of smoking, the use of alcoholic, low–alcohol drinks, beer, narcotic drugs and psychotropic substances, their analogues and other intoxicating substances; carrying out sanitary and anti–epidemic and preventive measures.

Also important is the adoption of the Federal Law of the Russian Federation of December 29, 2010 N 436–FZ «On the protection of children from information that is harmful to their health and development». Educational institutions play a crucial role in instilling discipline and ensuring environmental safety, so you need to pay attention to internal rules. Thus, educational institutions are directly responsible for creating conditions conducive to quality teaching and learning. Faculty planning safety in control engineering and technology must have an understanding of health and safety, as well as risk assessment in the field of electronics and control technology. Educational organizations today develop, implement and manage health and safety policies and procedures approved by the Board of Trustees. These rules and procedures are expected to be followed in addition to the implementation of the recommendations. Before working with students, educators need to conduct an initial risk analysis of the manufacturing process to identify hazards. The role and policy of the leadership of the educational institution in the prevention of unwanted injuries and diseases that can lead to a deterioration in human health or functionality as a result of exposure to occupational hazards, as well as its role in identifying unsafe practices and addressing safety issues in the workplace, is important

Management should be responsible for the implementation of safety and health programs in the workplace, and employers must comply with its rules. Management should establish safety and health programs under which facilities and institutions should prepare their environmental, health and safety program, provide the necessary training for their employees and personnel, conduct inspections, tests, monitoring and auditing, and establish a registration system and record keeping for these events. Management should develop occupational safety programs, according to which enterprises and organizations should organize the following (Table 1).

Table 1: *Development of a labor protection program in education*

№	Content
1	To prepare programs for environmental protection, health and safety
2	To provide the necessary training for its employees to carry out inspections, tests, monitoring and auditing
3	To create a system for registering and keeping records of these activities

Source: developed by the authors based on the materials [1-15]

Management is responsible for establishing and enforcing federal and state inspectors, organizing public education and advisory forums and workshops, and ensuring safety information materials are available.

Environmental safety is divided into internal programs for labor protection and health, environmental control.

Personal injuries and illnesses resulting from operations and situations related to study, work, interfere with a person's ability to work productively. An injured worker bears the burden of medical expenses and loss of wages. This also leads to economic losses for the company and the state.

Environmental management in education is a special aspect related to the management and proper disposal of pollutants and other sources of threat to the environment. Environmental control includes engineering and administrative decisions to minimize the impact of hazards. Examples of general environmental controls for facilities: safety color codes for pipes and cans, hazard labeling, provision of safety signs (danger, caution and warning signs), blocking/labeling, provision of sanitary facilities.

Hazard Elimination – Complete hazard elimination is the most preferred and effective solution for controlling risks and hazards. Substitution – Reduce manual stress on tools with power tools, reduce heavy objects to light ones, replace a harmful chemical with another chemical that is less or not hazardous, such as lead–free paint, natural pesticides, aqueous detergent solutions. Engineering controls are the design of systems or the modification of an existing circuit or process that will reduce exposure to hazards. Process control – electric motors instead of diesel engines, wet drilling instead of dry drilling, automation and remote control Isolation or enclosure are physical barriers that keep risk and worker from coming into contact with each other. Ventilation – removes or dilutes air pollutants to avoid dispersion in workplaces. Administrative controls are working practices and standard operating procedures that can change how and when work is done.

Restriction of access, planned maintenance of equipment, rotation of work to limit impact. Personal Protective Equipment (PPE) – PPE is the last line of defense, but it should not be the only method of reducing exposure. PPE includes eye protection, face shields, shoes and gloves. Chemical safety is another environmental safety issue that primarily focuses on ensuring the proper storage, use and disposal of hazardous chemicals. Businesses need to be aware of chemical safety regulations as it not only saves lives and saves the environment. Educational institutions should establish procedures necessary for identifying hazards in the educational and workplace and assessing existing risks for routine, non–routine and potential emergencies. After identifying hazards and risks, it is necessary to assess the level of exposure to students and employees, existing control measures, develop a plan to eliminate hazards and risks, conduct periodic inspections and identify new threats. Employee participation in an EHS program is integral to its successful implementation, from EHS planning, setting goals and objectives, risk and hazard reporting, monitoring, to incident investigation. Safety training for employers and employees.

Managers must be trained and informed about safety concepts, their role in its implementation and their responsibility to protect the well–being of workers at all times. All employees should be trained in how the safety program works, their participation in it, and the skills to identify and recognize risks and hazards. Hazard prevention and control. Controls should first follow a hierarchy of engineering, then safe practices, administrative controls, and personal protective equipment. Evaluation and improvement Implemented controls should be periodically evaluated to verify their effectiveness. A program monitoring process should be established along with indicators used to check program implementation and identify opportunities for improvement.

The Hazardous Waste Management and Emergency Response Guide focuses on the management of hazardous and hazardous substances and wastes and the provision of emergency response. It is designed for workers who are directly exposed to danger and are responsible for storing, cleaning, handling and disposing of hazardous materials [1-15].

IV. Conclusion

Thus, the environmental safety of educational institutions is determined by the guidance, policies and practices applied to ensure that the environment is free from hazards that guarantee the safety and well–being of staff and students, as well as the prevention of accidental environmental damage. Surrounding areas include industrial facilities, work areas and laboratories. Environmental safety is a critical issue for any industrial activity, as negligence and non–compliance increase the risk of injury, illness and accidental releases to the environment. Poor indoor air quality can affect student and teacher performance by causing eye, nose, and throat irritation, fatigue, headache, nausea, sinus problems, and other mild or serious illnesses.

Abstract

The article is devoted to the issues of cleaning and maintaining the channels of the reclamation drainage system in a working condition. During the study, the general condition and characteristics of the reclamation channels of the drainage network were analyzed, as a result of which it was concluded that the volume of sediments, siltation and vegetation in the channels increased in the absence of maintenance operations, which in turn leads to a decrease in the channel capacity and flooding of agricultural fields. At the same time, the study showed that the proportion of channels in the drainage network, sediment volumes in most channels range from 0.02 to 0.10 m3 per 1 m length, which corresponds to a chip thickness of 5...15 cm. In the course of the work, factors preventing the maintenance of the design depth of drainage channels were identified, which are mainly associated with the increasing volume of sediment and siltation in the absence of canal maintenance operations. The study proposes designs of working bodies of channel cleaning machines moving on rigid guides strictly in a straight line along the axis of the channel, which are capable of cleaning channels both with fixed bottoms and slopes, and without their attachment. The analysis of the stress state of the elements of the new working bodies is presented. In conclusion, the study presents the main conclusions and results of the work carried out.

Keywords: drainage channels, sediments, siltation, vegetation

I. Introduction

Cleaning of reclamation channels of the drainage network is very relevant, since it allows us to solve the important task of ensuring the normal functioning of the entire reclamation system as a whole.

During operation, sediments, siltation, herbaceous and shrubby vegetation appear on the bottom and slopes of reclamation channels, which definitely affects the operation of the system: firstly, the channel capacity is disrupted; secondly, the design depth of the channel, calculated for a specific agricultural field on which a particular crop is grown with a certain drainage rate, it becomes smaller and the site is subject to flooding and an increase in the groundwater level according to the depression curve

All this affects the yield of the agricultural field. The main tasks of agricultural land reclamation are to provide the cultivated crop with optimal water, air, nutrient and thermal conditions. If there is a lot of water in the field, then the plant may die from excess water and lack of air, or another situation is possible during a drought, the plant may also die from lack of moisture.

Therefore, it is important to maintain the design depth of drainage channels by performing their timely cleaning from sediments, siltation, herbaceous and shrubby vegetation. The most advanced drainage systems with open channels are currently operating in the Netherlands.

On the territory of the Russian Federation, this is the Kaliningrad Region. Periodic cleaning operations within the framework of canal maintenance operations increase the service life of canals before major repairs. The channels are cared for by various channel cleaning machines, including continuous and periodic machines. Trapezoidal channels have become the most widespread in reclamation drainage systems [1–4].

They can be made in an earthen body with or without mounting slopes. The slopes are fixed on channels with weakly bearing soils, on which it is possible for the upper parts to slide to the bottom of the channel. Drainage channels with fixed bottoms and slopes account for about 20% of all drainage channels [5–6]. Their lesser importance is explained by the large lengths of the channels as a whole. The main characteristics of the drainage channels are presented in Table 1.

Table 1: *Average values of the main characteristics of drainage channels.*

Characteristic	Value
Channel depth	before 2,5 –3,0 m
Channel width along the bottom	0,4; 0,6; 0,8; 1,0; 1,2 m
Channel width at the top	8, 10; 12; 14 m
Laying of slopes	1:1; 1:1,15; 1:5

The purpose of the work is to determine the characteristics and condition of reclamation drainage channels with the proposal of methods and means for their cleaning and restoration.

Materials and methods of research. The research materials were reports on the study of the condition of drainage channels, reports on the use of the PP–303 channel cleaning machine developed at the Department of Reclamation and Construction Works, as well as the Field experimental station of the Timiryazev Academy channel cleaner OKN–0.5 of the Kohanovsky Excavator Plant (now JSC Amkodor) purchased for canal cleaning.

To study the condition of drainage channels, the following methods were used: observation of channels, comparison of the condition of sections of channels of the reclamation system, experiment to determine the stability of channels, measurement of geometric parameters of the operated channel and their comparison with design data, practical physical modeling of the channel and working bodies of channel cleaning machines.

Observation of the operation of reclamation drainage channels of the reclamation system of the Field Experimental Station RGAU–MSHA named after K. A. Timiryazev during the study period of 2–4 years shows that over time sediments, siltation, herbaceous and shrubby vegetation appear on the bottom and slopes of the channels.

The distribution of sediments and siltation is formed unevenly, their greater accumulation is observed at the junction of one channel with another or at the locations of drainage pipes. Grassy vegetation, unlike sediments, is more evenly distributed along the slopes of the canal [7]. In the absence of constant maintenance of the channels without their repairs, the amount of sediment on the bottom and slopes of the channels may increase. At the same time, the cross–sectional area of the channel is violated, most often it decreases, which leads to a decrease in the channel capacity. This is only the visible part of the state of the channels at this stage.

For a clearer understanding of the problem of sediment and siltation layers increasing over time, it is necessary to find out the original reasons for the construction of canals. Drainage channels are necessary to drain excess water during the flood period. In addition, channels are necessary to maintain the drainage rate of various crops according to the depression curve.

With an increase in the amount of sediment and siltation, the groundwater level rises, while the design water level in the channel is violated. In general, in agricultural land reclamation, for the normal growth of crops, it is necessary to ensure optimal values of water, air, heat and nutrient regimes. If there is an excess of water or a lack of it, the plant may die.

In the process of cleaning channels, there may be situations when the operator of the channel cleaner uses a bucket working body to develop sediments and soils below the design water level, while reducing the drainage rate, which can lead to a lack of moisture for the cultivated crop.

Each crop grown in the drainage zone has its own drainage rate (cm from the surface): perennial grasses for hay, flax 50–60; artificial pasture 65–75; legume–cereal feed mixtures, spring grains (oats, barley), winter rye 60–75; vegetable crops, fodder root crops, hemp 75–95.

On drainage reclamation systems, trapezoidal channels are mainly found in the earthen body without fixing the slopes. Bucket channel cleaners are mainly used to clean sediments and siltation of the bottom and slopes of such channels.

Currently, such a machine is the channel cleaner OKN–0.5 (mounted channel cleaner). Not all reclamation companies have this channel cleaner on their balance sheet, therefore, general–purpose single–bucket excavators with working equipment are often used to restore channels, a reverse shovel with a widened bucket [8, 9]. As is known, such positional machines from the berm of the channel develop sediments on the bottom and slopes in the transverse direction to the axis of the channel.

The situation is different when cleaning channels with a fixed bottom. The use of bucket channel cleaning machines for transverse digging is excluded here, otherwise the fastening elements of the bottom and slopes will be destroyed.

To solve such a set of tasks, the Department of Reclamation and Construction Machinery developed a channel cleaner with a longitudinal movement of the PP–303 bucket along the axis of the channel (channel repairer) for cleaning channels up to 3 m deep (Fig. 2). The main purpose of a rectangular bucket is cleaning the fixed bottom when other types of machines are not applicable. At the same time, this machine can be used to clean channels without fixing the bottom and slopes. In this case, a replaceable trapezoidal bucket is used.

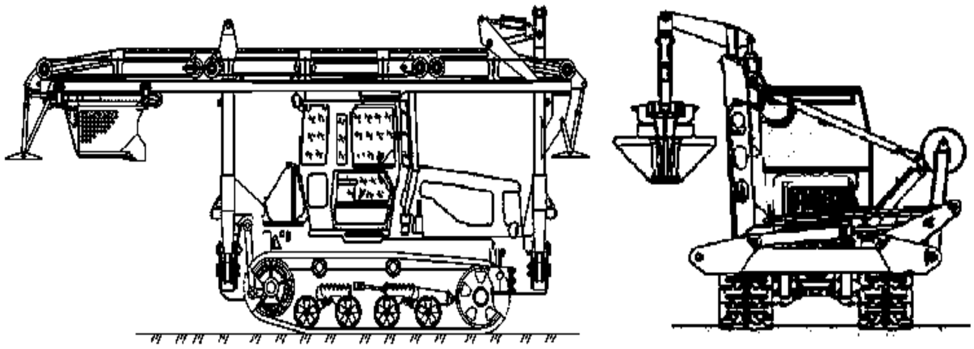

Figure 1: *Channel cleaner PP–303 (side and front views)*

The development and application of new working bodies of channel cleaners with increased capacity requires verification calculations on the strength of structural elements, as well as the stability of the entire machine during the working operation.

Strength calculations are reduced to determining the coefficient of safety margin, for this purpose various computer graphics programs such as Compass, Inventor Pro and others are used. These programs contain modules for conducting strength calculations using the finite element method (FEM).

The essence of this calculation method is to create a three–dimensional structure from a particular material, break it down into finite elements (i.e., create a finite element grid), check them at specified supports and loads. The margin of safety obtained in this way should be in the range from 1.5 to 2.0 units.

Research results and discussion. The results of the strength calculation of one of the parts of the channel cleaning machine are shown in Fig. 2.

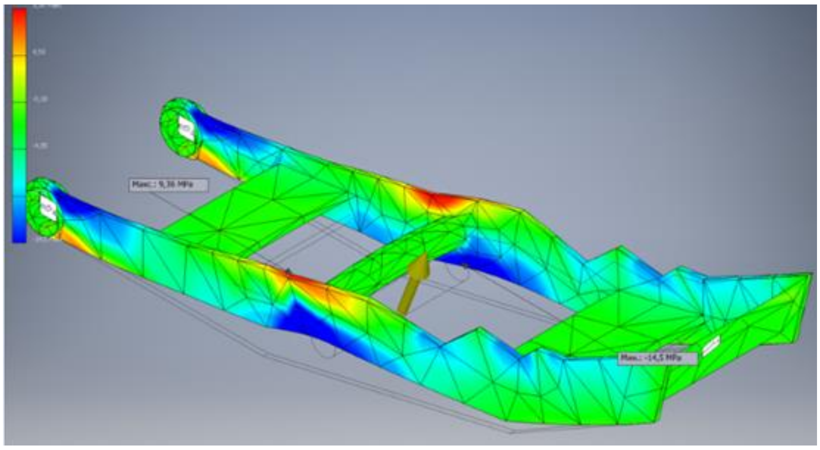

Figure 2: *Analysis of the stress state of the additional element to the channel cleaner bucket*

In cases where the safety factor turns out to be close to the minimum values of the permissible range, for example, 1.51, it is advisable to carry out a refined strength calculation, in which, in order to obtain real values of the safety margin, the dimensions of the finite elements are set much smaller [10-15].

Often, with refined calculations, the values of the safety factor are less than 1.5 – this indicates that the structure does not withstand the specified loads. In the example under consideration, this value is within the permissible limits of 1.9 and therefore there is no need for a refined calculation.

II. Conclusion

According to the conducted studies of the state of reclamation channels, their quantitative, qualitative and geometric characteristics have been clarified. For cleaning channels of a trapezoidal profile, bucket channel cleaners of transverse digging or general construction excavators with replaceable working equipment are most suitable. A reverse shovel with a widened bucket.

For drainage channels with a fixed bottom, it is advisable to use channel cleaners with a rectangular bucket on rigid guides. To clean channels in an earthen body without fixing the bottom and slopes, it is also advisable to use the construction of rigid guides, but with a trapezoidal bucket.

The strength calculations of the elements of the working equipment of the proposed channel cleaner showed a sufficient margin of safety when working with a trapezoidal bucket with increased capacity.

Abstract

The study emphasizes the importance of policy interventions aimed at enhancing human capital, including increased funding for education, promotion of public health initiatives, and fostering a culture of innovation. The findings underscore the necessity of viewing human capital as a long-term investment rather than a short-term expenditure. This perspective shifts the focus towards sustainable economic strategies that prioritize human capital development as a pathway to achieving inclusive and sustainable growth. In conclusion, the paper provides practical recommendations for governments and private sectors on how to effectively invest in human capital to foster economic development. By doing so, policymakers can create a more resilient economy that is better equipped to face future challenges while ensuring improved quality of life for all citizens. In conclusion, education is a fundamental driver of positive labor market outcomes, influencing employment rates, income levels, and job satisfaction. By investing in education and ensuring equitable access to quality learning opportunities, governments can enhance the skills of their workforce, promote economic growth, and contribute to a more prosperous and equitable society.

Keywords: economic growth, innovation, sustainable development, policy interventions, emphasizes

I. Introduction

Currently, countries and regions worldwide face the dual challenge of fostering economic growth to meet basic material needs while improving the overall quality of life for their populations. In this context, the urgency of protecting the environment and utilizing natural resources sustainably has become increasingly evident. A key priority for many states is the preservation of limited resources to safeguard the well-being of future generations.

In the late 1980s, there was a significant shift in perspectives on the human impact on the environment, the environmental consequences of resource exploitation, and the interconnections between environmental issues, poverty, and economic development. This shift led to the emergence of a new approach to addressing environmental and economic concerns—an approach that balances competing objectives, such as environmental conservation, economic growth, and the satisfaction of human needs. This concept became known as "sustainable development."

The principle of sustainable development rests on the idea that a nation's prosperity depends not only on its economic wealth but also on a healthy environment and livable conditions. Economic progress is deemed meaningless if it exacerbates environmental risks. Irreversible environmental damage or the depletion of natural resources today restricts future generations' ability to access these resources, undermining their capacity to meet their own needs. Thus, sustainable development seeks to harmonize economic and environmental priorities to ensure equity across generations.

Although the goals of sustainable development may seem contradictory in the short term, they offer greater long-term benefits. For instance, economic growth may initially appear to conflict with resource conservation, but responsible resource management ensures their availability for future sustainable growth. As a result, sustainable development has become a widely discussed and adopted concept in modern environmental and economic discourse.

Numerous definitions of sustainable development exist, most of which emphasize the need to balance economic growth with its social, environmental, and economic impacts. A widely recognized definition comes from the Brundtland Report, which describes sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs."

II. Methods

The concept of sustainable development is implemented through a variety of methods and strategies aimed at balancing economic growth, environmental protection, and social well-being. These methods can be broadly categorized into the following areas:

1. Policy and Governance

Environmental Regulations and Legislation: Establishing laws and policies to control pollution, manage waste, and protect natural resources.

Sustainable Development Goals (SDGs): Aligning national and regional policies with international frameworks such as the UN's SDGs.

Incentives for Green Practices: Providing tax benefits, subsidies, or grants for businesses and individuals that adopt sustainable practices.

2. Sustainable Resource Management

Efficient Resource Use: Implementing practices that minimize waste and maximize the utility of natural resources.

Renewable Energy Adoption: Transitioning from fossil fuels to renewable energy sources like solar, wind, and hydro.

Circular Economy: Promoting recycling, reuse, and designing products with longer lifespans to reduce resource depletion.

3. Technological Innovation

Clean and Green Technologies: Developing and deploying technologies that reduce environmental impacts, such as carbon capture, water purification systems, and energy-efficient machinery.

Smart Cities: Using technology to optimize urban planning, transportation, and energy use while minimizing environmental harm.

4. Community Engagement and Education

Awareness Campaigns: Educating the public about sustainable practices and encouraging behavior change at the individual and community levels.

Local Involvement: Empowering communities to participate in decision-making processes related to sustainability initiatives.

5. Economic Instruments

Carbon Pricing: Implementing carbon taxes or cap-and-trade systems to reduce greenhouse gas emissions.

Green Investments: Encouraging investments in sustainable industries through green bonds or socially responsible investing.

Eco-Labeling: Certifying products that meet sustainability standards to guide consumer choices.

6. International Cooperation

Global Agreements: Participating in treaties and agreements like the Paris Climate Agreement to collectively address global challenges.

Technology Transfer: Sharing sustainable technologies and practices between developed and developing nations.

7. Monitoring and Assessment

Sustainability Metrics: Measuring progress through indicators such as the Environmental Performance Index (EPI) or Gross Domestic Product (GDP) adjusted for environmental factors.

Impact Assessments: Conducting environmental and social impact assessments for projects and policies to ensure alignment with sustainability goals.

By integrating these methods, sustainable development aims to create systems that support long-term economic, environmental, and social health.

III. Results

Another definition of sustainable development is "Caring for the Earth," which emphasizes an approach aimed at "improving the quality of human life while living within the carrying capacity of supporting systems" [4]. Sustainable development involves using limited resources and impacting the environment in ways that neither degrade their condition nor reduce their utility for future generations.

Early economic theorists suggested that economic development could coexist with environmental protection policies while fostering innovation and generating profit. In 1920, Arthur Pigou, in his work The Economics of Welfare, identified a disparity between private marginal costs and benefits and social marginal costs and benefits, which he referred to as externalities [5]. Externalities are the unintended side effects of economic activity, whether costs or benefits, not reflected in the prices of goods or services. To address negative externalities, Pigou proposed a tax on activities that produce them, set at a rate to equalize private and social costs. This tax, known as the Pigovian tax, would make market prices more accurately reflect the true costs and benefits of economic activities. However, implementing such a tax proved challenging in practice, especially as environmental problems grew both regionally and globally. It became evident that market mechanisms alone were insufficient to allocate environmental resources effectively or to assign proper monetary value to their destructive use.

Building on Pigou's arguments, Michael Porter and Claas van der Linde theorized that environmental pollution could be seen as a sign of inefficient resource use. They concluded that improvements in production processes that reduce environmental pollution are essential for reconciling ecological and economic interests [6]. Their research demonstrated that competitive advantages are directly linked to innovation capacity, and strict environmental regulations can stimulate innovation, leading to greater competitiveness and profitability [6].

The environmental dimension of sustainable development focuses on protecting ecosystems, air quality, and the integrity and resilience of natural resources. It also addresses how technologies can shape a "greener" future, highlighting that advancements in technology and innovation are key to sustainability and to mitigating potential harm caused by scientific and technological progress.

Since the late 20th century, the concept of a "green economy" has gained traction as an innovative technological model and a critical factor in achieving environmentally sustainable development. In light of pressing global challenges such as climate change, population growth, environmental pollution, and inefficient resource use, countries need to adopt technologies and economic approaches that minimize environmental harm and conserve resources. Sustainable development thus requires reducing environmental damage and considering the needs of future generations, supported by policies at both international and national levels [7].

For instance, the European strategy for "smart, sustainable, and inclusive growth" identifies key drivers of economic strength: *smart growth* (developing a knowledge- and innovation-based economy), *sustainable growth* (promoting a more resource-efficient, green, and competitive economy), and *inclusive growth* (fostering a high-employment economy ensuring social and territorial cohesion). This strategy includes sections on the rational use of natural resources, energy sources, and the benefits of renewable energy adoption [8].

Countries need well-defined action plans and monitoring indicators for sustainable development and "green" growth. Transitioning to green technologies should align global trends toward improving human well-being and social equity while reducing ecological risks. Success in this transition depends on increased public investment, ecological taxes, and regulatory measures to mitigate the environmental footprint of industries. It also relies on enhancing environmental protection laws [9].

Studies show that adopting green technologies, particularly green energy, is a priority for achieving sustainable development. Renewable energy sources and their associated technologies are recognized globally as an eco-friendly alternative to fossil fuels, which contribute to environmental pollution. The degree to which green energy development influences technologies, industries, and applications determines the extent of sustainability achieved. Negative impacts on industrial, technological, social, and economic development are partially or entirely mitigated throughout the transition to green energy and technologies. This makes sustainable energy strategies both preferable and increasingly adopted.

Strategies based on green energy can significantly contribute to the economies of countries that prioritize accelerated development of alternative renewable energy sources (e.g., wind, solar, tidal, and biomass energy). Governments should encourage investments in clean energy solutions and progress in replacing fossil fuels with environmentally friendly energy to secure a cleaner and more sustainable future [10].

IV. Discussion

The growth of the global economy leads to an increase in energy consumption, making it increasingly important to produce energy with minimal costs while reducing environmental pollution. According to expert forecasts, by 2035, renewable energy sources will account for more than half of global electricity production. However, as of today, energy production in some countries often falls short of environmental safety standards and resource efficiency requirements. In Russia, for instance, the current level of "green" energy utilization remains insufficient. This situation is not confined to the energy sector; the development of ecological technologies across various industries in the country is uneven. While developed nations have already launched campaigns to promote clean technologies, this process is only beginning in Russia. This lag is largely due to insufficient demand from businesses and consumers. Nonetheless, a growing trend of increased demand and investment, particularly in alternative energy and energy conservation, has recently emerged.

"Green" growth has the potential to reduce poverty, mitigate vulnerability to climate change, foster economic growth, and enhance energy security. Innovative processes and scientific knowledge are fundamental to ensuring the rational use of natural resources [12]. The transition to renewable energy aims to reduce the negative impact on the planet's energy balance, a critical component of the sustainable development framework for national economies. This shift has driven the active development of renewable energy both internationally and within Russia. Moreover, there is significant potential for creating and implementing environmental technologies in Russia, provided that new incentive tools are introduced as part of the state's science and technology, investment policies, and the development of the green finance market [13].

Each region in Russia has the potential to develop specific types of energy. For example, the natural and climatic conditions of the Republic of Kalmykia are well-suited for constructing power generation facilities utilizing renewable energy sources, particularly wind energy. At the national level, initiatives to provide the region with affordable electricity include investment projects for building new generation facilities. In December 2020, the Salynskaya and Tselinskaya wind power plants—the largest generation facilities in the region—were commissioned in Kalmykia [14].

Global experience demonstrates the successful transition of countries toward sustainable development through the creation and implementation of "green" technologies across various economic sectors. These efforts are reflected in the policies of modern states. By studying international practices, Russia can develop its own approach to advancing "green" energy and renewable energy generation that can compete with traditional energy systems. Such an approach would contribute to environmental protection and the rational use of natural resources.

In conclusion, the transition to sustainable development, underpinned by the principles of "green" growth and renewable energy, is crucial for addressing global environmental and economic challenges. By adopting innovative technologies and fostering the use of renewable energy, nations can reduce environmental pollution, mitigate the effects of climate change, and ensure long-term economic and energy security.

Russia, despite its current lag in the development of ecological technologies and renewable energy, has significant potential to harness its natural and regional resources for sustainable growth. Lessons from international experience highlight the importance of comprehensive state policies, investment incentives, and green financing in accelerating this transition. The development and implementation of renewable energy technologies, such as wind and solar energy, could not only meet current energy needs but also preserve resources for future generations.

Ultimately, achieving sustainable development requires a balanced approach that integrates economic growth, environmental conservation, and social equity. By prioritizing these goals and actively promoting "green" initiatives, Russia and other nations can pave the way for a more sustainable and prosperous future.

Abstract

This study explores the pivotal role of human capital in driving economic development at both regional and national levels. Human capital, which encompasses the knowledge, skills, experience, and health of the workforce, is increasingly recognized as a crucial determinant of economic growth.

This paper begins by defining human capital and its components, highlighting how education, vocational training, and health contribute to the overall productivity of the labor force. The analysis delves into various factors that enhance human capital, including access to quality education, lifelong learning opportunities, and healthcare services. It examines the correlation between human capital investment and economic performance indicators such as GDP growth, labor productivity, and innovation rates. By reviewing existing literature and case studies from different countries, the study illustrates how regions with higher levels of human capital tend to experience faster economic growth and improved living standards. Furthermore, the research addresses the challenges and barriers to human capital development, particularly in developing countries, where inadequate educational systems and limited access to healthcare can hinder progress.

The study emphasizes the importance of policy interventions aimed at enhancing human capital, including increased funding for education, promotion of public health initiatives, and fostering a culture of innovation. The findings underscore the necessity of viewing human capital as a long-term investment rather than a short-term expenditure. This perspective shifts the focus towards sustainable economic strategies that prioritize human capital development as a pathway to achieving inclusive and sustainable growth. In conclusion, the paper provides practical recommendations for governments and private sectors on how to effectively invest in human capital to foster economic development. By doing so, policymakers can create a more resilient economy that is better equipped to face future challenges while ensuring improved quality of life for all citizens.

In conclusion, education is a fundamental driver of positive labor market outcomes, influencing employment rates, income levels, and job satisfaction. By investing in education and ensuring equitable access to quality learning opportunities, governments can enhance the skills of their workforce, promote economic growth, and contribute to a more prosperous and equitable society.

Keywords: economic growth, education, workforce productivity, health, innovation, sustainable development, policy interventions, labor force

I. Introduction

In an increasingly globalized and competitive economy, the significance of human capital has emerged as a critical factor in driving economic development and growth. Human capital refers to the collective skills, knowledge, experiences, and health of individuals within a workforce. Unlike physical capital, which comprises tangible assets such as machinery and infrastructure, human capital is inherently intangible yet immensely influential in determining a nation's economic performance.

The relationship between human capital and economic growth has garnered substantial attention from researchers, policymakers, and economists alike. As technological advancements reshape industries and the demand for skilled labor continues to rise, the quality of human capital becomes a pivotal determinant of a country's ability to innovate, compete, and sustain long-term economic growth. Nations that prioritize investments in education, healthcare, and training often experience higher productivity levels, increased innovation, and improved standards of living.

Despite the evident importance of human capital, disparities in its development persist across different regions and countries. Factors such as access to quality education, healthcare services, and economic opportunities vary significantly, leading to unequal economic growth trajectories. Developing nations, in particular, face unique challenges in harnessing human capital due to systemic issues such as inadequate educational infrastructure, high rates of poverty, and limited access to healthcare. Consequently, addressing these challenges is essential for fostering inclusive and sustainable economic growth.

This study aims to explore the multifaceted role of human capital in economic development by analyzing the factors that contribute to its enhancement. It will delve into the significance of education and training in building a skilled workforce, the impact of health on productivity, and the importance of lifelong learning in adapting to a rapidly changing economic landscape. Furthermore, the study will examine the role of government policies and private sector initiatives in fostering human capital development.

By providing a comprehensive analysis of these elements, this paper seeks to contribute to the ongoing discourse on economic development strategies, emphasizing the need for a robust human capital framework. Ultimately, the findings will highlight that investing in human capital is not only a moral imperative but also a strategic necessity for achieving sustainable economic growth and improving the overall quality of life for individuals and communities.

II. Methods

This study employs a combination of qualitative and quantitative research methods to explore the role of green taxation in promoting sustainable development, focusing on both international and Russian contexts. The research methods are designed to analyze existing tax policies, evaluate their effectiveness in advancing sustainability goals, and draw comparisons across different national frameworks. The following three methods were used:

1. **Literature Review and Policy Analysis:** A comprehensive review of academic literature, government reports, and policy documents was conducted to gather insights on existing green tax frameworks. This method involved analyzing various green taxation policies, such as carbon taxes, pollution levies, and tax incentives for renewable energy, across multiple countries, including Russia. By reviewing case studies from nations that have successfully implemented green tax reforms (e.g., the European Union, Sweden, and Germany), this analysis identified key trends, challenges, and best practices in designing and executing tax policies that contribute to sustainable development. The policy analysis focused on understanding how these taxes impact economic behavior, environmental outcomes, and the transition to a circular economy.

2. **Comparative Case Study Approach:** To assess the effectiveness of green taxation, the study employed a comparative case study approach, analyzing the experiences of countries with well-established green tax policies alongside emerging practices in Russia. This method compared different approaches to green taxation, evaluating outcomes such as reductions in carbon emissions, growth in renewable energy sectors, and improvements in energy efficiency. Countries selected for comparison included those with advanced green tax systems, such as Sweden,

Germany, and the United Kingdom, as well as countries at earlier stages of implementation, like Russia. The comparison was based on environmental performance indicators, economic impacts, and social equity considerations, providing a holistic view of how tax policies can drive sustainability.

Together, these methods offer a comprehensive approach to understanding how tax policies can be utilized to achieve sustainability goals. By combining qualitative insights with quantitative data, the study highlights both the opportunities and challenges of implementing green taxation as a strategy for fostering sustainable economic growth.

III. Results

The analysis of human capital's role in economic development yielded several significant findings that underscore its impact on economic growth and productivity. A strong positive correlation was found between educational attainment and economic growth rates. Countries with higher levels of education, particularly in science, technology, engineering, and mathematics (STEM) fields, demonstrated increased labor productivity and innovation. Moreover, investment in early childhood education was shown to yield substantial long-term benefits, enhancing cognitive skills and creating a solid foundation for lifelong learning. Regions that prioritized early education experienced accelerated economic growth compared to those that did not.

Health also emerged as a crucial component of human capital, directly influencing workforce productivity. Healthier populations tend to have lower absenteeism rates, increased energy levels, and higher engagement in their work, all of which contribute to overall economic output. The research indicated that access to quality healthcare services was linked to improved worker performance. Countries that invested in their healthcare systems saw significant reductions in healthcare costs associated with lost productivity, leading to increased overall economic performance.

Innovation was identified as another key area influenced by human capital. The research indicated that a well-educated and healthy workforce is better positioned to drive innovation. Regions that fostered an environment conducive to research and development (R&D) and entrepreneurship reported higher rates of technological advancements and economic diversification. Investment in human capital not only enhanced the skills of the workforce but also encouraged collaboration between educational institutions and industries, resulting in innovative solutions to complex economic challenges.

Effective government policies aimed at enhancing human capital were identified as critical to achieving sustainable economic growth. Countries that implemented comprehensive education and health policies, including vocational training programs and public health initiatives, experienced higher GDP growth and improved social outcomes. The study highlighted successful case examples where targeted investments in human capital led to significant economic transformation, particularly in emerging economies. For instance, nations that prioritized skills training and lifelong learning initiatives reported reduced unemployment rates and improved economic resilience.

Despite these positive impacts, the study also identified several challenges that hinder the development of human capital, particularly in developing regions. Inadequate educational infrastructure, socio-economic disparities, and limited access to healthcare services were notable barriers. Cultural factors and systemic issues often prevented marginalized populations from fully benefiting from educational and economic opportunities, highlighting the need for inclusive policies that address these inequities.

Overall, the cumulative effect of human capital investments was evident in the economic growth of the analyzed regions. A clear trend emerged where investments in education and health correlated with enhanced GDP growth rates and improved quality of life indicators, such as life expectancy and income levels. These findings underscore the critical role of human capital as a driver of economic growth. By investing in education, health, and innovative capacities, countries can significantly enhance their economic performance and ensure a more sustainable and inclusive growth trajectory. Policymakers are urged to prioritize human capital development as a strategic imperative for achieving long-term economic objectives.

IV. Discussion

The findings of this study illuminate the multifaceted relationship between human capital and economic development, underscoring the critical role that investments in education, health, and innovation play in driving sustainable economic growth. The strong correlation between educational attainment and economic performance reveals that a skilled workforce is not only essential for individual success but also pivotal for national prosperity. As countries increasingly compete in a globalized economy, the ability to adapt to technological advancements and market demands becomes increasingly tied to the quality of human capital. This underscores the necessity for governments to prioritize educational reforms that promote critical thinking, creativity, and technical skills, particularly in STEM fields.

The positive impact of health on productivity reinforces the notion that human capital is not solely about education but also encompasses physical well-being. Healthier workers contribute more effectively to the economy, resulting in lower healthcare costs and higher overall output. This relationship calls for integrated policies that not only invest in education but also enhance healthcare systems. By addressing public health issues, governments can ensure that their populations remain healthy and capable of contributing to economic growth. Moreover, the emphasis on preventive healthcare can lead to significant long-term economic benefits by reducing the burden of chronic diseases and enhancing workforce participation rates.

The role of innovation, as highlighted by this study, cannot be overstated. In today's rapidly changing economic landscape, countries that foster environments conducive to innovation through education and research are better positioned for economic success. Collaborative efforts between educational institutions and industries can drive technological advancements and foster entrepreneurship, creating a virtuous cycle of growth. Policymakers should encourage partnerships that promote knowledge transfer and support research initiatives that address pressing economic and social challenges.

However, while the findings demonstrate the potential benefits of human capital investment, they also reveal significant challenges that must be addressed. The disparities in access to quality education and healthcare services indicate that not all populations benefit equally from economic growth. This inequality can perpetuate cycles of poverty and limit social mobility, hindering overall economic development. Therefore, it is essential for policymakers to adopt inclusive strategies that ensure marginalized communities have access to educational and health resources. Targeted interventions, such as scholarships, mentorship programs, and community health initiatives, can help bridge these gaps and create more equitable opportunities for all.

The study also emphasizes the importance of lifelong learning as a necessary component of human capital development. In a world where job requirements are continuously evolving, the capacity for individuals to adapt and learn new skills is vital. Governments and private sectors must invest in continuous education and training programs to help workers reskill and upskill throughout their careers. Such investments will not only enhance individual employability but also improve overall workforce adaptability, making economies more resilient to shifts in the labor market.

In conclusion, the discussion highlights that human capital is a cornerstone of economic development and growth. By recognizing and addressing the complex interplay between education, health, and innovation, governments can formulate effective policies that foster a skilled and healthy workforce capable of driving sustainable economic progress. The path toward achieving these goals lies in a comprehensive approach that prioritizes human capital development, ensuring that all individuals can contribute to and benefit from economic growth. As the global economy continues to evolve, the importance of investing in human capital as a strategic imperative cannot be overstated.

Table 1: *Key aspects of the role of human capital in economic development*

Category	Factors	Impact on Economic Growth	Examples/Notes
Education	- Quality of education	- Increased productivity and innovation	Countries with higher education levels experience faster GDP growth.
	- Access to education	- Higher employment rates	Early childhood education improves long-term outcomes.
	- Vocational training	- Enhanced skills matching with labor market needs	Vocational training leads to lower unemployment rates.
Health	- Access to healthcare	- Improved worker productivity	Healthier populations have lower absenteeism.
	- Public health initiatives	- Decreased healthcare costs	Preventive healthcare reduces long-term expenses.
	- Nutrition and well-being	- Higher engagement and morale	Nutrition impacts cognitive performance and productivity.
Innovation	- Research and development (R&D)	- Economic diversification and competitiveness	Countries that invest in R&D see faster technological advancements.
	- Collaboration between sectors	- Creation of new markets and jobs	Partnerships between universities and businesses foster innovation.
	- Entrepreneurial support	- Increased startups and economic dynamism	Regions with supportive ecosystems have vibrant entrepreneurship.
Policy Interventions	- Investment in education and health	- Sustainable economic growth	Targeted policies lead to improved social outcomes.
	- Inclusive policies	- Reduction of inequalities	Programs targeting disadvantaged communities enhance access to resources.
	- Lifelong learning initiatives	- Adaptability of workforce	Continuous education prepares workers for changing job markets.

This table illustrates the interconnectedness of education, health, innovation, and policy interventions as components of human capital that collectively contribute to economic growth. Each category highlights specific factors that impact economic performance and provides examples of how these relationships manifest in different contexts. By addressing these factors through comprehensive policies, governments can effectively enhance human capital and, consequently, drive sustainable economic development.

The Influence of Education on Labor Market Outcomes

Education plays a pivotal role in shaping labor market outcomes, significantly impacting economic growth and development. A well-educated workforce is essential for fostering productivity, innovation, and overall economic competitiveness. This subsection explores the various ways in which education influences labor market outcomes, including employment rates, income levels, and job satisfaction.

One of the most direct effects of education on labor market outcomes is the correlation between educational attainment and employment opportunities. Higher levels of education typically lead to lower unemployment rates, as individuals with advanced qualifications are often more attractive to employers. In contrast, those with lower educational attainment face increased challenges in securing stable and well-paying jobs. For instance, studies have shown that individuals with a bachelor's degree or higher have significantly lower unemployment rates compared to those with only a high school diploma. This disparity underscores the critical importance of higher education in providing individuals with the skills and knowledge necessary to thrive in a competitive job market.

Moreover, education directly impacts income levels and earning potential. Data consistently indicate that individuals with higher educational qualifications tend to earn more over their lifetimes compared to those with less education. The wage premium associated with higher education reflects the added value that skilled workers bring to employers. For example, professionals in fields such as medicine, engineering, and technology often command substantial salaries due to their advanced training and specialized knowledge. This income disparity not only benefits individuals but also contributes to broader economic growth, as higher incomes lead to increased consumer spending and tax revenues.

In addition to employment rates and income levels, education also influences job satisfaction and overall career fulfillment. Research indicates that individuals with higher levels of education are more likely to report higher job satisfaction and a greater sense of fulfillment in their careers. This correlation can be attributed to several factors, including increased job responsibilities, opportunities for advancement, and the ability to engage in meaningful work. Consequently, investing in education not only enhances economic productivity but also promotes a more motivated and satisfied workforce.

Furthermore, education fosters social mobility, enabling individuals from disadvantaged backgrounds to improve their economic circumstances. Access to quality education can break the cycle of poverty, providing opportunities for upward mobility and reducing income inequality. Governments and organizations that prioritize equitable access to education contribute to the development of a more skilled workforce, thereby enhancing economic resilience and social cohesion.

Despite the clear benefits of education on labor market outcomes, significant disparities persist in access to quality education across different regions and demographics. Factors such as socio-economic status, geographic location, and systemic inequalities can hinder educational attainment for marginalized groups. Addressing these disparities through targeted policies and investments is essential for creating a more inclusive labor market and maximizing the economic potential of all individuals.

In conclusion, education is a fundamental driver of positive labor market outcomes, influencing employment rates, income levels, and job satisfaction. By investing in education and ensuring equitable access to quality learning opportunities, governments can enhance the skills of their workforce, promote economic growth, and contribute to a more prosperous and equitable society.

Abstract

The green economy, focused on sustainable development and reducing environmental impacts, has become an increasingly attractive area for investment. This paper provides an in-depth analysis of the opportunities and risks associated with investing in the green economy. Key sectors examined include renewable energy (solar, wind, and bioenergy), sustainable agriculture, electric vehicles, energy efficiency technologies, waste management, and carbon capture solutions. The analysis explores how these sectors are benefiting from global trends such as climate change mitigation policies, corporate commitments to carbon neutrality, technological innovations, and growing consumer demand for sustainable products and services. On the opportunity side, investors stand to gain from significant market growth, government incentives, and regulatory frameworks such as carbon pricing and renewable energy targets. For example, renewable energy is becoming more cost-competitive with fossil fuels, and electric vehicle sales are projected to rise as countries phase out internal combustion engines. Green bonds and environmental, social, and governance (ESG) criteria have also opened new financing channels for green projects, providing investors with diversified portfolios that align financial performance with positive environmental impact.

Keywords: green technologies, sustainable agriculture, electric vehicles, carbon capture, regulatory risks, green bonds

I. Introduction

The transition to a "green" economy and its models, global divestments in the world (redistribution of investments from non-ecological and high-carbon sectors to low-carbon sectors), support for new technologies, "green" financing, etc. can significantly increase financial support for the greening of the economy. A significant reserve for investments in the "green" economy can be the elimination of various types of subsidies and grants for nature-exploiting sectors. For example, the "brown" economy relies to a significant extent on traditional types of fuel. The total amount of subsidies for the production and consumption of fossil fuels in the world has exceeded 400 billion US dollars per year, which hinders the improvement of energy efficiency and the wider use of renewable energy sources (see Section V). There are many obstacles to the formation of a "green" economy, including those associated with widespread stereotypes. Thus, perhaps the most widespread is the myth of the existence of an inevitable contradiction between environmental sustainability and economic progress. There is now ample evidence that greening the economy does not hinder the creation of wealth or jobs, and that investment in many green sectors is a source of increased financial well-being and employment. However, the transition to a green economy requires the creation of new conditions, and this requires large-scale and urgent action by governments in all countries of the world. It is also often said that a green economy is a luxury that only rich countries can afford, or, even worse, that it is something that developed countries impose on developing countries so that the latter will remain poor forever. Modern research, including that of international organizations, provides many examples of the transition to a green economy in various sectors of the developing world that refute this idea - examples that deserve to be repeated in other parts of the world. Research also convincingly shows that greening the economy may not be a brake, but a new stimulator of development. The transition to a green economy is impossible without the economic benefits of such a course for public and private enterprises. It is difficult to make the economy "green" using only legal regulators and administrative measures, as shown by the global experience of the last decades. Among the main reasons for the negative impact of the economy on the environment, one can note the latency (secrecy) of a large number of environmental problems; the traditional market simply does not see them. The modern economy cannot accurately determine the benefits, damages and prices for the environment, "digitize" and economically present environmental problems for the government, business and society. To make greening profitable, at least three levers are needed: 1) stimulation of greening of the economy.

II. Methods

The European Investment Bank has identified three main reasons for the need to transition to a circular economy:

1. Resource constraints. Global demand for resources is increasing rapidly, leading to a growing deficit of critical raw materials and water.

2. Technological development. The introduction of new technologies enables the creation and implementation of circular economy business models. Without technological advancements and innovative approaches, it would be impossible to recycle, replace, and reuse resources, or to leverage new IT technologies.

3. Socioeconomic development. Circular models play a crucial role in the context of increasing urbanization. Urban areas are well-positioned to develop, implement, and maintain systems that can efficiently collect and return goods, materials, and other resources, leading to cost savings.

A fourth reason can be added—**environmental considerations**. Unused production and consumption waste occupies significant land areas, while pollutants migrate into the air, groundwater, and surface water, causing harm to public health, agriculture, and natural resources. These negative externalities lead to substantial environmental damage, including socioeconomic impacts. The circular economy must internalize these externalities and aim to minimize all forms of harm.

Potential future resource constraints due to rising global demand are also highlighted in OECD forecasts. Over the past few decades, the demand for resources has surged due to rapid industrialization in emerging economies and the growing needs of developed countries. Since 1980, global consumption of various materials has more than doubled. This trend is expected to continue, driven by population growth—from 7 billion people today to approximately 10 billion by 2060—accompanied by rising incomes and demand. According to OECD projections, if current trends persist, global use of material resources will rise from 79 billion tonnes in 2011 to 167 billion tonnes by 2060. Demand for metals, in particular, is forecast to increase from 8 billion tonnes to 20 billion tonnes by 2060, or 2.5 times.

The goal of the circular economy is to establish closed ecological and economic cycles, making the most efficient use of incoming raw materials in production processes, minimizing waste generation, and integrating accumulated waste back into economic activity. This approach aims to replicate natural cycles through environmentally compatible technologies across industries and responsible consumption models, forming analogs of ecosystems. The biosphere is a closed system where all elements are interconnected, and no waste is generated. In contrast, the modern technogenic economy operates as a linear, open system, where the production of a relatively small final product requires vast resource consumption and generates large amounts of waste. Currently, only 2-6% of the total volume of extracted natural matter becomes a final product, with the remainder becoming waste (e.g., tailings, slag, wastewater, etc.).

Humanity is familiar with relatively closed economic systems, such as traditional agriculture. In this system, waste is minimized: agriculture supplies livestock with feed, including byproducts from crops like grains, sunflower, and sugar beet, while livestock, in turn, provides agriculture with organic fertilizers that enhance soil fertility. This creates a more or less closed cycle of materials, resembling natural ecosystems.

III. Results

One approach to assessing the effectiveness of a circular economy can be the product recycling rate. It can be determined using the following formula:

$$r = Rr / Ra,$$

where r is the product recycling rate, Rr is the volume of recycled waste, Ra is the total volume of waste.

Traditionally, materials such as glass, paper, cardboard, and aluminum (e.g. packaging and containers) are recycled around the world. In some countries, the recycling rate of these materials exceeds 0.9. However, in Russia, this figure is significantly lower.

Assessing the effectiveness of the transition to a circular economy and the costs associated with it is an important issue. The benefits of transitioning to such a model include the recycling of resources, energy production from waste, and other forms of reducing environmental impact. Although the introduction of low-waste technologies may be costly, taking external costs into account can significantly increase overall efficiency.

Waste and pollution have a significant negative impact on human health and lead to environmental degradation. Therefore, choosing "cheap" solutions that require minimal initial investment can result in large social losses. For example, an important problem is the disposal of solid municipal waste. If it is solved using simplified incineration technologies, this can lead to significant harm to public health due to emissions of dioxins, particulate matter and other harmful substances. Positive and negative externalities (external effects) of the development of a circular economy are presented in Table 1. There may be a certain symmetry between positive and negative externalities. For example, a reduction in the extraction and use of renewable and non-renewable natural resources, which reduces the burden on the environment, can simultaneously lead to a decrease in income and employment in sectors engaged in the exploitation of natural resources.

Table 1: *Externalities of the development of the circular economy*

Positive Externalities	Negative Externalities
Reduction in the extraction and use of renewable and non-renewable natural resources	Additional consumption of resources and energy during recycling of products and waste
Reduction of negative environmental and health impacts from waste, including decreased landfill areas	Decrease in revenues for natural resource exploitation sectors
Development of resource-saving technologies	Reduction in employment in natural resource sectors
Creation of additional jobs	Potential negative health impacts from improper waste disposal (e.g., low-tech waste incineration)

IV. Discussion

Limited resources and investments in the economy necessitate prioritizing certain areas in the transition toward sustainable development and the formulation of environmental and economic policy. A common demand today is for a substantial increase in environmental protection expenditures. Typically, these costs are compared to total investments in the economy, gross domestic product, or benchmarked against those of developed countries. However, environmental protection costs are often narrowly defined, referring only to direct measures such as treatment facilities, filters, reclamation projects, and similar initiatives. This approach is incomplete and flawed.

Investments should be directed where they will yield the greatest environmental and economic returns and prove most effective. So, what should be considered environmental protection costs in this context? In a resource-intensive, raw material-based economy, priority should be given to structural and technological transformation, focusing on the development of low-emission technologies. This approach would help withdraw large volumes of inefficiently used natural resources from active circulation and alleviate the environmental burden.

To frame it differently, current investments should be divided between addressing immediate issues (i.e., direct environmental protection measures) and ensuring long-term sustainability (mainly through structural and technological shifts, such as adopting best available technologies—BAT). By investing in the resource-saving structural and technological transformation of the economy, making it more sustainable, and reducing its natural resource intensity, we can simultaneously minimize the costs of addressing the negative environmental impacts of industrial economic development.

It is challenging to justify the need for simply increasing environmental protection costs, as financial resources are always limited in the economy. Instead, it is crucial to demonstrate the high economic efficiency of environmentally-oriented measures, even if these benefits are not immediately obvious. This is achievable when accounting for the true economic value of nature and ecosystem services (as discussed in Section III). In a transforming economy, unlike in developed economies, there is a significant opportunity to capture substantial environmental benefits ("ecological cream") through purely economic structural projects and programs.

The primary focus should now be on economic policies that offer a "double win"—policies that generate both economic gains and significant environmental benefits. These include modernization, the spread of innovation, energy conservation, and the development of high-tech, infrastructure, and manufacturing industries. In other words, economic measures should simultaneously produce associated positive effects in the ecological sphere.

The global green economy, encompassing markets focused on climate and environmental solutions, has seen substantial growth over the last decade, presenting a compelling investment opportunity. In 2023, it rebounded strongly after a decline in 2022, with its market capitalization reaching $7.2 trillion by Q1 2024. Despite its recovery, challenges remain, including issues of overcapacity and trade barriers in renewable energy and electric vehicle (EV) manufacturing. Downsizing at several major U.S. green companies in early 2024 caused the green economy's share of the overall market to drop slightly from 8.9% at the end of 2023 to 8.6% in early 2024.

Despite these hurdles, the green economy continues to grow, with a long-term compound annual growth rate (CAGR) of 13.8%, outpacing the broader stock market. If treated as an independent sector, the green economy would have ranked as the second-best-performing industry over the last decade, only surpassed by the technology sector. For example, in 2023, the FTSE Environmental Opportunities All Share (EOAS) Index, a key measure of green economy performance, rose by 32%, compared to the 22% rise in the broader FTSE Global All Cap Index.

Since its inception in 2008 through March 2024, the EOAS has outperformed the benchmark index by 82%.

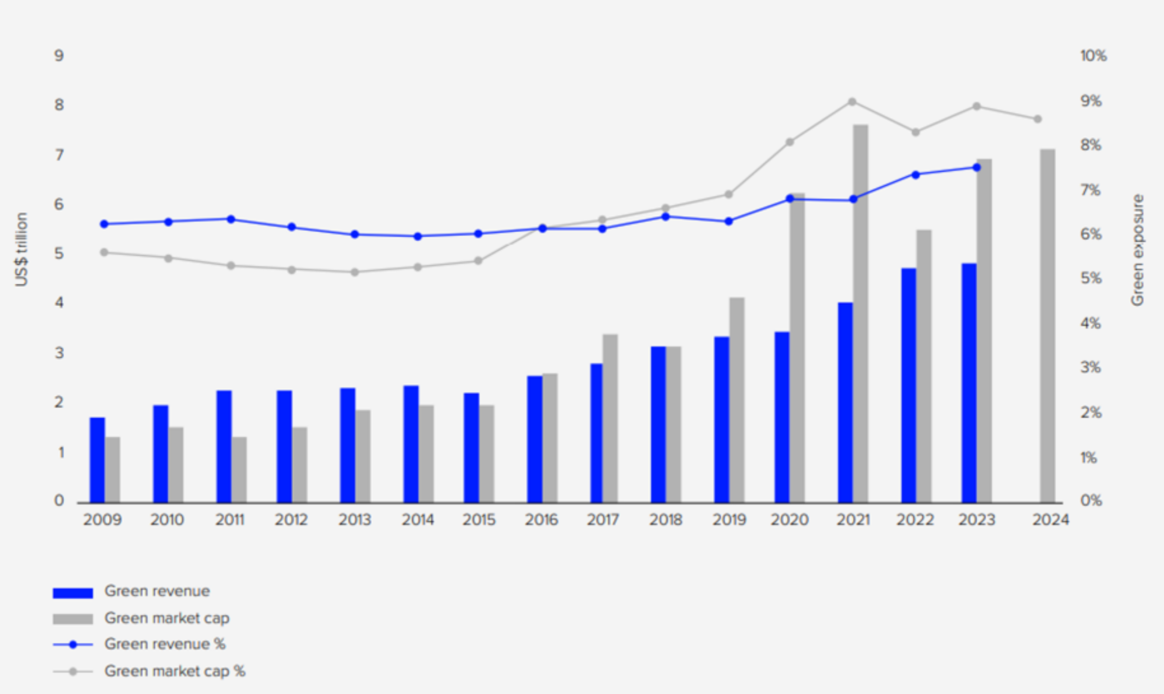

Figure 1: *Green economy 2009–2024*

However, not all green sectors have performed equally. The energy efficiency sector, which includes technologies such as efficient IT equipment and green buildings, has been the most successful, making up 46% of the green economy and generating 30% of green bond proceeds. In contrast, the renewable energy sector has lagged and underperformed in 2023, highlighting the uneven distribution of growth within the green economy.

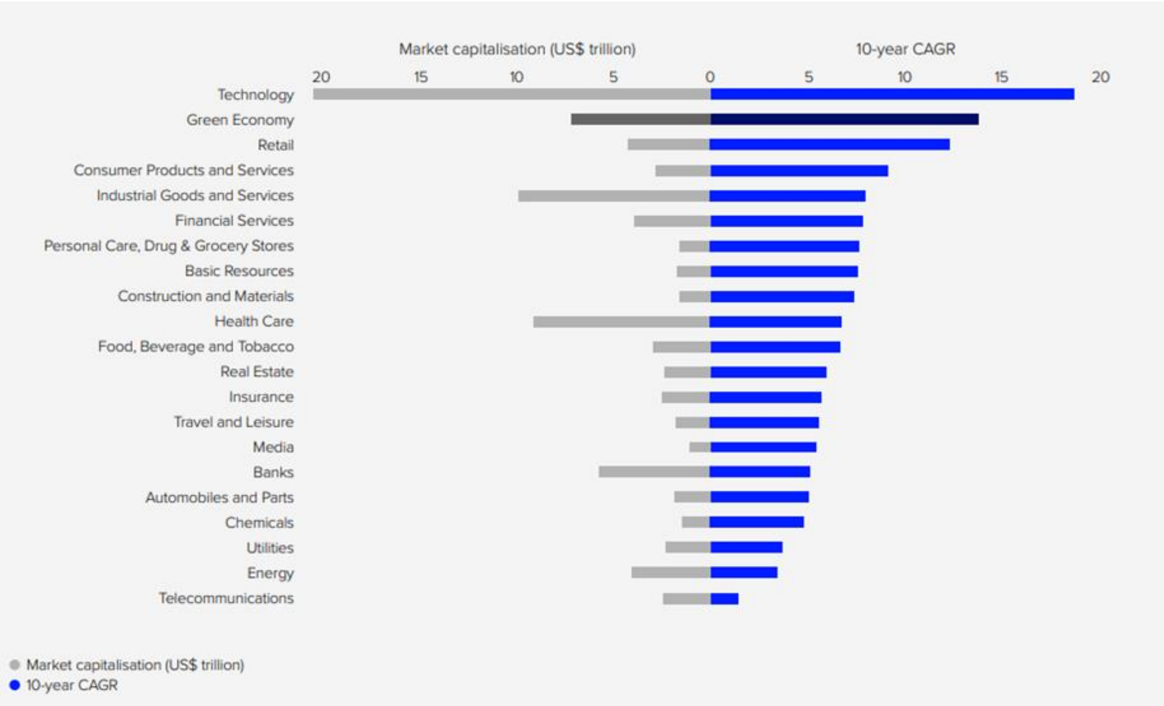

Figure 2: *Market capitalisation value and 10-year growth rate – Green Economy compared with ICB sectors*

If viewed as a standalone sector, the listed portion of the green economy in 2023 would have generated annual revenues nearing $5 trillion, with a market capitalization exceeding $7 trillion. This positioning would make it the fourth largest sector globally, surpassing industries such as Banks, Retail, and Energy, but still trailing behind Health Care, Industrials, and Technology.

Over the past decade, in terms of growth and financial performance, the green economy has only been outpaced by the Technology sector. If represented by the FTSE Russell Environmental Opportunities All Share Index (EOAS) and categorized as a separate ICB Industry, it would have ranked as the second-best-performing industry over the past ten years. Since 2008, the EOAS has consistently outperformed the broader FTSE Global All Cap Index by 82%, with significant outperformance occurring in 2020 and 2021.

The market capitalization of the green economy has expanded at a compound annual growth rate (CAGR) of 13.8% over the last ten years, compared to 8.3% for global equity markets. Revenues from the green economy have grown at a CAGR of 7.6% over the same period, exceeding the growth rate of combined revenues from all other companies (5.3% CAGR).

Within the green economy, the Energy Management and Efficiency sector has been the largest and highest-performing segment. Growing at 17% CAGR over the past five years, it now represents 46% of the green economy's listed equities and accounts for 30% of the proceeds from green bonds. This sector has driven the overall outperformance of the EOAS, leading ahead of other green sectors like Water and Renewable Energy.

A successful transition to a low-carbon economy requires a profound economic transformation, involving substantial mobilization of private finance. Achieving net-zero carbon emissions by 2050 is projected to necessitate additional global investments ranging from 0.6% to 1% of annual global GDP over the next two decades, equating to a cumulative total of $12 trillion to $20 trillion (IEA 2021; IMF 2021a). These investments must shift away from the fossil fuel sector towards renewable energy and low-emission technologies across various sectors. Therefore, a significant and urgent green investment push is essential to facilitate this transition (as outlined in the October 2020 World Economic Outlook).

The global financial sector is positioned to play a critical role in catalyzing private investment to accelerate the transition. In recent years, sustainability concerns—including environmental, social, and governance (ESG) factors—have increasingly become integrated into investment strategies, driving the growth of sustainable finance (October 2019 Global Financial Stability Report). Investors focusing on sustainability may have dual objectives: financial returns ("doing well" by accounting for sustainability's growing importance for profitability) and advancing sustainable economic development ("doing good," particularly by supporting a faster transition to a low-carbon economy).

Achieving net zero will likely require an annual investment of US$1 to $2 trillion in real terms, or about 1% to 2% of global GDP (see Figure 3). This level of spending would far exceed previous major economic stimulus initiatives, such as the Marshall Plan (equivalent to US$114 billion today). Moreover, the decarbonization effort will be a long-term endeavor, requiring sustained capital expenditure for at least the next two decades. With capital investment representing 7% to 14% of total global investment annually, the intensity of capex as a share of global GDP will reach around 28%—a level not seen since the global financial crisis or the 1970s. This combination of massive spending, supportive policies, and evolving consumer and investor preferences is expected to trigger a new capital cycle.

Government commitments to decarbonization, such as the recently passed US$1.2 trillion U.S. infrastructure plan and the European Green Deal, are playing a critical role in legitimizing and accelerating the green capital expenditure (capex) cycle:

- Governments are framing investment in the low-carbon transition as a key tool for economic recovery. Renewable energy projects, like solar, wind, and hydro, are more labor- and capex-intensive than traditional power generation, making them effective at creating jobs and stimulating economic activity.

- Consumers, increasingly aware of the physical and financial risks of unchecked climate change, are pressuring policymakers and investors to take meaningful action.
- Rising geopolitical tensions are pushing governments to prioritize energy security, climate-tech leadership, and resilient supply chains. The development of regional supply chains for electric vehicles (EVs), batteries, and critical raw materials will further drive capital investment by duplicating supply chains.

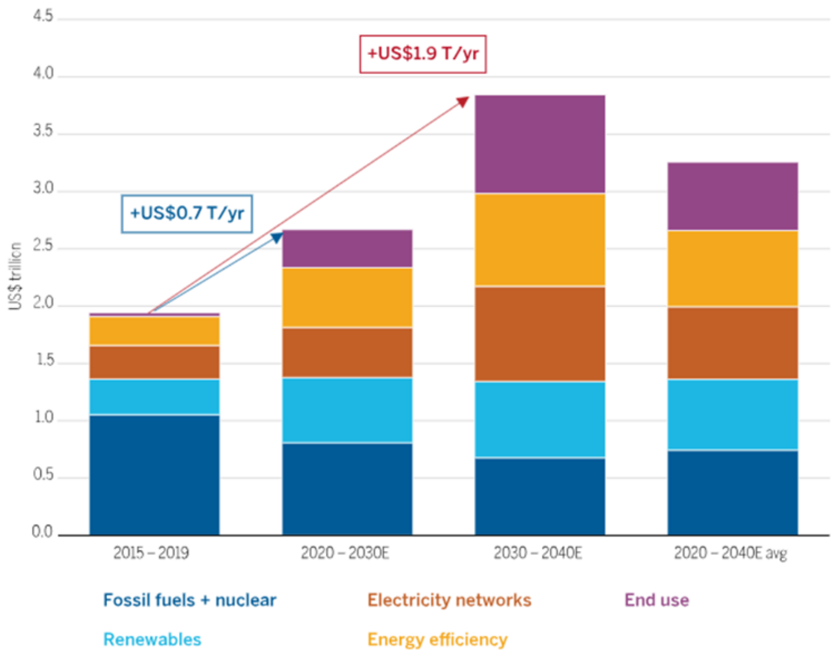

Figure 3: *Spending needed to achieve net-zero emissions by 2040*

Within the broader landscape of sustainable finance, the investment fund sector is particularly noteworthy due to its growing size and emphasis on sustainability-related issues. The sector has expanded substantially since the global financial crisis and now comprises around one-third of the assets held by nonbank financial institutions. It is at the forefront of incorporating sustainability considerations, including climate change mitigation, into investment decisions. This trend is evident from the increasing number of investor and asset manager networks committing to decarbonization efforts and integrating sustainability into their strategies.

Recent survey data and research indicate that investment funds, particularly those with a sustainable investment mandate, are increasingly attentive to climate change and the green transition. Financial markets have begun to reflect the pricing of the transition, which is crucial to steer capital toward firms and projects that positively impact climate change mitigation while avoiding overinvestment in non-sustainable ventures.

However, while the investment fund sector plays a pivotal role in advancing the green transition, financial stability risks associated with this transition are also significant. The path to a green economy remains uncertain, with variations across countries based on differing policies, adoption of clean technologies, and shifts in consumer and producer preferences towards low-emission products and services (October 2019 Fiscal Monitor; October 2020 World Economic Outlook). Transition paths could offer opportunities for high-return investments but also present risks, particularly for firms in sectors vulnerable to cleaner technologies (e.g., fossil fuels, energy-intensive industries).

Studies have documented the substantial exposure of investment funds to sectors most sensitive to the transition, such as fossil fuels, utilities, and energy-intensive manufacturing. A sudden transition shock, such as the rapid realization of the need for swift global change, could lead to a sharp repricing of these assets, potentially triggering financial stability risks.

This paper explores the interaction between the global investment fund sector and the transition to a low-greenhouse-gas economy, addressing two key questions: How do sustainable investment funds, which pursue both financial and sustainability objectives, support the transition? And what has been the impact of transition shocks on the investment fund sector so far? To answer these questions, the chapter develops a conceptual framework that examines the interlinkages between the investment fund sector and the green transition. Using a dataset of more than 54,000 open-end funds—including equity, fixed-income, and allocation funds—it conducts empirical analysis to assess the role of these funds in facilitating the transition and how they have responded to transition-related risks.

Abstract

Poverty as a multidimensional phenomenon is the result of an influence from many factors that lie in all social reproduction systems, on one hand. And otherwise it can be produced by the socio-psychological nature of people himself. This is not due to the fact that studying the factors of poverty that determine its development is not given much attention. At the best, most specialists are focused on assessing the quantitative assessment of poverty, and studying the economic behavior of households. Poverty has been inherent in any society, but the scale of manifestations and consequences differ at different stages of development. At the moment, it is obvious that the definition of measures and instruments of influence to reduce poverty should begin with an analysis and disclosure of the causes of its occurrence, and in our country-the reasons for its great increase. It is clear that there are many factors at work on reducing poverty as well as construction of comprehensive strategies to overcome this problem.

Keywords: problem of poverty, social stratification, socio-economic factors

I. Introduction

Today, a significant number of people on Earth live near the poverty line, which is manifested in an increase in social differentiation between the incomes of the poor and rich segments of the population (Table 1). An increase in poverty in the future may lead to destabilization of world economic development. Poverty remains a significant problem for the Russian Federation as well. Despite the wealth of natural resources, high intellectual and technical potential, and the active creation of new jobs, up to 1/5 of the population in Russia still lives in poverty, which hinders the further development of society [8, p. 9]. Thus, the direction of statistical accounting of the scale of poverty, control of its dynamics, as well as theoretical understanding of the causes and forms of poverty in order to develop adequate measures to overcome it is recognized as relevant today. In the scientific literature, poverty is understood as such conditions of a person's existence, which, firstly, are caused by a lack of finance and other material resources, and, secondly, do not allow them to lead a normal, full life [5, p. 265]. In other words, poverty is the inability to independently satisfy basic needs - food, housing, clothing, etc. With the transformation of society, the set of basic needs expanded (for example, education and health care were added to them), and the methodology for recording poverty changed accordingly. It is traditionally accepted to divide poverty into two types:

1. Absolute (extreme) - the need for resources that ensure the biological survival of a person becomes the main problem

2. Relative poverty - a comparative characteristic of living conditions in relation to the generally accepted standard of living standards. Relatively poor in the West can be considered people who have enough money to feed themselves, but not enough for education, cultural activities, etc. At the same time, in lagging countries such a person can be considered almost a

middle class [1, p. 13]. The other two forms of poverty are stable and floating. The first is a systemic phenomenon, when poverty becomes the norm for several generations. From poor parents, life attitudes and values, possible problems with health, education and employment are transmitted to children [2, p. 41]. Floating poverty is due to the fact that the poor, through an incredible strain of internal forces, overcome poverty, becoming full members of society. Of course, personal qualities alone are not enough - to make such a leap, it is necessary to create social conditions conducive to overcoming poverty [7, p. 6]. Speaking about the scale of the spread of poverty, it must be emphasized that in the context of globalization, when the world space becomes economically unified, the deterioration in the standard of living can occur everywhere, anywhere in the world [1, p. 22]. According to the World Bank report (for 2018), 736 million people live in absolute poverty (with a daily income of less than $1.9 per day). (about 12% of the world's population). 43% of people (3.4 billion) earn less than $5.5 a day. The poorest countries on Earth are the Democratic Republic of the Congo (the absolute poverty rate is 77.1%) and Madagascar (77.6%) [7, p. 4–7]. In the Russian Federation, according to Rosstat data for 2020, about 20 million people (up to 15% of the population) live below the subsistence minimum (less than 11,329 rubles per month) [6]. Since 2015, there has been an annual increase in the number of the poor by 1 million people [3, p. 10]. The official subsistence level is in fact the poverty line. The economic stratification of the Russian population is uneven. Thus, in the central part, the poverty level is significantly lower than the level of some East Siberian regions, where this indicator reaches 40% [6]. Some researchers believe that the real level of poverty is significantly lower than the declared one, since official statistics do not take into account the "shadow" incomes of citizens, unofficially employed, etc. [8, p. 31].

Table 1: *Poverty estimates for reference year 2019, changes between September 2022 and March 2023 vintage by region and poverty lines*

Region	Survey Coverage (%)	$2.15 (2017 PPP) Headcount ratio (%)		$2.15 (2017 PPP) Number of poor (mil)		$3.65 (2017 PPP) Headcount ratio (%)		$3.65 (2017 PPP) Number of poor (mil)		$6.85 (2017 PPP) Headcount ratio (%)		$6.85 (2017 PPP) Number of poor (mil)

The study of what factors and cause for the development of poverty has not yet been given due attention. A socially organized cross-sectional survey is rare. Socially organized cross-sectional surveys are very rare. In general, one has to rely on the research of the World Bank. Research that has not been done in this area hinders the effectiveness of effective policy. The absence of such research is unnecessary for the development of effective policies. Experts, at best focus on the quantitative assessment of poverty and the study of the economic behavior in families. Poverty is seen as a result of the crisis situation in the economic system or other, distributive relations. All researchers in poverty issues, the latter is caused by an imperfection of economic, social or political systems (called as "structural reasons for poorness". Some experts (O. Lewis, B.Stapelton, J. William and others) consider poverty in the broad cultural-historical aspect as part of the culture that is determining its effectiveness by determining stereotypes and standard behavioral attitudes in different circumstances: not directly involving economic activity but determining its effectiveness. If a country has had low economic and high-growth rate for several decades, then poverty becomes part of the economic culture. It manifests itself as a specific norm of behavior, an individual institution. Poverty is a special form of social activity that has its own uniqueness. The institutional environment in such a country is developed and develops in such a way that poverty is part of its components.

II. Methods

Monitoring of poverty is the basis for monitoring the quality and standard living in population, identifying its most vulnerable categories exposed to the risks of social support; development of effective measures that increase income from work and social support for people with low labor potential and high demographic burden on working women. In order to solve a poverty problem and organize proper monitoring, options such as determining the poverty line, determining standards in terms of quality life and standardizations in relation to this level, taking into account the poverty line play an important role (Fig.1). The choices and methods for establishing the poverty line, determining what is required to measure the poverty line, take into account it. An assessment of the living standard for Russians in terms of social policy, federal programs and economic program development; determining minimum wages at an official level. The budget is compiled by collecting data on consumer baskets, mandatory payment systems and wages that are compared to national monetary income. Accordingly, the poor include those whose incomes do not reach this poverty line, i.e., the subsistence minimum. Data on the number of the poor, on the characteristics of their quality and standard of living, their groupings according to various criteria, etc. are tracked and published by the Federal State Statistics Service. Data are presented for the population as a whole, for its individual categories, for households and their various groups.

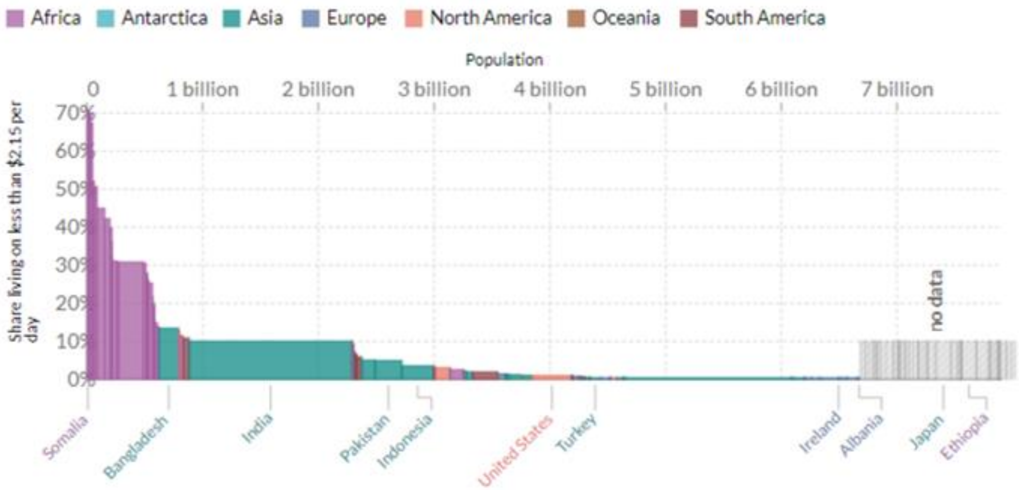

Figure 1: *Share of population living in extreme poverty, 2021*

The subculture of poverty as an economic category has shown that there are a number of issues about the possibilities for its possible presence. As a result, due to the heterogeneity of the poor group and the heterogeneity in this subcultural community, one cannot speak of a subculture that is poverty when its values are not accepted by all members from this subcultural community.

As a result of this, the group of the poor as a socio-economic group is (by definition) relativistic due to its fact that only people who fit the standard for material wellbeing stand out from the rest of the population. The "weak point" of the subculture theory of poverty is also that it often turns out to be unclaimed in practice due to its limitations, which expresses in the ineffectiveness of measures and systems to eliminate the latter. This is reflected in the ineffectiveness of measures and systems to eliminate the latter. It is possible to reduce these limitations of the poverty subculture theory, supported by many researchers, in terms of this [1]:

1. The purpose of this is not to eliminate poverty by increasing the income level of the poor. It is necessary to change the poor, themselves or children.

2. The fact that there is a phenomenon of subculture of poverty is disputed. 2. The existence of the very phenomenon of subculture of poverty is questioned. At the same time, it is arguable that the attitudes and value of the poor are so different from people within one community as to create "subcultures" of poverty. It is impossible to plan your future with materials, material resources and financial stability without material resources and money.

3. A possible intergenerational transmission of poverty is criticized. 3. The possibility for intergenerational transmission in a generation is criticized. For example, parents rarely raise children in exact the same way as before. Their behavior and value are not "passed on intact" to next generation, producing a cycle of deprivation. Because the idea of a "cycle of deprivation" is too deterministic and ignores the fact that social and economic conditions change, as well as people's condition.

4. It is not possible to accept that the poor are a stereotype of people who are passive and apathetic in public life. In fact, one person will not have time for savings or other resources on his own after poverty.

5. It is not the poor that are responsible for reducing social security, in particular and for creating subcultures of poverty in general. But rather it is state and government that support dependency. 6. The reason for this was no one else but the people who were to blame for them.

III. Results

Many models and approaches to eradicating poverty in the world have been developed over the years (Fig. 2). Some of these include improving education, access to healthcare, and job creation; boost economic growth through infrastructure development for rural areas. Other activities are aimed at strengthening the social protection of the population (including assistance programs), stimulating labor to create new enterprises, as well as expanding support programs. International organizations, governments and non-profit social initiatives also play a big role in helping to eliminate poverty through financial assistance to developing countries.

A number of scientists, in their scientific works, distinguishes a variety of levels that characterize the quality of life of the population [2]. These levels include: incomes of the population; the cost of living; consumption of the population; the main integral indicators of the life of the population; provision and coverage of the population with infrastructure facilities and technical means of the sectoral social sphere; demographic parameters. The standard of living of the population of Russia is determined by the following main indicators: the volume of gross domestic product per capita; the volume of production of essential goods; inflation rate; unemployment rate; the value of real income per capita, etc. The wealth of the population is the amount of money and material goods received or produced by households over a certain period of time. The level of consumption of the population directly depends on the level of income. It is important for the state to ensure that the level of income, as well as the standard of living of the entire population of the country, is approximately at the same level, and there is no poverty. This position is shared by a number of countries, including Norway, Finland, Denmark and other countries. In them, the level of stratification among the incomes of the population is insignificant [3]. However, there are also countries in which one can observe the stratification in terms of the level of income of the population, which ultimately leads to poverty of the population. In the European Union, poverty is defined as the lack of sufficient resources to maintain a generally accepted standard of living in society. For example, in Finland the poverty threshold is measured more accurately in relation to the level of the minimum budget, taking into account the criteria of absolute poverty, this approach allows to identify the part of the population whose income is below the level of the minimum budget. The results showed that there are significantly fewer people living in Finland below the minimum budget poverty line than those living below the relative poverty line.

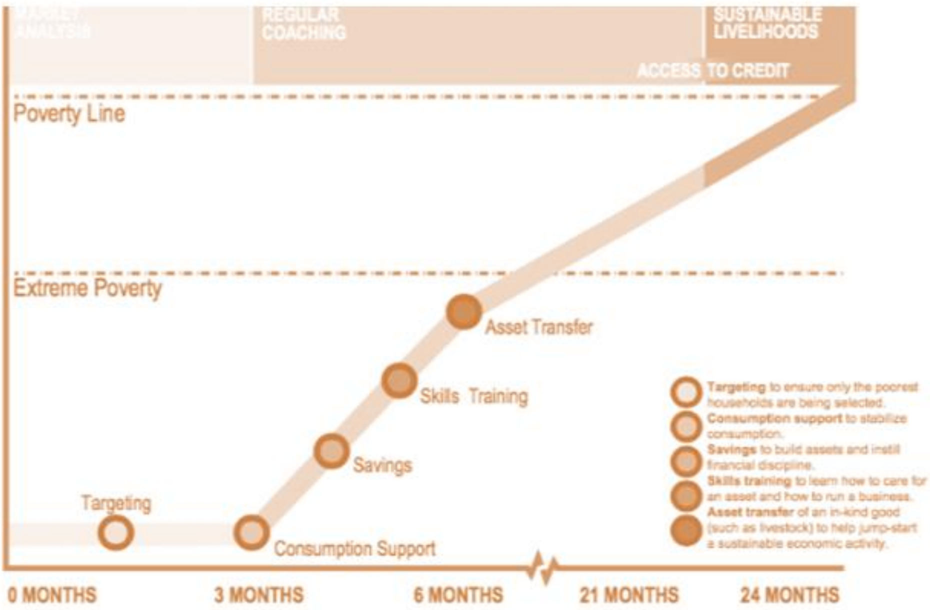

Figure 2: *The Graduation Model of ending extreme poverty*

According to the information provided, the subsistence level of persons living alone is 600-669 euros per month, regardless of age and housing costs. Housing costs are 156 euros, while renting an apartment costs an average of 388-540 euros. Students (24.9%), lone guardians (20%), unemployed (16.6%) and living alone (16.1%) were among the most vulnerable citizens with incomes below the minimum budget poverty threshold. Despite the enormous scientific and industrial growth that accompanied society in the 20th century, the social difference in today's society is only growing. Moreover, social division is becoming more complicated in absolutely all countries of the world, including developed countries. In the most common language, the poor are getting poorer, and the rich are getting richer [3]. Let's go back to the problem of poverty in Russia. Rosstat recorded an increase in poverty in the Russian Federation. The degree of poverty in the Russian Federation, after increasing the subsistence minimum more than the stagnation of the economy in the second quarter of 2019, amounted to 12.7% compared to 12.5% a year ago. According to the correlation, the coefficient decreased by 1.6% from the initial quarter [4]. The number of Russian residents with cash incomes below the subsistence level in the second quarter of 2019 amounted to 18.6 million people, or 12.7% of the total population. Thus, the poverty rate in Russia increased by 0.2% in annual terms. This is due to the fact that the cost of living in the second quarter of 2019 increased by 7.1% compared to the same period in 2018, and also amounted to 11,185 rubles, while the stagnation of the economy in annual turnover was 5.6%. In 2020, the authorities are thinking about abolishing the income tax for the poor and introducing a deduction for all workers. We can talk not only about the abolition of personal income tax for the poor (whose income is about 10 thousand rubles), but also the introduction of a deduction of 1.5 of the subsistence minimum for everyone. At the same time, the personal income tax rate may increase

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

from 13% to 16%. "If we talk about tax cuts for very low wages, it is very indirectly related to the poor, but of course, any tax cut is always welcomed by everyone. But in this case, if we are talking about the fight against poverty, today I would see more effective subsidizing tools based on per capita income in the family and, accordingly, the allocation of appropriate subsidies on this basis, "said Aleksey, Chairman of the Accounts Chamber, about this project.

IV. Discussion

The usual model of fighting poverty includes a large set of strategies and activities aimed at improving the quality of life of people AND eliminating economic inequality. Key approaches to fighting poverty include [5]:

1. Education is an important component of increasing the level of employment and income. The main factors to reduce poverty are investment in education and affordable quality of education.

2. Stimulating economic growth and creating jobs can help reduce unemployment and raise the income level of the population.

3. Increasing social protection: support is provided to the poor. There are also benefits, health insurance and social assistance.

4. Investments in infrastructure contribute not only to the development of the region, but also to improving the quality of life of the population. An example is the construction of roads, water supply.

5. Financial and technical support for entrepreneurs - small business contributes to the creation of new jobs, as well as the development of the economy.

6. Statement of gender equality: A defining precondition for poverty reduction is that women have more equal opportunities to participate in the economy and education.

7. Agricultural support: Building infrastructure in rural areas helps reduce migration and creates new business opportunities.

Anti-poverty tactics involve an integrated approach between both government, international organizations and civil society to achieve meaningful momentum.

Most often, women who find themselves with children without material support from their spouses can be primarily attributed to the poor. A unique phenomenon of the "working poor" has emerged in the Russian economy. Employed citizens who perform their labor functions in the workplace receive such low wages that they can be interpreted as "working poor" [1]. So, poverty is a socio-economic phenomenon in which an individual or social group cannot satisfy the minimum needs necessary for life. Any country can become poor or rich. There are a number of countries that have historically been within the poverty line. Here we are talking mainly about African countries, such as the Congo, Zimbabwe, Mali and others. In these countries, the poverty level of the population, according to statistical reports, is in the range of 55–65%. Poverty has two aspects: economic (associated with the level of the individual's well-being, expressed in the presence of a minimum amount of liquid values) and social (a special way of life, its style and norms of people's behavior). Note that poverty looks different in different countries of the world: 1) China is one of the most developed countries in the world. Poverty accounts for 65% of the country's population; 2) The US is about 16% poor of the total population. In America, there is the concept of "a poor working person." Poverty is always associated with unemployment. A person who has found a job cannot be poor by definition; 3) Japan is the third power in the world in terms of economic power, but every year the level of poverty in the country is growing. The main reason is unemployment. Every sixth Japanese is considered poor. Today, one of the leaders in terms of the level and quality of life are such countries as Norway, Australia, Sweden [4]. In many countries of the world, the main directions for reducing income inequality and poverty levels are (Fig. 3):

• development of programs to promote employment of the population;

• improvement of social and housing conditions;
• Stabilization and improvement of the minimum wage and social benefits, etc.

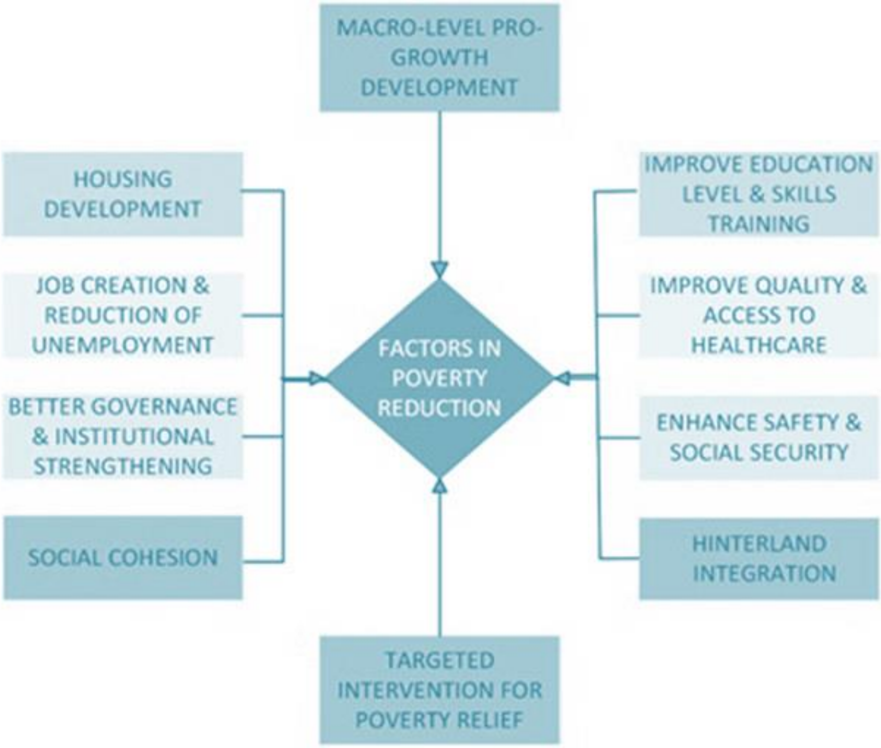

Figure 3: *Poverty Reduction*

The consequence of poverty, in the first place, is the disunity of the population into separate economic groups. There is a loss of common values and interests, a significant part of people are deprived of the opportunity to participate in the political and public life of the country. At the same time, we note that the attitude towards poverty has changed over the past hundred years. So, L.A. Zubkevich in his work "The influence of poverty as a social phenomenon on the worldview of people in modern conditions of social development (social-philosophical analysis)" notes that if at the beginning of the 20th century dissatisfaction with the position of the peasantry and the working class led to the October Revolution of 1917, today, in general, , society is more tolerant of differentiation in terms of welfare [4]. As the level of poverty grows, the level of social tension also grows: the catastrophic situation pushes people to commit crimes and anti-government actions. However, even if the poor do not commit offenses, society still gradually stagnates: the higher the risk of an increase in the level of absolute poverty, the higher the risk of involvement in this process of more affluent strata of society [5]. The specificity of poverty that has developed in the Russian Federation is a consequence of the low level of wages (primarily in the public sector) and social benefits. So, if in Europe up to 60% of social assistance is distributed, then in Russia this figure does not exceed 20% [7]. Thus, the specificity of Russian poverty is characterized by the term "market poverty" - that is, associated with the position of the able-bodied population in the labor market. Market poverty is associated with low wages, lack of career prospects, inability to maintain full employment, which leads to an increase in unemployment and the shadow sector of the economy. In this context, the concept of poverty can also be defined as the inability to work. The decrease in the income of the population and the increase in social differentiation lead to an increase in labor migration. According to estimates, up to 11 million citizens of the Russian Federation lived and worked abroad in 2019. This is 7-8% of the total population, many of them are in demand and highly qualified specialists. The outflow of labor reserves leads to the decline of science and education, and the general decline in living standards leads to a demographic crisis and economic regression. The problem of reducing the level of poverty is complex and requires the efforts of all public spheres. In world practice, in general, there are two main approaches to overcoming poverty:

1. In developed countries, measures are taken to support the level of the minimum income of the population, which ensures the satisfaction of basic needs.

2. In developing countries, social policy is primarily focused on helping the most economically vulnerable categories of citizens, in comparison with the rest [7]. State support for the poor segments of the population reduces the level of poverty, but does not completely solve the problem. Moreover, the amount of social benefits in developed countries is so high that it leads to an increase in the unemployed: the able-bodied population refuses to work, relying on government assistance. Thus, social policy in the field of poverty reduction should be aimed at stimulating the economic activity of the population, and not at turning them into dependents. More important is the increase in wages and pensions, as the demand for paid medical and educational services, as well as for consumer goods, increases, so does their price. It is necessary to involve the population in labor activity, to support active and talented youth from economically underdeveloped regions, to promote the employment of people with disabilities. The private sector should also play its role in this policy by organizing charity events, helping orphanages, and so on. Thus, the problem of poverty today is global. Not only the state is interested in its resolution, but also the economically active population. The threat of impoverishment today hangs over well-to-do categories of citizens. Poverty affects not only representatives of the "lumpen-proletariat", but also scientists, low-skilled workers, and teachers. Poverty is not only an economically determined phenomenon, it is, according to L.A. Zubkevich, "lifestyle, psychological type of personality". Effective statistical monitoring of the level of poverty, stimulation of social policy, organization of preventive educational activities on how to get out of a difficult life situation - these are promising areas that contribute to overcoming poverty and social differentiation.

Abstract

The renewable energy economy has emerged as a critical component for achieving sustainable economic growth and combating climate change. With the increasing urgency to reduce greenhouse gas emissions, renewable energy sources such as solar, wind, hydro, and biomass are gaining prominence as viable alternatives to fossil fuels. This transition presents substantial potential for enhancing energy security, creating jobs, and fostering innovation in various sectors. However, the shift towards renewable energy also encounters significant challenges. High initial capital investments, the need for advanced infrastructure, fluctuations in energy prices, and the necessity for supportive government policies are all obstacles that need to be addressed. Additionally, the intermittency of renewable energy sources raises concerns about grid reliability and energy storage solutions. This paper explores the potential of renewable energy as a driving force for economic development, examining the various challenges that impede its widespread adoption. It discusses the importance of integrating renewable energy into existing energy systems and highlights best practices and successful case studies from around the world. Furthermore, the paper offers actionable recommendations for policymakers, businesses, and stakeholders to create a conducive environment for the growth of the renewable energy sector. By addressing these challenges and harnessing the potential of renewable energy, societies can pave the way for a sustainable and resilient economic future while contributing to global efforts to mitigate climate change.

Keywords: renewable energy, sustainable economic growth, climate change, energy security, job creation, innovation, fossil fuels

I. Introduction

The transition to a renewable energy economy has emerged as a critical pathway for addressing pressing global challenges such as climate change, energy security, and sustainable economic growth. As nations grapple with the adverse impacts of fossil fuel dependency, the shift toward renewable energy sources like solar, wind, hydro, and geothermal presents not only environmental benefits but also significant economic opportunities.

Renewable energy technologies have matured, and their costs have declined dramatically over the past decade, making them increasingly competitive with traditional energy sources. This shift is catalyzing innovation, driving job creation, and fostering new business models. However, transitioning to a renewable energy economy is not without challenges.

Barriers such as the need for substantial capital investment, the development of robust infrastructure, fluctuating energy prices, and the imperative of grid reliability must be addressed to ensure a smooth transition. Additionally, the integration of renewable energy into existing energy systems requires careful planning and strategic government policies that promote investment and innovation.

This introduction sets the stage for a comprehensive exploration of the potential and challenges associated with the renewable energy economy. By examining key factors such as technological advancements, economic implications, and policy frameworks, this paper aims to provide a nuanced understanding of how renewable energy can pave the way for a sustainable and resilient future.

Ultimately, the journey towards a renewable energy economy is not only essential for mitigating climate change but also presents an opportunity for nations to rethink their energy strategies and foster economic resilience in the face of an uncertain future.

II. Methods

This study utilizes the following three methods to analyze the potential and challenges of transitioning to a renewable energy economy:

1. **Literature Review**: A systematic review of existing literature will be conducted to gather insights on renewable energy technologies, economic implications, and policy frameworks. This will involve examining peer-reviewed articles, government reports, and relevant industry publications to build a robust theoretical foundation for the research.
2. **Case Studies**: In-depth case studies will be performed on selected countries and regions that have successfully implemented renewable energy initiatives. By analyzing their policies, technological advancements, and economic impacts, this method will highlight best practices and lessons learned that can inform future transitions to renewable energy.
3. **Surveys and Interviews**: Qualitative data will be collected through surveys and interviews with key stakeholders in the renewable energy sector, including policymakers, industry leaders, and academic experts. This method will provide valuable perspectives on the challenges and opportunities associated with renewable energy transitions, helping to capture a comprehensive view of the current landscape.

These methods collectively aim to provide a well-rounded analysis of the renewable energy economy, addressing both its potential benefits and the obstacles that must be overcome for successful implementation.

III. Results

Renewable energy sources (RES) are defined as clean energy sources that are naturally obtained and continuously replenished. These sources include solar, wind, hydro, tidal, geothermal, and biomass energy. In contrast, non-renewable energy sources, such as natural gas, coal, metal ores, and oil, cannot be replenished. Currently, more than 75% of global energy consumption is derived from non-renewable sources, which has significantly harmed the ecosystem, particularly the ozone layer. Notably, China and the United States are among the largest consumers of these energy forms.

Understanding global energy consumption and utilization is critical. Three major institutions—the International Energy Agency (IEA), the U.S. Energy Information Administration (EIA), and the European Environment Agency (EEA)—regularly record and publish energy data worldwide. Recent studies indicate that the use of renewable energy has substantially reduced carbon emissions. According to a 2019 report from the IEA, renewable energy capacity is expected to grow by about 50% between 2019 and 2024, with hydro, solar, and wind energy experiencing the fastest growth rates. As of the latest data, 26% of global energy consumption is based on renewable sources, with projections suggesting this could reach 30% by 2024. Furthermore, about one-fourth of the world's electricity was generated from renewable sources in 2017, with an expected increase of 1.3% that same year.

Despite the abundance of renewable energy resources in most developing nations, there remain significant challenges in harnessing these resources to their full potential. This limitation has adversely affected the overall growth rate of industrialization and development in these regions. More than 70% of the world's population resides in developing countries, primarily in Latin America, Africa, and Asia. Unfortunately, socio-economic activities in these areas, especially in Sub-Saharan Africa, are not very impressive. It is perplexing that, with such vast untapped renewable energy potential, governments and other stakeholders seem either uninterested in developing renewable energy technologies or resistant to the entire process. If there were a genuine commitment to investing in and advancing renewable energy initiatives, we would likely see a much higher flow of investments and improved development levels.

Countries worldwide are seeking strategies to move away from fossil fuels. This shift, driven by carbon emissions that worsen climate change, encompasses a wide range of renewable energy sources, including solar, wind, and hydro. However, is the transition to renewables as straightforward as merely selecting alternative energy sources? What other elements need to be addressed during this shift? Nutifafa Yao Doumon, an assistant professor in the College of Earth and Mineral Sciences at IEE, along with his students, have been contemplating the requirements for this transition, the potential challenges it may face, and the factors that could influence its success or failure.

We collectively recognized that achieving a successful energy transition is a complex challenge that necessitates a multifaceted approach. Although the following considerations may not encompass all aspects, they are essential for advancing renewable energy:

- Investment in renewable energy infrastructure
- Innovation in technology and research and development (R&D)
- Implementation of energy efficiency measures
- Supportive policy and regulatory frameworks
- Global collaboration and collective action

The transition to renewable energy is far from simple, facing numerous intricate challenges that encompass technological, environmental, societal, economic, and geopolitical dimensions. Here, I will briefly address the technological and geopolitical aspects to illustrate the complexity involved.

From a geopolitical standpoint, it is important to recognize the perspectives of many countries in the Global South. These regions often feel pressured by Western nations to adopt renewable technologies, arguing that they have not been significant contributors to greenhouse gas emissions. They contend that transitioning to alternative energy sources is not a priority, particularly when they have yet to achieve the developmental milestones experienced by the West. Many believe, especially in Africa, that this pressure could hinder the continent's efforts to escape poverty. These sentiments have been articulated in op-eds written by former Nigerian Vice President Prof. Yemi Osinbajo in *The Economist* and Ugandan President Yoweri K. Museveni in the *Wall Street Journal*, each emphasizing the need for a nuanced debate on the issue.

From a technological perspective, the notion of energy transition is often viewed as a complete shift from fossil fuels to renewable energy through innovative technologies. While this scenario is ideal for improving the planet's health, the reality may involve a significant reduction in fossil fuel use alongside a marked increase in renewable energy sources. Many renewable technologies are not yet fully developed and often cannot compete with fossil fuels in terms of societal integration. For instance, silicon-based solar technology, which is currently the most established, has an efficiency rating of 26% and a lifespan of 20 to 25 years. Other solar technologies, including organic, dye-sensitized, and perovskite solar cells, are still in the research phase and are not market-ready due to issues like low efficiency and instability.

One of the greatest challenges facing solar technology is that it cannot operate in isolation; it requires complementary storage solutions, such as batteries, to ensure availability around the clock. Additionally, solar installations demand substantial land, often impacting agricultural communities. The extraction of materials necessary for solar and battery technologies introduces a new array of challenges. Moreover, there are numerous concerns related to the lifecycle of solar panels, including their disposal and recycling.

IV. Discussion

There are numerous opportunities and lessons learned from past experiences that can facilitate a more equitable and sustainable transition to renewable energy. The deployment of renewable technologies often varies depending on regional, locational, or geographical factors. For instance, solar energy proves to be highly effective in hot climates, which are primarily located in the Global South, while wind energy thrives in areas with strong natural wind patterns.

Global collaboration and collective action are essential for investing in renewable energy infrastructure and fostering technological innovation and research and development (R&D) aimed at ensuring a just and sustainable transition. Historical experiences have demonstrated that the mining and processing of raw materials and minerals can have detrimental effects on marginalized, rural, local, or Indigenous communities. This understanding provides us with an opportunity to improve our practices this time around. Achieving this, however, necessitates active involvement from the communities themselves, alongside appropriate policies, supportive governments, and genuine political will.

These opportunities present a chance for researchers to diversify their work and collaborate across disciplines. It is vital to invest time and resources into the innovation and R&D of new technologies for renewable energy harvesting, conversion, and storage. Furthermore, it is important to ensure that communities understand and appreciate the technologies that could potentially supplement or replace existing fossil fuel-based systems and products.

Consequently, this shift will significantly impact how researchers approach their work, fostering a more interdisciplinary and community-focused methodology. Renewable technology companies and industries will also need to rethink their R&D strategies. Research should encompass evaluations before and after the development and deployment of new technologies. Researchers are increasingly aware of the carbon footprint of their work, prompting them to adopt new, efficient methods and integrate sustainability into their processes.

If we fail to acknowledge these challenges, we risk creating tension between the Global North and Global South, leading to potential geopolitical fractures. Global warming and climate change are threats that affect everyone and must be addressed collaboratively. Working together as equals, with a clear understanding of our respective strengths and weaknesses, is essential. Otherwise, countries in the Global South may resist the transition to green energy, potentially becoming immediate or future polluters, which runs counter to our desired goals.

From a technological perspective, there is a risk—however small—that we may not fully realize the potential of renewable energy technologies in time to effectively combat global warming. Additionally, in pursuing these technologies, we could inadvertently worsen environmental pollution, health risks, and the overall quality of life for various communities around the globe.

If we proactively address these challenges, the potential for positive outcomes is vast. We can tackle energy crises in key regions through global cooperation and collective action while protecting our environment through equitable treatment, climate justice, and efforts to mitigate global warming. A well-coordinated, collective approach can help us achieve our renewable energy and climate objectives, paving the way for a more sustainable and equitable energy landscape for future generations.

The COVID-19 pandemic has significantly disrupted the global economy, prompting governments to focus on job creation as a critical recovery strategy. As renewable energy technologies are still in their early stages, they hold the potential to generate a substantial number of jobs across various sectors, including planning, execution, construction, and maintenance. This job creation can serve as both a short-term and long-term stimulus to address rising unemployment, which currently affects one in every eight individuals.

To facilitate this transition, governments should implement policies aimed at limiting global warming to a manageable level of 1.5°C. Such policies should promote the complete transition to renewable energy while phasing out fossil fuels and converting them to synthetic or hydrogen fuels for power generation. Additionally, these policies must ensure that carbon emissions remain within global standards, prioritize greenhouse gas reduction, and foster collaboration among companies. The establishment of more renewable energy agencies can also help facilitate these goals.

Moreover, increasing public awareness about the benefits of renewable energy sources is crucial for enhancing overall health, economic stability, and environmental quality. Educational initiatives should emphasize the detrimental effects of global warming on humans, wildlife, and plant life, highlighting the risks associated with air and water pollution caused by conventional energy sources. In contrast, renewable energy sources do not contribute to such contamination, making them a healthier alternative.

Changing deeply held beliefs, especially those tied to religion, can be an arduous task. However, it is essential to promote awareness of the importance of renewable energy. Continuous and focused education efforts should aim to shift perceptions and highlight the significance of embracing renewable energy sources, encouraging creative educators to adapt to this necessary change.

Additionally, the electrification of rural areas using renewable energy sources should be a top priority for governments, particularly since these areas often lack access to the power grid. Governments should formulate policies that support rural electrification and engage stakeholders such as banks, investors, and industry owners. Access to grants and credit facilities must be made easier, enabling individual households to afford affordable home-based renewable energy products.

Governments should also create policies that bundle renewable energy sources with conventional energy sources in a hybrid generation model. This model could stipulate that 30% of total power generation comes from renewable sources while 70% is sourced from conventional means. Such regulations would help reduce greenhouse gas emissions and air pollution while increasing the penetration of renewable energy. Moreover, the pricing structure should favor renewable energy, offering lower tariffs compared to conventional sources.

Furthermore, there should be a concerted effort by governments to integrate renewable energy courses into educational curricula, starting from primary levels to higher education. This initiative, which is already seen in developed countries, will significantly boost public awareness of renewable energy's benefits. Educating children about the health and environmental impacts of conventional energy sources can foster a more informed future generation.

In conclusion, renewable energy represents a crucial path forward; however, it faces several challenges. These include high initial costs of acquisition and installation, inadequate government policies supporting its full utilization, low public awareness of its advantages, a shortage of trained personnel for installation and equipment procurement, limited research capabilities, and the proliferation of substandard products. Moreover, fears among investors due to political unrest and resistance from some groups who view renewable energy as a threat to their beliefs further complicate the transition.

To address these challenges, there must be a deliberate shift from conventional energy sources that contribute to greenhouse gas emissions toward renewable alternatives. With ongoing advancements in renewable energy utilization and the gradual reduction of non-renewable energy dependence, the global community can aim to significantly lower carbon emissions and mitigate climate change impacts in the future.

Abstract

Reproductive medicine and reproductive technologies play a significant role in achieving sustainable development by improving public health, promoting gender equality, and reducing social inequalities. These fields align with several Sustainable Development Goals (SDGs), including good health and well-being (SDG 3), gender equality (SDG 5), and reducing inequalities (SDG 10). Modern reproductive technologies, such as in vitro fertilization (IVF), genetic screening, and family planning methods, contribute to addressing infertility, improving maternal health, and providing access to reproductive rights. However, disparities in access to these technologies, particularly in developing countries, highlight the need for policies that enhance availability and affordability. Ethical concerns, especially around genetic interventions and surrogacy, must also be carefully addressed. Innovations in reproductive medicine can further contribute to population stabilization, resource management, and environmental sustainability, supporting a balanced approach to human development in the face of global climate change. The integration of reproductive technologies into sustainable development policies ensures equitable access to healthcare while considering the broader impacts on society, the economy, and the environment.

Keywords: reproductive medicine, reproductive technologies, sustainable development, gender equality, infertility treatment

I. Introduction

Reproductive medicine and reproductive technologies have become critical components of modern healthcare, addressing key challenges related to fertility, maternal health, and family planning. In the context of sustainable development, these fields are essential for achieving global goals that promote health, well-being, and gender equality. As global populations grow and environmental pressures mount, sustainable development demands a balanced approach to population health and resource management. Reproductive medicine, through innovations like in vitro fertilization (IVF), genetic screening, and assisted reproductive technologies, provides solutions not only for individuals facing infertility but also for broader societal issues, such as managing population growth and ensuring reproductive rights.

The United Nations' Sustainable Development Goals (SDGs) emphasize the importance of good health and well-being (SDG 3), gender equality (SDG 5), and reducing inequalities (SDG 10). Reproductive health is at the intersection of these goals, highlighting the need for universal access to healthcare services that support family planning, pregnancy care, and infertility treatments. However, disparities in access to these services remain a pressing issue, particularly in developing regions where economic and healthcare inequalities persist. The high cost of advanced reproductive technologies often limits their availability to affluent individuals or nations, exacerbating existing inequities.

Moreover, the ethical and social dimensions of reproductive technologies, including debates around genetic intervention and surrogacy, raise complex questions about the implications of medical advances on human rights and societal norms. As such, integrating reproductive health into the global sustainability agenda requires a careful balance between medical innovation, ethical considerations, and equitable access to healthcare.

This introduction explores the crucial role of reproductive medicine and technologies in the pursuit of sustainable development, highlighting both their potential and the challenges associated with ensuring that advancements in these fields benefit all populations equitably.

II. Methods

This study employed a comprehensive approach to analyze the Reproductive medicine and reproductive technologies to achieving health-related Sustainable Development Goals (SDGs). The methods utilized included:

1. **Literature Review**: An extensive review of existing literature on primary health care and its role in public health was conducted. This involved analyzing peer-reviewed articles, reports from international organizations, and relevant policy documents.
2. **Data Collection**: Quantitative data was gathered from national health statistics and databases, focusing on indicators related to health outcomes, access to primary care services, and SDG progress. Qualitative data was also collected through interviews with healthcare professionals and stakeholders to gain insights into barriers and facilitators of primary health care implementation.
3. **Stakeholder Analysis**: Key stakeholders, including government agencies, non-governmental organizations, and community representatives, were identified and engaged. Their perspectives on the effectiveness of primary health care services and Reproductive medicine and reproductive technologies.
4. **Case Studies**: Specific case studies were conducted in various regions to illustrate best practices and challenges in primary health care delivery. These case studies provided context-specific insights and highlighted successful interventions that align with SDG objectives.
5. **Policy Recommendations**: Based on the findings, policy recommendations were developed to enhance the effectiveness of primary health care services. These recommendations aimed to address identified barriers and promote multisectoral collaboration to achieve health-related SDGs.

The analysis emphasized a holistic view of primary health care, integrating both health service delivery and broader determinants of health to provide a comprehensive understanding of its role in advancing public health goals.

III. Results

Reproductive medicine is a rapidly evolving field focused on the diagnosis and treatment of infertility, a condition defined as the inability of a man and a woman of childbearing age to conceive a child after two years of regular, unprotected sexual intercourse. Infertility can be influenced by a variety of factors, including age, health conditions, and lifestyle. In many cases, healthcare professionals suggest seeking medical advice sooner—typically after 12 months of unsuccessful attempts to conceive. For women over the age of 35, it is often recommended to consult a specialist after six months of trying to become pregnant, as age can significantly impact fertility.

This field encompasses a wide range of diagnostic procedures and treatments, from hormone therapy and medication to advanced reproductive technologies such as in vitro fertilization (IVF). Its rapid development is driven by both increasing demand and advances in medical research, making it a crucial area of modern healthcare.

Reproductive technologies encompass a variety of methods designed to enhance the likelihood of fertilization and assist individuals or couples facing infertility challenges. These technologies include:

- In vitro fertilization (IVF): A process where eggs are retrieved from a woman's ovaries and fertilized by sperm outside the body, in a laboratory. The resulting embryos are then transferred to the woman's uterus to establish a pregnancy.
- Intracytoplasmic sperm injection (ICSI): A procedure in which a single sperm is injected directly into an egg to facilitate fertilization, often used when there are male infertility issues.
- Intracytoplasmic morphologically selected sperm injection (IMSI): A more advanced form of ICSI, where sperm is examined under high magnification to select the best-quality sperm for injection, increasing the chances of successful fertilization.
- PICSI (physiological intracytoplasmic sperm injection): A selection method for ICSI, where sperm are chosen based on their ability to bind to hyaluronic acid, mimicking natural selection processes to ensure better sperm quality for fertilization.
- Egg donation: The use of eggs donated by another woman to help individuals or couples conceive when the female partner's eggs are unsuitable for fertilization.
- Sperm donation: The use of sperm from a donor to facilitate fertilization, often used in cases of male infertility or for single women or same-sex couples wishing to conceive.
- Surrogacy: An arrangement where a woman (the surrogate) carries and delivers a baby on behalf of another individual or couple, often used when pregnancy is medically impossible or risky for the intended mother.

These reproductive technologies offer a range of solutions to increase the chances of conception and are widely used in modern reproductive medicine.

IV. Discussion

Experts identify several major causes of both female and male infertility, many of which are linked to environmental and lifestyle factors. Key contributors include exposure to unfavorable environmental conditions, harmful working environments (particularly for men), and sexually transmitted infections (STIs). Additionally, delaying childbirth for career or financial reasons and leading unhealthy lifestyles—characterized by alcoholism, smoking, and drug use—also play a significant role in infertility. Worryingly, the rising number of teenagers and young adults who engage in harmful habits is expected to further increase the number of couples struggling to conceive in the near future.

A critical factor contributing to the decline in reproductive health is the relatively high number of abortions, which continue to be used as a method of birth control. Over 50% of abortions occur among women aged 20 to 30, with an additional 20% in women aged 30 to 34—those in their most active reproductive years. Alarmingly, adolescent abortions are also a growing concern, with 8-10% of total abortions being performed on girls under the age of 19. This rate is much higher than in many Western countries.

The persistently high rates of abortion are largely attributed to the insufficient use of modern contraceptives. Data from the Ministry of Health and Social Development of the Russian Federation in 2009-2020 showed that only 25-30% of Russian women of childbearing age used contraception. This low usage is linked to several factors, including the underdevelopment of the domestic industry for producing modern hormonal contraceptives, irregular and costly government procurement, and a lack of public awareness about the availability of newer contraceptive options. Additionally, economic downturns—such as the financial crises of 1998 and 2020—led to steep increases in the prices of medical drugs, making them less accessible for many women. In recent years, there has been an increasing recognition within society of the importance of family planning, sex education, the cultivation of family and moral values, and the promotion of a healthy lifestyle. There is also a growing emphasis on responsible parenthood, particularly in encouraging young people to embrace responsible motherhood and fatherhood. This awareness has become particularly pressing in light of the significant challenges related to reproductive health. One notable response to these issues in Russia was the adoption of the Family Planning** program in 2024. This program aimed to address reproductive health challenges and promote the well-being of families.

Building on the success of the national initiative, a regional Family Planning and Reproductive Health Protection program was also adopted and partially implemented in the Sverdlovsk region. This program proved effective in reducing the number of abortions and lowering maternal mortality rates. It was later combined with the Safe Motherhood program, further contributing to improvements in reproductive health outcomes.

Global experience demonstrates the value and high medical and social effectiveness of such programs. In many Western European countries—including Finland, Sweden, the Netherlands, France, and England—family planning and reproductive health programs have been in place for over 40 years. These countries have achieved optimal levels of contraceptive use, which have significantly reduced maternal mortality and abortion rates. Furthermore, the concept of "abandoned children" is almost nonexistent in these nations, illustrating the far-reaching positive impact of comprehensive family planning policies. The success of these programs highlights the importance of sustained efforts in reproductive health education and family planning for the overall well-being of society.

Since 1978, the concept of primary health care (PHC) has undergone various interpretations and definitions, causing confusion in the understanding of the term and its practical application. To ensure more coordinated action at the global, national and local levels, the following definition has been proposed:

“PHC is an integrated approach to health that covers the whole of society and aims to achieve equitable access by every member of society to the highest possible level of health and well-being. It addresses the needs of the population at the earliest stages, providing a wide range of services, from health promotion and disease prevention to treatment, rehabilitation and palliative care, as close as possible to people’s daily lives.” This definition has been developed by WHO and UNICEF within the framework of the PHC concept for the 21st century, with a focus on achieving universal health coverage (UHC) and the Sustainable Development Goals (SDGs).

The PHC system includes three interrelated components:

1. A comprehensive set of health services, with an emphasis on primary health care, public health and related functions.

2. Intersectoral policies and actions that address the key determinants of health.

3. Engaging and empowering individuals, families and communities to actively participate in managing their health and social lives.

The concept of PHC is based on the values of social justice, equity, solidarity and cooperation. It is based on the recognition that the enjoyment of the highest attainable standard of health is a fundamental human right, regardless of status or condition.

Achieving true universal health coverage requires a shift from disease-focused systems to people-centred and participatory systems. This requires governments at different levels to recognise the importance of action beyond the health sector to implement a whole-of-government approach to health, with a particular focus on equity and the entire life course.

The concept of PHC aims to address a wide range of determinants of health and pays attention to the integrated aspects of physical, mental and social health. This approach ensures high-quality and comprehensive care at all stages of a person’s life, not just the treatment of individual diseases, with a focus on maximum proximity to the patient’s place of residence.

While there have been notable achievements in building primary health care (PHC) systems and health networks in Latin America, as reflected in key health indicators, there are still critical issues that need to be addressed based on the evidence analyzed. First, while the concept of PHC is embedded in institutional discourse and sectoral debates across the region, it faces significant challenges from the organizational structures of health systems. Intense fragmentation, ineffective decentralization, and the accumulation of isolated programs along the care continuum have led to the consolidation of a care model that deviates from best practices.

Profound income inequality acts as a segmentation mechanism, creating different levels of coverage based on individuals' ability to pay. In recent decades, most countries in the region have made efforts to promote coordinated care models, but results have been uneven, and monitoring and evaluation of the impact achieved have been scarce. The limited coordination between subsystems amplifies disparities, leading to the development of fragmented health networks that often operate informally and without standardized protocols. Collaboration between providers within different subsystems is minimal, and the private sector does not function as a space for coordination and complementarity with the public sector or, in some cases, social security systems. Instead, it often exacerbates care gaps.

The evidence gathered for this review has highlighted several key themes discussed throughout the document. Most notably, there is a pressing need to strengthen PHC models and care networks, as indicated by the documented results. Additionally, the review identified gaps in coverage of other critical topics, such as how health systems adapt to evolving population needs and the accumulation of epidemiological challenges, including mental health issues, addictions, and environmental impacts.

Furthermore, this review found a lack of literature on the impact of financial and non-financial incentives on health service provision, resource allocation efficiency, and quality improvements, opening avenues for future research. This gap suggests a need for deeper interaction between research and political action in the Latin American and Caribbean region to facilitate information exchange, strengthen the evaluation of interventions, and jointly design a research-action agenda that has a meaningful social impact. Article of law 35 of the "Fundamentals of the Legislation of the Russian Federation on the Protection of Citizens' Health" guarantees the right to assisted reproductive technologies for all adult women of childbearing age. Specifically, the article states that "every adult woman of childbearing age has the right to artificial insemination and embryo implantation." These procedures, which include artificial insemination and embryo implantation, can be carried out in licensed medical institutions, provided there is written consent from the woman involved. Furthermore, information regarding these procedures, as well as the identity of the donor, is protected as a medical secret.

If a woman has medical conditions that prevent her from carrying a pregnancy to term, as outlined in Order No. 67 from the Ministry of Health of the Russian Federation, she is eligible to use the services of a surrogate mother. The indications for surrogacy under this order include:

- Absence of the uterus (either congenital or acquired),
- Deformation of the uterine cavity or cervix, which may impede pregnancy,
- Somatic diseases in which carrying a pregnancy is medically contraindicated,
- Repeated unsuccessful IVF attempts despite the transfer of high-quality embryos.

In cases where these medical conditions are met, a woman may also opt to use the services of an oocyte donor or a donor embryo to achieve pregnancy. This legal framework thus provides women facing fertility challenges with multiple avenues for starting a family, ensuring access to modern reproductive technologies based on their medical needs.

As of today, approximately 100 clinics in Russia specialize in reproductive medicine. These clinics receive funding from the federal budget as well as from the budgets of various constituent entities of the Russian Federation. However, the cost of in vitro fertilization (IVF) procedures is relatively high, and almost all clinics have long waiting lists for those seeking free IVF quotas. As a result, many married couples and single women find this essential service to be financially out of reach.

Additionally, there exists a category of social infertility, which refers to healthy individuals who wish to have children but are unable to do so due to legislative shortcomings. A significant legal gap in Russian family law is the lack of clarity regarding the rights of unmarried individuals to access assisted reproductive technologies (ART), particularly in relation to surrogacy and donor programs. This issue affects millions of formally unmarried individuals of reproductive age. According to the 2002 census, around 30 million people expressed a desire to remain unmarried or had not yet found a partner, comprising approximately 15 million men (aged 18-54 years) and 14 million women (aged 18-44 years).

Over the past two decades, Russia has experienced a natural decline in its population, making it increasingly unlikely to see a substantial rise in the birth rate in the foreseeable future. To address this issue, it is essential to create conditions that enable individuals suffering from physiological infertility—regardless of marital status—to fulfill their desire to become parents. Advances in reproductive technologies present new opportunities to tackle the challenge of increasing birth rates in the country.

The Russian government should expand its support for individuals wishing to have children through surrogacy and reproductive programs. This includes increasing funding for clinics that specialize in therapies for male and female infertility. Furthermore, the reproductive rights of citizens require legislative protection, as their realization is directly tied to governmental support. Currently, there is no specific law in Russia that officially classifies infertility as a disease that warrants treatment, rather than merely a condition. Therefore, liberalizing the legal framework surrounding the desire to become parents is a crucial component of demographic policy. This would help ensure that all individuals, regardless of their marital status, have access to the reproductive technologies they need to start families.

Abstract

This article investigates important conceptual approaches to the transition to a "green economy" in the context of sustainable development of Kazakhstan. Theoretical foundations of the problems of transition to a low-carbon economy are carried out, important directions and stages in the transition to a "green economy" are shown, as well as considered foreign experience of mechanisms for the implementation of large-scale transformations on the transition to a "green economy" on the example of some countries. In order to ensure the reliability of the obtained results, the authors have addressed various sources on the available issues by the method of express analysis and interviews. The results of these scientific and experimental activities were reflected in the scientific work. The appendices and tables given in the work give quality to the work, clearly characterize and substantiate the theoretical conclusions and proposals. Certainly, we can state that this study has achieved its goal, the results of the study are fundamentally new, the work contains a number of sound recommendations for further transition to a "green economy" in the conditions of sustainable development of Kazakhstan will contribute to the economic growth of our country.

Keywords*:* investments, sustainable development, strategy, green economy, target indicators, SDGs, energy

I. Introduction

Transition to a "green economy" is the main way to achieve the SDGs, to fulfill Kazakhstan's promised contribution to reducing greenhouse gas emissions under the Paris Agreement with economic and environmental sustainability, a just and prosperous society, and a clean and healthy environment. The long-term vision of transition to a "green economy" for Kazakhstan is relevant for all key sectors of economic development.

Due to its undeniable merits, we believe that the adopted Strategy "Kazakhstan-2050: a new political course of the established state" (hereinafter - Strategy - 2050) sets clear guidelines for building a sustainable and effective model of the economy based on the country's transition to a "green" path of development. Due to its undeniable merits, we believe that the adopted Strategy "Kazakhstan-2050: a new political course of the established state" (hereinafter - Strategy - 2050) sets clear guidelines for building a sustainable and effective model of the economy based on the country's transition to a "green" path of development.

Transition to a "green economy", which can be defined as a successful economy with a high standard of living of the population, careful and rational use of natural resources in the interests of future generations and in accordance with the international obligations assumed by the country, is beneficial for Kazakhstan and will allow the country to move closer to its goal of becoming one of the 30 most developed countries in the world. It is estimated that by 2050, the transformation of the green economy will allow for an additional 3 percent increase in gross domestic product (GDP), the creation of more than 500,000 new jobs, the creation of new industries and services, and healthier and more equitable living conditions for the population. The transformation requires combined public and private investment averaging about 1 percent of GDP annually. Transition to a "green economy", which can be defined as a successful economy with a high standard of living of the population, careful and rational use of natural resources in the interests of future generations and in accordance with the international obligations assumed by the country, is beneficial for Kazakhstan and will allow the country to move closer to its goal of becoming one of the 30 most developed countries in the world. It is estimated that by 2050, the transformation of the green economy will allow for an additional 3 percent increase in gross domestic product (GDP), the creation of more than 500,000 new jobs, the creation of new industries and services, and healthier and more equitable living conditions for the population. The transformation requires combined public and private investment averaging about 1 percent of GDP annually.

II. Literature review

"Green economy" as an economic form of green development, includes low-carbon industry, energy-saving and environmental protection industry, ecological economy and renewable energy and other. The development of green economy is not only a strategic measure for long-term development, but also an important component of the current development of Kazakhstan's economy.

In recent years, many researchers have paid attention to the relationship between economic growth and the environment. Since the effects of environmental problems such as global warming, air pollution, increased use of natural resources and emissions, environmental and energy issues have gained paramount importance in the field of economic growth on international platforms [1-10].

It is often noted by researchers that green finance is becoming an important component for achieving global and national sustainable development goals and building a green economy, defining new environmentally sustainable growth prospects for the green segment and responsible investment [2].

There are opinions that to achieve the goals of sustainable development and transition to a "green" economy requires not only significant financial resources, but also the transformation of traditional investment. In the modern period, in the context of the world's global aspiration to sustainable development for investment projects and industries aimed at improving in the context of the world's global aspiration to sustainable development, the development of green economy and green financial instruments is relevant [3].

Many researchers have attempted to identify the main factors affecting energy consumption. They use population growth rate, balance of trade in goods and services, GDP, foreign direct investment and energy prices as determinants of energy consumption. And here we can agree with the opinions of these researchers, as their results show that the growth rate of direct investment in the energy sector affects both GDP growth and the levels of energy consumption of the population [4].

Some works clearly define the essence of responsible investment within the concept of ESG-investment, which takes into account the unity of environmental, social and corporate governance factors; they analyze the state and development of responsible investment factors and assess the possibilities of forming an ecosystem of financial support for environmentally responsible investments [5].

According to experts, they point the main problems in the transition to a "green" economy to the processes of regulation in the sphere of environmental management, in particular, in the oil industry. They note that the mechanisms of regulation of the industrial waste processing industry are practically absent, and the problems arising in this industry are ignored by authorized bodies, which can lead to an environmental disaster [7].

III. Methods

In conducting this study as a methodological basis were used general and specific methods, in particular: dialectical, system-functional, economic-statistical and formal-logical methods. Currently, the issues of conceptual approach to the transition to a "green economy" have been reflected in many scientific studies. However, it should be noted that there is not enough theoretical review on the problems of transition to a "green economy" in the context of sustainable development of the national economy. To date, the national economy has formed certain methods and approaches to further transition to the "green economy". However, none of them can be considered universal for the study of this process. Based on the above methods, we note that the research methods are built on the principles of system-structural analysis, methods of scientific analysis and synthesis were applied.

IV. Results

Currently, our country is implementing the National Project "Green Kazakhstan" for 2021-2025 in order to transition to a "green course" of economic growth is a very high priority and strategic task of the national economy.

The main priority areas in the transition to a "green economy" are the following (Fig. 1):

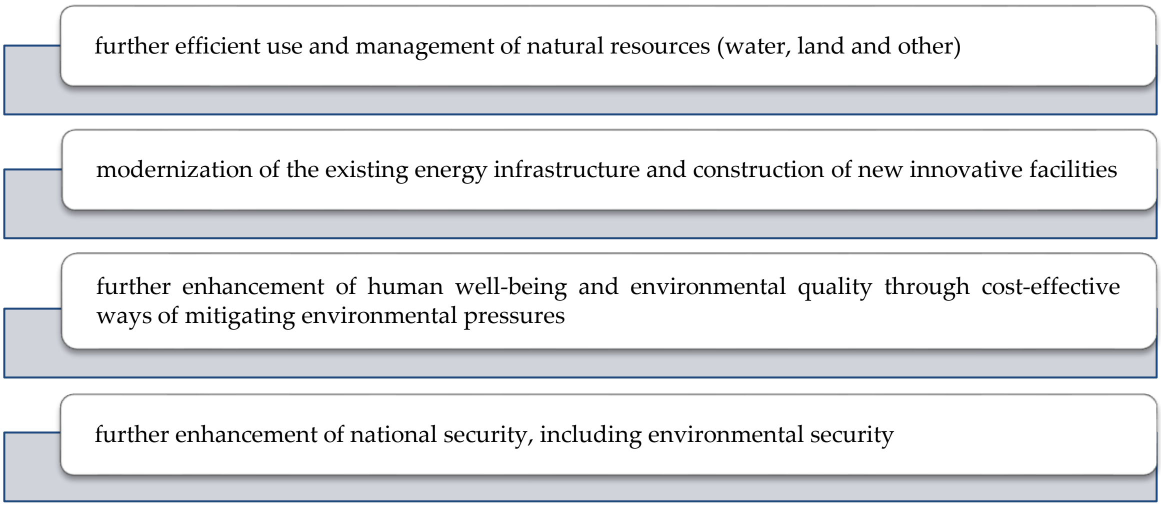

Figure 1: *Main directions for transition to "green economy"*
Source: Concept on Transition of the Republic of Kazakhstan to "green economy" [5, 6]

The total amount of investments required for the implementation of the Concept on the transition of the Republic of Kazakhstan to a "green economy" of May 30, 2013 (hereinafter the Concept) from now until 2050 will average 3-4 billion USD annually. The largest annual volume of investments will be equivalent to 1.8 % of GDP in the period from 2020 to 2024, and on average until 2050 investments will amount to about 1% of GDP. At that, the main share of investments will be attracted at the expense of private investors' funds [5, 6].

According to this Concept, the asset renewal cycle in resource-based sectors of the economy takes a long time, and in resource-based economies the transition to a clean economy takes decades. Kazakhstan is not an exception in this sense (Fig. 2).

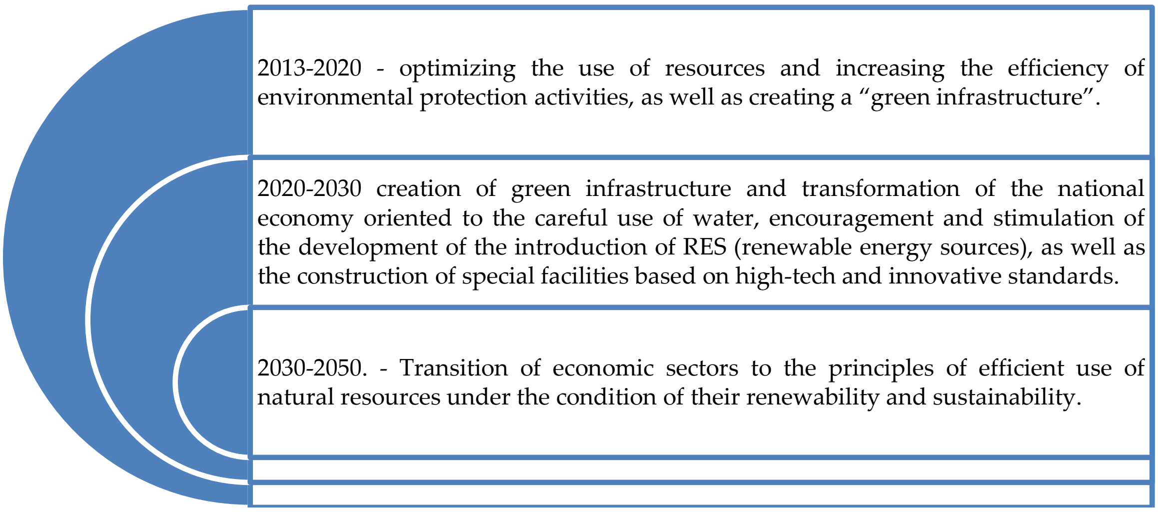

Figure 2: *Important stages of implementation of the Concept for the transition of the Republic of Kazakhstan to a "green economy" Source:* http://egov.kz/wps/portal/Content?contentPath=/egovcontent/bus_nat_eco/ecologiya/article/green_ekonomika&lang=ru [7]

Such measures should contribute to changing the behavioral patterns of the population with regard to the use of heating and cooling systems, waste disposal and water use [8].

To coordinate and control the transition to a "green economy" the Council on Kazakhstan's transition to a "green economy" will be established under the President of the Republic of Kazakhstan. This Council will review the National Report on the transition to a "green economy" every three years. Establishment of such a body is a mechanism for realization of large-scale transformations in the public sector. For example, this approach has been successfully used in Taiwan, Korea and Bahrain (Table 1).

Table 1: *Key effective approaches in the transition to a green economy in some countries*

Country	Program	Expected results
Taiwan	Reconstruction of rural areas	▪ The organization responsible for change should not replace ministries, but complement them ▪ Opportunities should be provided for innovative developments to address identified problems ▪ Local skills should be developed to sustainably implement the solutions developed in the future.
Korea	National economic development plan	▪ The organization has very broad powers and has the full support of the Prime Minister ▪ It is directly linked to the Ministry of Finance and has full control over the budget. ▪ The organization is made up of only the most effective professionals from both the public

		sector and the emerging private sector. ▪ The organization functions as an "incubator" - it has already established several independent companies that have subsequently become leading players in the private sector.
Bahrain	Bahrain's Vision 2030 Economic Development Plan	▪ There should be an optimal mix of experienced professionals and young professionals with high potential ▪ Opportunities should be created to attract top-notch talent without unduly high remuneration ▪ The responsible organization should be given significant weight through the broad powers granted to it by the country's leadership ▪ The necessary authority to make or influence budget allocation decisions should be ensured.

Source: [6-9]

Based on the data in Table 2, showing the dynamics of electricity production from 2018 to 2022 in Kazakhstan, it is possible to assess the state of production, consumption of electricity in Kazakhstan. During this period, the average tariff, which is 15.66 tenge per 1 kWh in 2022, increased several times, while electricity production increased by about 2 times. At the same time, if we correlate electricity production and consumption, we can highlight that from 2018 to 2021, consumption exceeded production [6-26].

Table 2: *Dynamics of electricity generation, consumption and estimated electricity tariff in Kazakhstan for 2018-2022*

Indicators	2018	2019	2020	2021	2022
Electricity production, billion kWh	107,27	106,48	108,63	115,08	113,45
Electricity consumption, billion kWh	103,20	105,10	107,30	113,50	112,94
Settlement tariff (average), tenge per 1 kWh	11,07	10,53	11,74	14,04	15,66

Source: [10]

However, taking into account the forecast of electricity generation and consumption in Table 2, it can be seen that after 2022 there is a probability of electricity shortage. The data in Table 2 show a downward trend, which will be realized starting from 2022 for 4-5 years. In general, the following will be envisaged to reduce consumption: increase in tariffs, which will be for all consumers of electricity; formation of new sources of production by attracting different types of electricity generation and saving of electricity received by the population [6-26].

V. Discussions

In the context of sustainable development of Kazakhstan's economy, the importance of both the implementation of the Concept and the realization of the 17 Sustainable Development Goals (SDGs), put forward by the UN in 2015 to all countries of the world to ensure economic security, in particular, environmental security, reducing emissions of environmental protection and environmental protection is increasing

For this purpose, let us consider the main goals of the SDGs realization (Figure 3). For the realization of 17 SDGs Kazakhstan has developed its national indicators, monitors and evaluates their implementation. These activities take place both on the national scale as a whole and at the regional level.

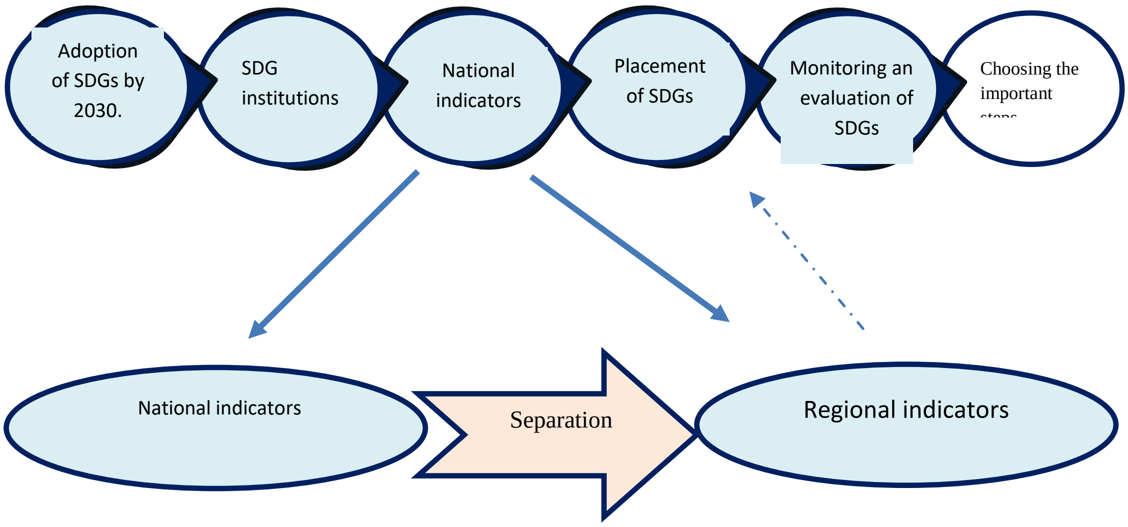

Figure 3: *Main objectives of SDG implementationy*
Source: [11]

Thus, the concept of transition of the Republic of Kazakhstan to a "green economy" is implemented in accordance with the provisions of the Constitution of the Republic of Kazakhstan, Strategy 2050 and the Strategic Development Plan of the Republic of Kazakhstan until 2020. Issues of implementation of the transition to a "green economy" will be regulated by legislative acts of the Republic of Kazakhstan on the transition to a "green economy". At the same time, the transition to a "green economy" reduces risks from global threats such as climate change, depletion of minerals and shortage of water resources

VI. Conclusion

In the process of transition of Kazakhstan some researchers consider the development and establishment of green finance in Kazakhstan. conceptual approaches to the transition to “green economy” in the conditions of sustainable development of Kazakhstan. Many literatures refer to numerous studies conducted on the principles of green economy, as current models of economic growth and development are unsustainable. The level of participation of private and public institutions in the process of implementing the principles of “green economy” varies depending on the level of economic development of the country.

“Green economy” is an inclusive system of economic growth, social protection and natural ecosystems when it does not create serious risks and environmental deficits for future generations. The link between environment and development is possible through sustainable development. Thus, it is noted that the green economy is based on the restructuring of growth and development within the framework of global resources. Various stakeholders are involved in the process of implementing the principles of green economy, and each of them plays a fundamental role. “Green economy” is an inclusive system of economic growth, social protection and natural ecosystems when it does not create serious risks and environmental deficits for future generations. The link between environment and development is possible through sustainable development. Thus, it is noted that the green economy is based on the restructuring of growth and development within the framework of global resources. Various stakeholders are involved in the process of implementing the principles of green economy, and each of them plays a fundamental role.

Thus, in the green economy, concepts such as sustainable products, clean technologies and green processes have pushed organizations to opt for change management initiatives. Organizational sustainability through application has been defined as a triad concept covering environmental issues, economic aspects and social issues. The European Union has developed a set of environmental policies, the main ones being environmental sustainability, a natural capital economy and resource-efficient and environmentally friendly development.

Abstract

To date, the generally recognized global trends have become the principles of sustainable development adopted by the UN, which are understood as the evolutionary development of civilization based on innovations while meeting the vital needs of the population of different states, including energy supply and environmental conservation. Being associated with a number of crises, the growing turbulence of the global economy and the political system of the modern world, constantly seeing an increase in the number of challenges to global trends towards sustainable development, it is worth reconsidering the approach to the concept of Sustainable Development. Attempts to undermine the significance of the UN 2030 Agenda for Sustainable Development adopted in 2015 under the influence of the COVID-19 pandemic quickly gave way to the importance of uniting efforts aimed at achieving the 17 Goals that are the basis of governance (SDGs). Efforts at many levels - from states and their regional entities to municipalities, corporations, or ultimately the level of specific people in society by and large. Attention to sustainable development issues is also growing against the backdrop of an obvious deterioration in the climate situation and the need to create energy security.

Keywords: sustainable development, greenhouse, gas emissions, environmental challenges, environmental protection, advanced technologies

I. Introduction

Modern technologies become part of any business and serve as a key factor in ensuring its competitiveness [1]. However, complex technologies have limitations that do not allow them to fully use their full potential to solve the problems of the ESG agenda. The first limitation is due to the fact that the use of advanced analytics technologies requires huge computing power, and this, in turn, leads to an increase in energy consumption and entails an increase in carbon dioxide emissions, negatively affecting the company's ESG indicators and the environment as a whole [2]. The second limitation is the ethical aspects of new technologies. Cloud computing can be one of the solutions to circumvent the above limitations. They respond to environmental challenges through more efficient energy management. The solution of the ethical aspects of new technologies in the clouds is achieved by standardizing the algorithms of the models used, using a huge amount of data, and constantly checking and validating the results. Now modern technologies are becoming a part of any business and serve as a key factor in ensuring its competitiveness. For example, with the help of advanced analytics, the most resource-intensive, complex and non-trivial tasks are already being implemented, the solution of which was previously impossible or impractical due to huge time and material costs [3]. Technologies allow you to analyze a huge amount of data in a short time, provide self-learning models and identify complex relationships, build accurate forecasts, collect information and analyze, respond to changes in production indicators online, as well as securely store this data and much more. Digital tools based on sophisticated analytics are also applied to companies' internal processes to improve their efficiency. For example, advanced technologies are widely used in the world to solve problems in the field of ESG. In the Russian market, the share of penetration of modern technologies into ESG is small, however, according to a joint study by the audit consulting company Trust Technologies (hereinafter referred to as TeDo) and the Center for Sustainable Development of the SKOLKOVO School of Management, 65% of leaders of large Russian companies believe that without digital solutions it is impossible to implement ESG transformation. For example, in the field of ecology and climate (E), artificial intelligence technologies can achieve the goal of the agenda by creating smart and low-carbon cities, Internet-of-Things-based devices that can regulate electricity consumption. They also help improve the integration of renewable energy sources through smart grids and identify desertification trends through satellite imagery.

II. Methods

As part of the social aspect (S), it becomes possible to create safer working conditions for employees. In the management part (G), thanks to the use of advanced technologies, reporting is automated, which becomes more transparent and accessible to the public. As the mentioned study shows, the following technologies have the greatest potential for achieving maximum efficiency in solving ESG problems [4]:

- artificial intelligence (29%);
- internet of things (23%);
- blockchain (14%).

However, it should be noted that for the implementation of specific digital solutions for ESG, combinations of these technologies are often used, which complement and enhance the effectiveness of each other. Let's consider the most common examples of using the technologies under consideration for the entire spectrum of tasks in the field of ESG.

The combination of artificial intelligence and the Internet of things is an indispensable tool for tackling climate and environmental issues, such as managing a company's carbon footprint. On the basis of artificial intelligence technologies, data are collected and consolidated reflecting the emission and absorption of greenhouse gases from production sensors in the context of individual processes. The specified array is further converted using machine learning into predictive models that allow high-precision assessment and optimization of the company's processes. According to Accenture research, more than 70% of companies report the effectiveness of digital emission reduction solutions implemented using artificial intelligence. Combining artificial intelligence with blockchain technologies makes it possible to more transparently track the carbon footprint formed by the components of the company's products throughout the supply chain and for all types of coverage (Scope 1, 2 and 3). An example of a digital carbon footprint management tool is a solution to reduce energy intensity implemented by a large steel company. Thousands of sensors collect data, which is then processed by artificial intelligence algorithms. This allows the company to accurately calculate and predict energy needs, and track and reduce emissions. Since implementing the solution, the company has implemented a number of initiatives that, according to BCG, resulted in a 3% reduction in carbon dioxide emissions, which is approximately 230 thousand tons of CO_2 per year, and reduced costs by $40 million.

III. Results

According to a McKinsey study, more than 20 examples of using artificial intelligence to improve the quality of life and health of company employees and 3 examples of gender equality stand out in order to achieve the sustainable development goals [5]. These goals are included in the social aspect of the ESG agenda. The most striking example of the use of artificial intelligence in the social sphere is the implementation of solutions that provide safe working conditions. On the basis of data received from surveillance cameras, self-learning models are formed that recognize standard operating conditions and deviations from the norm. Further, the data from surveillance cameras is analyzed online and, using predictive analytics, hazardous work areas and risks are identified that can lead to incidents at the workplace in the future. For example, it is possible to track the movements of employees and identify potential hazards along their routes, such as the danger of tripping or the presence of loose equipment. With the help of such solutions, it becomes possible to set up notification of managers and staff about emerging risks and security incidents in the workplace, which allows them to be eliminated in a timely manner. Updating and processing data in real time allows you to monitor employees who violate established security rules. Internet of Things technologies complement and increase the efficiency of the digital solutions discussed above based on artificial intelligence. With the help of special sensors and thermal imaging cameras, data is collected about the environment surrounding the company's employees and its safety is assessed. For example, some companies are using machine vision to monitor employee safety in hot work areas. In particular, thermal imaging cameras can be used to detect "heat stress" in workers and provide them with the necessary assistance in the form of a cool down break or additional personal protective equipment. Sensors are also used to analyze the composition of the air in the working room [6]. They scan, analyze and immediately report the presence of harmful particles, pollutants or hazardous gases such as carbon monoxide. By collecting and analyzing air quality data and alerting anomalies, such systems help prevent the release of harmful pollutants into the atmosphere, while maintaining the safety and health of every employee. Additionally, with the help of artificial intelligence and the Internet of things, it becomes possible to create smart offices focused on maintaining the health, well-being and safety of company personnel. Occupancy sensors keep track of the number of people in the office at a given time. The visualization of such data enables flexible working formats, such as shared desk systems, and facilitates social distancing and prevents overcrowding in the workspace. Employees have access to this data to decide whether to visit the office. Also, office attendance data allows real-time implementation of office cleaning planning models that take into account their use. The level of air quality also affects the safety of personnel. A high amount of carbon dioxide in the air is associated with poor decision making, lack of concentration and drowsiness. Air quality sensors measure the level of carbon dioxide and volatile organic compounds and display the data on the dashboard to adjust the working environment of office workers accordingly. An industrial security video analytics project implemented by a large Russian company, which includes monitoring of hazardous areas, the use of PPE (personal protective equipment), collision risks and a number of other aspects, is an example of the implementation of a solution based on modern technologies in terms of the S-component. All collected data is analyzed in order to completely prevent accidents. In the near future, it is planned to equip employees with portable devices that allow monitoring biorhythms and monitoring critical health conditions, including pre-infarction and pre-stroke, which carry a great danger, especially when operating complex equipment, because in the event of an unexpected deterioration in health, the life of the employee himself is at risk, and his colleagues [7]. By connecting portable devices to the on-board computers of the technician, an instant stop of traffic will be provided, notification of those responsible for the site, and, most importantly, a call for an ambulance brigade, which upon arrival will have all the necessary data on the state of a person for prompt assistance.

RT&A, Special Issue № 6 (81), Part-3,
Volume 19, December 2024

IV. Discussion

Modern technologies also make it possible to successfully implement solutions aimed at impartial evaluation of work and professional development of employees. With the help of big data analytics and artificial intelligence, a large financial holding has developed a personnel assessment system that solved the problem of biased feedback due to collusion between employees. This decision, based on the analysis of information about 25 thousand employees and more than 125 million emails, identified informal leaders who are most actively and effectively involved in decision-making and task completion. It was found that the intersection of the list of candidates for promotion, compiled by employees, and opinion leaders, determined by the decision based on artificial intelligence, is only 60%. Thus, employees whose promotion is premature were identified, and in general, transparency and impartiality were added to the decision-making process on the promotion of employees. Artificial intelligence-based solutions aimed at training and professional development of employees allow the formation of personalized recommendations of the most relevant courses for an individual employee based on user clustering and training programs. The accuracy of the recommendations is achieved by analyzing the test results, personal profile, requirements for the position, as well as user experience. A similar solution is used by one of the largest banks in Spain. Another example of a more responsible attitude towards employees is the use of big data to prevent professional burnout [8]. The most striking example is the experience of a large construction company, which, using analytics and big data structuring, revealed that 14% of employees are in the last stage of burnout. The decision made it possible to apply employee support measures in a timely manner and reduce the level of staff turnover.

Good governance requires full transparency and accountability for key processes. With the help of artificial intelligence-based solutions, it becomes possible to automate the formation of key ESG indicators, which allows for a transparent, versatile and unbiased analysis of the company, eliminating the risk of human error in calculations, as well as their distortion. The main problem of automating the generation of ESG reporting is the heterogeneity of the required data sources. It is solved by using NLP (Natural Language Processing) algorithms, which allow machine learning to be applied to text written in natural language. Artificial intelligence-based solutions are already on the market, which, through full integration into company processes, allow collecting and processing data, calculating ESG metrics and comparing indicators with market averages. An additional reporting requirement under this aspect is to ensure the traceability of reporting and the possibility of its audit, which can be achieved through a combination of artificial intelligence with blockchain technologies. This decision allows you to confirm the immutability of the data reflected in the company's financial statements. All data stored on the blockchain platform can be verified by regulators or an independent party to confirm the company's compliance with the established standards and to verify that its statements, messages and advertisements correspond to its actual practice. For example, many corporations have committed to significantly reduce or eliminate their carbon footprint, which is reflected in corporate goals. Thanks to blockchain technologies, these goals can be compared with the organization's current carbon footprint. The above examples show that global problems in the field of sustainable development are currently being effectively addressed through the use of advanced technologies [9]. However, complex technologies have limitations that do not allow them to fully use their full potential to solve the problems of the ESG agenda. The first limitation is due to the fact that the use of advanced analytics technologies requires huge computing power, which leads to an increase in energy consumption and entails an increase in carbon dioxide emissions, negatively affecting the company's ESG indicators and the environment as a whole. In practice, training artificial intelligence models requires a huge amount of computing power, and some researchers argue that the environmental costs of applying advanced analytics outweigh the benefits. By some estimates, in just a few years, the digital industry will generate more carbon emissions than all road transport. Digitalization already accounts for 4% of global greenhouse gas emissions, according to EY analytics. The ecological footprint of the digital world is constantly increasing as energy consumption grows in parallel with the growth of the industry as a whole to meet the demand for technology. Some experts believe that by 2025 the technology sector could consume 20% of all electricity in the world. This growth from the current 7% is logical against the background of the development of complex technologies, such as artificial intelligence, which contribute to the demand for computing power. The second limitation is the ethical aspects of new technologies, in particular artificial intelligence. In most cases, historical data (often from a single company) is used to train artificial intelligence models, which can be limited and biased and lead to gender or racial inequality and discrimination from the decision based on such a model. An example is a scientific experiment led by researchers from Johns Hopkins University, Georgia Institute of Technology and the University of Washington. Robots, functioning on the basis of artificial intelligence, were asked to distribute people into certain social roles and professions according to their appearance. The main conclusions of the study are as follows [10]:

- fair-skinned women in most cases were classified as housewives;
- black men were 10% more likely to be identified as criminals;
- Women were practically not assigned to medical professions. This observation is a significant limitation for the use of new technologies in the field of the social aspect of the ESG agenda, since it directly contradicts the task of this aspect. Cloud computing can be one of the solutions to circumvent the above limitations. Cloud technologies respond to environmental challenges through more efficient energy management. The solution of the ethical aspects of new technologies in the clouds is achieved by standardizing the algorithms of the models used, using a huge amount of data, constantly checking and validating the results.
